VOL. CLII.

WEDNESDAY, JANUARY 5, 1916.

No. 1.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

IT is, of course, quite impossible for us in this country to gauge the amount of truth in the rumours concerning the Kaiser's health. For several years past there has been talk of William II. being troubled with an affection of the throat, which was said every now and again to give cause for anxiety. Then there have been suggestions of an affection of the ear; it was even positively stated that an operation had been performed, but nothing definite was ever made public. The fact that both his parents died of malignant disease was sufficient to give colour to the suggestion that any and every minor malady from which he suffered was in reality of a cancerous nature. He is certainly at the age when malignant disease is liable to show itself, and worry and anxiety, which are considered to be contributory causes, can scarcely be absent in his case.

SOME of us are old enough to recall the dramatic circumstances surrounding the death of his father, the Emperor Frederick, who undoubtedly died of cancer of the throat. A great deal of feeling was aroused in Prussia, and indeed all over Germany, not only in medical circles, but also in circles political, by the fact that it was an Englishman, Sir Morell Mackenzie, who was given full charge of the case, and remained with the Emperor until the latter's death. This affront to German skill and German knowledge in matters laryngological was attributed to the influence of the Empress Frederick, who was the eldest daughter of Queen Victoria.

WHEN he returned home, Mackenzie wrote a book entitled "The Fatal Illness of Frederick the Noble," which created a great sensation. Therein he described the difficulties which were put in his way by the Court and military etiquette, the jealousy of the German physicians and surgeons, the thinly-veiled antagonism of the statesmen from Bismarck downwards, the insolence of the Crown Prince, now William II., and the general atmosphere of distrust and dislike which he and his colleague, Mr. Mark Hovell, were obliged to encounter. By the Emperor and his

Consort, however, he was rewarded by the most perfect courtesy, constantly expressed gratitude, and unbounded confidence.

IN the course of the book Mackenzie described a scene which was evidently intended to convey the impression that von Bergmann, who was also in attendance as chief surgeon, visited his illustrious patient on one occasion in a state of intoxication; and a facsimile of the patient's written comment on von Bergmann's behaviour was reproduced. This was considered unjustifiable by the College of Physicians, who thereupon demanded that Mackenzie should resign his membership. This not very tactful intervention was very severely criticised both by the profession, who regarded it as unwarrantable interference, and by the public, who made merry over the "rules of etiquette" which preclude a man in possession of overwhelming evidence to prove his case from producing that evidence in order to rebut outrageous attacks levelled at him by German detractors. I wonder whether the College of Physicians would behave similarly in the face of the present feeling about matters Teutonic.

ON the subject of the title "German Measles," which has been discussed in these columns, a correspondent suggests that the word "German" occasionally means "spurious," e.g., German silver, German tinder. He refers me to the 1852 edition of Hoblyn's "Dictionary of Medical Terms," which, under "German Paste," gives the following, and asks what it was used for. I fear I cannot say. Can any reader enlighten him? "Beat together lbij of pease flour, lbj of blanched sweet almonds, three ounces of fresh butter, the yolks of two fresh eggs, with a little honey and saffron; heat the mass gently and pass it through a sieve, to form it into grains."

NOR once, but several times, have I declaimed against the selfishness and want of consideration of people who whistle for taxis. This is the only capital in the world where such a thing is allowed, and it is an abominable scandal that it should continue to be tolerated. Here is a

German
Measles.

Street
Noises.

letter recently addressed to the *Times*, which will, I trust, do something to awaken public opinion on the subject. It is signed "Three Wounded Officers": "May I ask you to insert this appeal on behalf of a number of wounded men in private and other hospitals in the West End of London, in the hope that it may stop the selfish whistling for taxicabs that renders rest and sleep almost impossible? During Christmas the whistling, always excessive, has been unbearable. Many charming ladies are doing their utmost to care for us, and the best medical skill in the world is at our disposal, but the brutal and incessant whistling for taxicabs makes many of us wish we had not been sent home for recovery. Some years ago I remember reading in your columns about a prosecution of an unfortunate man for ringing a muffin bell. This occasional and not unpleasant sound is heavenly music compared with the shrieking that goes on intermittently during the day and violently up to and after midnight."

THIS evoked the following, from one signing himself "A Bad Sleeper":

A Remedy. "There is a very simple remedy for the distraction by town noises. Take a bit of paraffin wax (off a candle if need be) as large as the last joint of the little finger, warm it on the body until quite soft through, and press it into the ear until it touches all round. Not a hundredth of the sound will pass it. I have used this for years without any ill-effects, and it can be pulled out in a second. By all means educate motorists in humanity, but meanwhile save the patient's distraction." Now, apart from the fact that this is a remedy which a large number of people cannot tolerate (it fidgets them almost as much as the noises irritate) it is preposterous that the majority should have to resort to such expedients in order that the insignificant and selfish minority may make day and night hideous by whistling, hooting and klaxoning. The authorities responsible are presumably at Scotland Yard, and an earnest appeal to them should be made to deal with this matter of street noises boldly, comprehensively and quickly.

DR. MURRAY LESLIE is much to be congratulated on the outcome of the **Leslie's Action**, suit which he brought against Dr. Cassel's Medicine Co. In October last Dr. Murray Leslie delivered a lecture on "War Strain and its Prevention." The rest of the story, according to the *Manchester Evening News*, is as follows:—"It apparently occurred to the defendants that they might utilise this lecture for the purpose of advertising their own medicine or tablets. Accordingly there appeared in some of the provincial papers articles headed "A Doctor on War Strain," which consisted of a more or less accurate report of what Dr. Leslie had said, but which gradually developed into a recommendation of Dr. Cassel's tablets in such a way as to lead the uninitiated to believe that Dr. Murray Leslie had recommended them. The defendants had consented to pay a nominal sum for damages and the costs of the motion. Dr. Leslie, added counsel, was not out for damages." In the present state of the law, I

suppose Dr. Murray Leslie was well advised not to "go out for damages," but if ever anyone was entitled to them, he certainly was. In so far as damages can punish, the unauthorised use of a professional man's work for trade purposes ought to be severely punishable. In the existing state of the law, the only thing for a doctor to do is to bring such an action as Dr. Murray Leslie has successfully brought; but while heartily congratulating the latter, I must warn others who may be driven to take the same course that they cannot expect to meet with the same success. The law on the subject appears to be very vague.

Dr. O'Neill's Case.

ANOTHER law which is very vague is that which deals with drugs under the Insurance Act. In the case which is reported in some detail in another column, in which Dr. Bernard O'Neill sought an injunction to restrain the Middlesex Insurance Committee from surcharging him with £323 on account of alleged extravagance in prescribing expensive drugs, the judgment unfortunately was against Dr. O'Neill. Mr. Justice Rowlatt, who tried the case, seemed to think that, although the law was on their side, the Insurance Committee had not, to say the least, treated Dr. O'Neill very generously. It is obviously impossible for anyone but a supervising medical man to say what constitutes extravagance in prescribing. It is no pleasure to a doctor to prescribe an expensive drug or an expensive line of treatment; when he does this it is obviously for the sole reason that he believes it preferable to any other. In this instance it cannot even be suggested that the expensive drug or treatment puts money in his pocket. The case proves all too conclusively that it may do the reverse.

Wives of Warriors.

W. H. M. writes: "I am interested in your remarks concerning medical attendance on wives of soldiers. In these parts we decided to give free attendance to those who were worse off during the war, and the applicants were to be investigated by a ladies' committee. But the investigation has proved to be a mere formality, for every applicant gets an order. If she is not accepted by us there is a row, sometimes an awful row, and we are sworn at. A further result is that the wives and children come to us more readily than heretofore, and those who were insured drop their insurances. I agree that much of this kind of thing is our own fault, but I see not how it can be altered. The profession can never be got into line; a well-to-do or short-sighted or popularity-seeking practitioner will always spoil a combined effort."

Sir T. W. Parkinson.

OF the two members of the profession who figure as Knights Bachelor in the New Year's Honours List, one is a Scotsman and the other a Welshman. Dr. Thomas Wright Parkinson is, I believe, a native of Dundee. He graduated M.B., C.M. Edinburgh in 1890, and took his M.D. nine years later. He has now been in general practice in Belgravia for many years, and counts among his patients a great number of very

distinguished people. It is to be supposed that it was his services to the Prime Minister during the recent indisposition of the latter which gained him the honour upon which his many friends in the profession will unite in congratulating him. Not very many general practitioners attain to titular distinction. In this case it falls upon a thoroughly worthy recipient.

Sir Milsom Rees Mr. MILSOM REES is a Bart's man who took his double qualification in 1889, and the F.R.C.S. in 1892. He is already a C.V.O. He has now for some years been laryngologist to the

King's Household and to Queen Alexandra. Mr. Milsom Rees is one of the few instances of men who have taken high place in the profession without the advantage of a hospital appointment. Mr. Milsom Rees is above all a laryngeal therapist, and it is as such that he has deservedly made a great reputation. In addition to his purely professional distinctions he is a first-class golfer, a very agreeable companion and a good raconteur.

Dr. George Oliver. DR. GEORGE OLIVER, formerly of Harrogate, who has just died at Farnham at the age of 74, was not only a very successful spa physician, but also a very serious worker

in physiological medicine. In association with Professor Schaefer he did some notable work on blood pressure, and did much by precept and example to encourage the use of the manometer as a routine procedure. It was in the course of their work on blood pressure that these two observers stumbled upon some facts in connection with the suprarenals and other ductless glands which opened the door to a good deal of our latter-day knowledge of the subject. Oliver was a very painstaking and accurate investigator on typically sound English lines; he lacked the imagination and enthusiasm which mark, make and not infrequently mar the work of the Celt. His face was very familiar in medical gatherings up to about ten years ago, when he returned to Farnham to enjoy his well-earned leisure.

The Insurance Act. We shall publish next week the third and last article by "Delta" on "The Insurance Act in Being." These three articles have dealt with the present position of the Act and its workings in a very impartial spirit; they breathe an atmosphere of inside knowledge and are written with that pleasing under-current of humour which only a certain detachment can lend. "I will be calm, Sir, I will be calm," said Mr. Podgers, and foamed at the mouth, is the note which "Delta" seems to strike, and I strongly recommend his wit and wisdom to readers of the paper. The canvassing of the profession for war purposes seems likely to introduce a new complication into the working of the Act, for, as the *Times* says, it is difficult to see how the medical profession can be effectively canvassed without changes in the panel system.

The Panel System. THE working of the panel system has come in for a good deal of abuse, some of which is merited, but much of which is due to defects which are inherent in the system itself, defects which could not be overcome even by Heaven-sent administrators. Whether there be a workable substitute for the panel system is a question which

might very profitably be considered in the light of the present crisis. One of the chief complaints against the present working of the system so far as the medical officers are concerned is the necessity for clerking; time and temper are constantly being wasted on useless certificates for quite trivial ailments, and doctors do not love clerking. Another very serious matter from our point of view is the expenditure which the Act entails upon the community. Mr. Kingsley Wood has stated that the cost for the current year will be 25 millions, of which the State pays but seven millions. Administration accounts for 3½ millions.

SINAPIS.

THE TREATMENT OF WOUNDS.

IN addition to the unsatisfactory manner in which the organisation of the profession for war purposes is being conducted, there is another matter to which we desire to direct the attention of the War Office. It is that Sir Almroth Wright's views upon the proper treatment of wounds in war, entirely iconoclastic as they are, have been accepted without demur or investigation by the military medical authorities. Now, we yield to no one in our admiration of Sir Almroth Wright, and we gratefully acknowledge the excellent work he has done in many directions, but we do not forget that, being human, he is liable to err, nor do we fail to recall that he has on at least one occasion expressed himself on a matter of personal hygiene in a sense which did not enhance his reputation as a scientist. This matter of the proper treatment of wounds is at the moment probably the most important question in the whole field of scientific medicine. Sir Almroth Wright's views on the subject are very unorthodox; they run counter to the experience and teaching of two generations of surgeons; their application has not been productive of any results which justify the complete *volte-face* which they entail, and, most important of all, their scientific correctness is strenuously denied by independent workers of the highest credit and renown. Dr. Shaw-Mackenzie's original papers published in the *MEDICAL PRESS AND CIRCULAR* have conclusively shown that Wright's views are unsound, both in theory and practice, and the letter from a medical officer at the front which we published last week clearly shows that so far from being useless in the firing line, antiseptics are essential. It is sound advice which bids us beware of changing horses while crossing a stream. The particular stream which the country is at present engaged in negotiating is the broadest and roughest and deepest which could well be imagined, and yet it is during such a transit, at the bidding of one man, eminent in bacteriology, but not in surgery, and still less in hygiene, without any preliminary soundings and without testing the girths, that we are attempting to pass from one animal to the other. If the only result of failure in this case were to be the plunging of the theorist into the water, some views on the subject of baths might undergo modification, which would be all to the good. But it is not the theorist who risks a bath, but the wounded man who risks his limb and

possibly his life by this sudden revolution in surgical practice, and before it is sanctioned and stereotyped the whole matter should be considered, investigated and reported upon. Dr. Shaw-Mackenzie has very clearly stated his objections to Wright's views, and has supported these objections in language which is all the more convincing because of its studious moderation. There is no doubt that he would be able to repeat his experiments and enforce his arguments by further demonstrations before any properly constituted tribunal. Such a tribunal should be appointed without any delay. And it should not be a committee of the British Medical Association.

CURRENT TOPICS.

The Jubilee of Amalgamation.

THE present number of the MEDICAL PRESS AND CIRCULAR forms a landmark in the history of the two journals. Fifty years ago Dr. Jacob, of Dublin, and Dr. Yearsley, of London, men eminent in the profession in their respective spheres, conceived the idea of fusing the two then existing journals, the Medical Press and the Medical Circular into one, under the title of the MEDICAL PRESS AND CIRCULAR. Each continued his own editorial work, the former being assisted by his brilliant son, Dr. Archibald Hamilton Jacob, while the general management of the combined journal was entrusted to Mr. A. A. Tindall. All but the latter, who still comes up smiling in his 75th year, have long since gone over to the majority, but the editorial work is still carried on simultaneously in London and Dublin, and the two divisions of the United Kingdom are represented in editorial, proprietary and office conditions as they were half a century ago. This is probably unique in journalism, and we doubt not our numerous readers will recognise the fact that the paper is as independent and vigorous in its pronouncements, as impartial in its criticism, and as determined in its opposition to shams and abuses within the profession, and in its assertion of the rights and privileges of its members when assailed by interested parties outside its portals, as of yore. If we may venture to accept as a compliment the many letters of appreciation that have reached us of late, and the number of new subscribers who have honoured us with their support for 1916, we may "go on our way rejoicing" in the fervent hope and desire that our readers may experience the really happy New Year for which all are so earnestly longing.

Tuberculosis and Municipal Economy.

THE sudden check in the rising tide of municipal expenditure which the war has imposed will doubtless lead to various drastic changes. Like other cities, Edinburgh has at present to scrutinise ways and means more closely than in the past, and the report by the City Chamberlain on possible reductions in the city's expenditure suggests that the sanatorium treatment of phthisis patients is one of the directions in which thrift may have to be practised. Prior to the introduction of the National Insurance Act the policy of treating advanced,

dangerous cases of phthisis was adopted at an annual cost of about £3,000 per annum. Since the Act was passed the Town Council arranged to give sanatorium treatment to insured persons, and subsequently it extended its hospital accommodation in order to take in all cases whether insured or not. Then it took over the Victoria Hospital and its annexa, and in order to do the whole thing thoroughly became responsible for the treatment of parish cases also. Thus there are now available 231 beds in the fever hospital, and there will be in addition, after the war, 97 at the Victoria Hospital—say 330, with a large dispensary and farm colony as opposed to about 30 a few years ago. The cost now amounts to £19,000 per annum, part of which, of course, is borne by the Insurance Committee and the Treasury. It is not suggested that it will be possible to save any of the expenditure, but the City Chamberlain, acting on the opinion of his expert medical advisers, questions whether it is not to a large extent wasted, keeping in view the object aimed at, namely, the eradication of the disease. Is it not conceivable that in the absence of other preventive methods a large portion of the money spent on sanatorium treatment is simply wasted, and might be better applied in improving housing conditions? And so say many of us. It is one of the most melancholy aspects of the war that a mere fraction of our annual expenditure on destruction would have gone far to settle for ever the housing of the people of these islands.

1916.

THE year of our Lord one thousand nine hundred and fifteen passes, with a high wind crying out of a darkened heaven. But beyond, for the true children of Earth lie the days of crocus and strengthening light. With humanity it is otherwise. From the face of Europe goes up an inarticulate cry of violence of growing intensity with the new year, for the end is not yet; and the lords of life must awhile bring one another to confusion and death. Yet, if the running months reach on to the spring, so also may the new year bring humanity again to the true heritage of peace. The times call for courage, and as much equanimity as can be summoned, not alone upon the battlefield, but at home. Much is heard of the almost unbearable strain upon the combatants, but there is little mention of the inexpressible depression experienced by those not engaged in warfare. The spectre is continually with them; nor have they the same opportunities for forgetfulness as those engaged in the actual prosecution of battle. It is our hope that next January Europe may have outlived her ordeal; that she may come to the realisation of fraternity and forbearance; that the word civilisation may attain to a deeper and a truer significance; that the failing limbs of organised religion may be revitalised by the simple charity of the Son of Man.

The Medical Curriculum.

WE have not been sparing, in time past, of criticism of the medical curriculum as we know it in these countries. We have pointed out its faults both of omission and of commission, and we have hoped for a careful consideration of the whole

problem of medical education. It is a problem, however, which will require careful, deliberate, and courageous consideration. Unfortunately, the changes produced by the war are forcing discussion forward at a singularly inopportune moment. We understand that certain licensing bodies are considering, not so much a reform of the course of study, as some means to circumvent the regulation of the General Medical Council commanding five years' professional study. We sincerely trust that no change may be made at the present. We do not believe in reforms made in haste or in panic, and we believe that few of those whose duty it will be to consider the question can bring a cool mind to the task at present. We admit that there is a possibility of a relative shortage of medical men in a few years' time, but we do not know that the shortage will really be as great as some people think. At any rate, the worst way to meet such a position is to lower the standard of professional efficiency, and almost any change in professional education made at present will be in this direction.

The Insufficient Grant.

MANY hospitals, in receipt of subsidy from the Government authorities, are fast becoming crippled from the financial point of view, while at the same time, being in receipt of Government grants, they do not attract the charitable public. Such endowment, although possibly sufficient at the original period of its allocation, is now very much the reverse, owing alike to the increased expense of an improved *technique*, and to the birth and growth of departments not dreamed of at an earlier date. Originally, the cost of a patient probably approximated nearly to the cost of his keep. In the present day, the calling in of the assistance of the expert specialists, each with his own expensive apparatus, together with the enormous increase in efficiency and expense of a modern operating department, reduces the original stipend to a fleabite. An institution, possibly at one time composed of a few visiting physicians and surgeons, and a much less differentiated nursing staff than at present, must now provide a complete X-ray installation, a complete pathological department, with efficient gynaecological, aural, ophthalmic, and dermatological departments. The inference is obvious. With a grant fixed, say, one hundred years ago, a hospital must either live within its economical limits, and rapidly become obsolete, or forge ahead, maintaining its efficiency while drifting deeper and deeper into debt. The problem is no mere figment, and in some cases it is in need of urgent settlement. Unhappily, no more unfortunate time can be chosen for any financial agitation than the present.

MR. GILBERT BARLING, F.R.C.S., was presented on December 22nd with an illuminated address and portrait on his retirement after 35 years on the staff of Birmingham General Hospital. The portrait shows him in the robes of Vice-Chancellor of Birmingham University.

So far 1,100 undergraduates of the University of Toronto have enlisted for military service.

PERSONAL.

NEW YEAR HONOURS.

In the list of New Year Honours, just published, are the following which are of medical interest:—

Knighthood.—George Andreas Berry, Esq., M.B., LL.D., Lazarus Fletcher, F.R.S., Director of the Natural History Department of the British Museum since 1909; Thomas Wright Parkinson, Esq., M.D., Milsom Rees, Esq., C.V.O., F.R.C.S.

C.M.G.—Surgeon-General Guy Carleton Jones, Director of Medical Services, Canadian Expeditionary Force.

INDIAN LIST.

C.I.E.—John Andrew Turner, Esq., M.D., Executive Health Officer, Bombay Municipality; Suresh Prosad Sarbadhikary, Esq., M.D., medical practitioner, Calcutta; Lieut.-Col. Robert Charles Mac Watt, Indian Medical Service, Chief Medical Officer, Rajputana, and Civil Surgeon, Ajmar.

Knighthood.—Rai Kailash Chandra Basu Bahadur, C.I.E., medical practitioner, Calcutta, and a member of the Municipal Corporation of Calcutta.

VICTORIAN ORDER.

K.C.V.O.—Surgeon-General Sir Anthony Alfred Bowlby, K.C.M.G., F.R.C.S., Surgeon-in-Ordinary to His Majesty.

M.V.O.—John George Griffiths, Esq., Hon. Secretary, King Edward's Hospital Fund for London; Staff-Surgeon Robert Joseph Willan, R.N.V.R. (dated November 10th, 1915).

ORDER OF THE BATH.

C.B.—Military Division: Fleet-Surgeon Arthur Gaskell, R.N. Civil Division: Surgeon-General William Henry Norman, R.N., Temp. Surgeon-General Humphrey Davy Rolleston, M.D., F.R.C.P., R.N.

C.B.—Arthur William James MacFadden, Esq., M.B., Chief Inspector of Foods, Local Government Board.

C.B. (Military Division).—Br.-Col. William Westropp White, Indian Medical Service.

ORDER OF ST. MICHAEL AND ST. GEORGE.

K.C.M.G.—Surgeon-General Sir James Porter, R.N., LL.D., M.D., K.C.B., Honorary Physician to the King; Temporary Surgeon-General Sir William Watson Cheyne, Bart., R.N., M.B., C.B., Honorary Surgeon-in-Ordinary to the King.

DR. A. H. HUCKLE and Dr. C. Christopherson have been appointed Justices of the Peace for the borough of Hastings.

MR. G. M. TREVELYAN, Commandant of the 1st British Ambulance Unit for Italy, has been granted, by the King of Italy, the Silver Medal "For Military Valour."

PROF. F. L. GULLAND, of Edinburgh has resumed his teaching at the University there, on completion of his term of service as Consulting Physician to the troops and hospitals at Malta.

COL. SIR J. ROSE BRADFORD and Capt. H. Morrison Davies are to introduce a discussion on "Gunshot Wounds of the Chest" at a meeting of the Medical Society of London on January 17th.

DR. MALCOLM A. MACDONALD, Surgeon to the Prince of Wales Hospital, Tottenham, who a few months ago was promoted to the rank of captain in the R.A.M.C., has been recommended to receive the French Croix de Guerre (Military Cross) in recognition of his services in attending to the wounded in the firing line in Gallipoli.

CLINICAL LECTURE

ON

PULSATING LIVER.

By LIEUT.-COLONEL SIR ROBERT PHILIP, M.D., F.R.C.P.E.,

Senior Lecturer on Clinical Medicine, University of Edinburgh.

I PROPOSE asking your attention to-day to a subject of considerable clinical interest and rarity—namely, pulsating liver. The affection is, of course, not a primary one, but is referable to precedent circulatory disturbance. The remarkable thing is, that, while the kind of circulatory disturbance which finally leads to its production is common enough, the occurrence of pulsating liver itself is rare.

I am especially anxious to consider with you what are the elements in the circulatory disorder which chiefly contribute to the striking phenomenon in the liver.

In a previous clinical lecture on the subject I had the opportunity of showing the condition in life, and of demonstrating the associated clinical disturbance in relation to the heart and pericardium. To-day, for very sufficient reasons, I propose to approach the subject from the other side, and present to you, first, the organs themselves as removed *post mortem*, and thereafter say something to you as to the clinical phenomena, and finally discuss the bearing of the one on the other. This order has the advantage that you will be able to see for yourselves, severally, the actual anatomical basis on which the clinical phenomena rested.

You will notice especially the large size of the heart—indeed, enormous for a girl of eighteen. The pericardium is completely and firmly adherent to the heart. Notice particularly the relations of the inferior vena cava. The right auricle is much distended, and the commencement of the inferior vena cava still more so. The venous dilatation involves to a remarkable degree the hepatic vein as it joins the vena cava, and the dilatation may be followed as the vein passes into the liver. The liver is much enlarged and presents the aspect of so-called "nutmeg liver" in extreme degree, that is to say, there is evidence of great backward pressure through the hepatic vein. The liver substance is more resistant than usual and the capsule somewhat thickened. Firm, band-like adhesions existed between the anterior surface of the liver and the abdominal wall. You will note on section the increase of fibrous tissue.

If you will keep these points in view, we shall pass to the clinical history of the case.

CLINICAL REPORT.

The patient, æt. 18, a shop-girl, previously a rubber-worker, was admitted to my ward, complaining especially of "swelling of the stomach and breathlessness." These more urgent symptoms had been present for a week or two. The patient had been far from well for some three years.

History.—Three years ago, after a severe wetting, patient got a bad chill, associated with much pain of shoulder-joints and ankles. She was confined to bed for a month, and under treatment, the articular pain passed off quickly. But her condition became aggravated by breathlessness and palpitation, associated latterly with swelling of the legs. The symptoms continuing, she was treated in hospital for three months. She had then two

months' convalescence, and thereafter was able to resume work. During 1½ years, she remained pretty fit. Even then, however, unusual exertion brought on breathlessness and palpitation. This gradually became more marked and her strength began to fail again. She got easily tired, unduly restless, and her appetite was lost. About the same time cough developed with some expectoration, and recurrent pains of a stabbing character. These symptoms becoming aggravated, she was admitted to hospital once more.

At that time she was found to be suffering from valvular disease, especially mitral (both stenosis and regurgitation), and dilatation with some hypertrophy of the heart and pericarditis with adhesions. The most conspicuous and interesting phenomenon was the extreme degree of pulsation of the much enlarged liver. Pulsation, which was general, came and went, never wholly disappearing and becoming much aggravated on exertion or excitement. She remained in the infirmary for some four months, during which time there was recurrent evidence of rheumatic involvement of several joints (knees, elbows, ankles and small joints of fingers).

On discharge she was reported to be both feeling and looking well, with no symptoms of her previous illness, save some breathlessness on exertion. She remained pretty well, doing light work as a shop-girl for another year. Then she began to notice that her clothes were too tight and that her stomach felt swollen. At the same time there was an increase of breathlessness, and cough, with some frothy expectoration, developed. On account of these symptoms she was re-admitted to the Royal Infirmary.

Previous Illnesses.—Of previous illnesses, we may note especially bronchitis as an infant, measles about six years of age, chorea at ten years of age, scarlet fever at twelve years, and pleurisy at sixteen years of age. There was nothing important in the family history so far as could be determined.

General Surroundings and Habits.—The patient worked in a rubber factory, where the air was very close and contaminated with various vapours. In relation to this work she frequently felt giddy and suffered from headache. Subsequent to the second exacerbation, she changed her occupation and became a shop-girl, so as to have better air. Her meals seem to have been good and were taken regularly. She took little tea, no alcohol, and did not smoke.

Condition on Admission.—The patient was of slight figure and poor muscularity. There was a considerable amount of cyanosis, the lips, ears and nails being conspicuously blue. The fingers were not clubbed. The abdomen was evidently distended. There was no œdema of feet or legs. The face was pallid and sallow with a bluish tinge. Dyspnoea was conspicuous. The patient was most comfortable when half-seated, inclining towards the left side. On lying flat the breathlessness was much increased. The temperature was normal.

CIRCULATORY SYSTEM.

Dyspnoea and cyanosis, as already noted, were marked. There was considerable palpitation, becoming aggravated on exertion or excitement, occasional pain over the heart region and slight cough. There was no expectoration. The pulse, 92 per minute, was small and irregular in time and force. The vessel wall was not thickened. The diastolic pressure was conspicuously low.

On inspection, the precordia bulged markedly. There was a diffuse, tumultuous pulsation from base of heart to apex, extending beyond the normal precordial region into the left axilla and epigastric region. The pulsation consisted of a systolic indrawing of the surface, followed by a diastolic rebound. The apical limit of pulsation lay in the 6th interspace in the anterior axillary line, $5\frac{1}{2}$ in. to the left of the mid-sternum. The superficial veins on the right side of the neck and over the epigastric region were somewhat distended and pulsation was sometimes determinable.

Palpation confirmed inspection as regards the form of the precordia and the heaving, tumultuous, diffuse impulse with systolic retraction and diastolic rebound. The ultimate apex beat, as already fixed, was forcible and accompanied by a distinct thrill, presystolic in time. More slight pulsation was determinable to the right of the sternum in the 2nd, 3rd, and 4th interspaces, and slight pulsation also at the root of the neck. In the epigastric region and right hypochondriac region there was pronounced diffuse pulsation. The liver was felt to be much enlarged, and pulsation, which was expansile, seemed chiefly resident in that organ.

Percussion showed a great increase of dullness, the right border of the heart extending 3 in. to the right of mid-sternum, and to the left $5\frac{1}{2}$ in. from mid-sternal line.

Auscultation revealed in the mitral area a loud, blowing murmur, systolic in time, propagated widely towards the axilla and scapula. There was also a pre-systolic murmur. In the aortic area the first sound was roughened, the murmur being propagated only slightly upwards. The second sound was replaced by a blowing murmur, propagated down the sternum. In the pulmonary area an imperfect first sound was heard accompanied by a blowing murmur. The second sound was accentuated. In the tricuspid area the first sound was replaced by a long blowing murmur. The second sound was heard, accompanied by a short, blowing murmur (presumably the aortic murmur referred to).

ALIMENTARY SYSTEM.

The patient's appetite was poor. Apart from this there was little evidence of disturbance or of indigestion in the ordinary sense. The bowels were regular, although diarrhoea had been present previous to admission. There was no jaundice.

The abdomen, as a whole, seemed distended, the swelling being most marked in the hepatic region, where also pulsation was conspicuous.

Palpation showed the liver to be very large, readily outlined, moving freely with respiration, and the seat of extensive expansile pulsation. The lower border in the mammillary line reached to the level of the umbilicus, that is, some 3 in. below the costal margin. The surface was uniform and smooth. There was no tenderness on pressure. In the left hypochondrium the lower border of the spleen was just palpable on full inspiration. A slight degree of fluctuation was determinable in the abdomen generally.

Percussion showed the presence of fluid in the abdominal cavity and increase in the dimensions of the liver and spleen, as already indicated.

Respiratory System.—Apart from the pronounced breathlessness and slight cough already referred to, there were no symptoms. On inspection and palpation the thorax was found to be of poor form with considerable transverse indrawing at the lower part, and some complementary bulging in the upper part anteriorly. Respiratory movements were slight. Some degree of systolic indrawing was determinable on the left side in the 10th and 11th interspaces, posteriorly and laterally. Respirations numbered 24. The chest was poorly clothed, the pectoral muscles and mammae being especially wasted. Myotatic irritability was considerably increased.

Percussion revealed some slight impairment of resonance here and there from apex to base, more particularly on the right side above. Impaired resonance was definite at both bases, especially the left.

On auscultation, respiration was largely masked by accompaniments, both rhonchi and crepitations, coarse and medium, being widely distributed over the chest.

Hæmopoietic System.—Some enlarged glands were traceable in the cervical region but not of any size. The blood showed R.B.C.'s 4,171,600; W.B.C.'s 10,800 per c.mm.; and Hb. 80 per cent.

Genito-Urinary System.—There was little of special note. A trace of albumin was determinable. Amenorrhœa had been present for two years.

Nervous System.—Patient was a poor sleeper and highly sensitive to all stimuli, but nothing specially abnormal was determined.

Tuberculin-Ophthalmic Test.—In view of the history and aspect of the patient, and certain clinical symptoms and signs, the tuberculin-ophthalmic test was practised, with very positive result—viz., pronounced injection and swelling of palpebral conjunctiva and caruncle, with some fibrinous exudate. The reaction was pronounced.

DIAGNOSIS.

The diagnosis I concluded was that she was suffering from endocarditis and adherent pericardium, secondary to rheumatic fever. The endocardial lesion especially involved the mitral valve, giving rise to mitral obstruction and incompetence. As a result of this there was general venous engorgement, as so commonly occurs. The venous engorgement involved all the viscera more or less and was not extreme. There was little œdema of the extremities.

The liver engorgement was so remarkable as to require special consideration. Mere backward pressure was insufficient to explain everything. The size of the liver and the pulsation seemed to imply a condition referable to the hepatic vein, particularly. The presumption, therefore, was that the hepatic vein was, for some reason, specially influenced by the backward pressure, probably in relation to the adherent pericardium.

Beyond all this a tuberculous element was diagnosed—tuberculosis of glands and perhaps tuberculosis of lung and pleura. The possibility of the pericarditis being of tuberculous nature was also discussed.

PROGNOSIS.

The prognosis was necessarily very grave. This was the third recrudescence of symptoms of severe character, following on an endocardial and pericardial lesion of wide extent in a young, delicate girl. The limits of compensation are unfortunately soon reached in the young heart. This is all the more certain when the young patient, thus prejudiced, has to work for her living.

PROGRESS.

The sequel confirmed the view thus forced upon us. The patient's symptoms improved to some extent under the rest and quiet of the hospital with small tonic doses of digitalis and iodide of potassium. She remained fairly well for six weeks, when, unfortunately, she took influenza, which was rather prevalent in the city and in the hospital. Her temperature, which had been continuously normal for weeks, suddenly ran up to 103° , returning to the normal in three or four days. This was followed by a further irregular rise of temperature for about ten days. Thereafter, although the temperature continued normal throughout, her circulation became further embarrassed. The kidney function was interfered with. The amount of water was reduced and more definite albuminuria established. In spite of all we could do, the patient went gradually down-hill and died four months after admission to hospital.

POST-MORTEM EXAMINATION.

I have already referred to the leading features and you have seen the important organs. There was some œdema of the lower extremities reaching in less degree to the loins. The abdomen contained a very large amount of serous fluid, bile-stained.

On removing the anterior wall of the thorax, the heart within the pericardium was seen to occupy a much larger area than normal, extending fully $1\frac{1}{2}$ in. to the right of the sternal margin and more than 1 in. beyond the costo-chondral articulations on the left. The areolar tissue of mediastinum was markedly œdematous. The pericardium was firmly adherent to the heart throughout.

The heart showed much dilatation with some degree of hypertrophy, especially of the right ventricle, and to less degree of the left. The mitral valve presented evidence of old endocarditis with adherence of segments at margin. Some recent vegetations were present near the free margin of the segments. The aortic valve presented slight thickening of cusps and some recent fibrinous deposit. The right auricle was much distended and the inferior vena cava greatly dilated, especially for an inch or two, the dilatation involving to a remarkable extent the hepatic vein. The tricuspid valves were thickened and showed recent fibrinous deposit.

The liver was much enlarged and in an extreme degree of venous congestion and showed a diffuse fibrous change throughout its substance.

The spleen was enlarged and congested. The kidneys presented marked chronic congestion and some recent parenchymatous change.

The left lung showed marked thickening of the pleura over the lower lobe, with a considerable amount of interstitial fibrosis. The upper lobe showed some emphysematous change, and there was some increased toughness of lung tissue, apparently from chronic venous congestion. The right lung presented similar appearances. Towards the apex the pleura was a little thickened and here and there were slight depressed cicatricial areas. In both lungs there was thickening of pulmonary artery, vein and bronchi. Mediastinal glands were œdematous, congested and pigmented.

Gastro-intestinal Tract.—There was evidence of chronic venous hyperœmia throughout.

Mesenteric Glands.—Several glands were somewhat enlarged. One gland was about the size of a cherry, hard and cretaceous.

Microscopic examination showed the pericardial adhesions to be of a fibrous nature. No tubercle was discovered in its layers.

COMMENTARY.

The case presents remarkable features in several directions. The chief interest centres in the rare condition of pulsating liver. As illustration of its comparative infrequency, I may say that during a long term of post-graduate experience, I have only seen it some three or four times. It is to be remembered that we are speaking of true, expansile pulsation, not the pulsation communicated from the aorta, or an abdominal aneurysm to an enlarged liver. Still less should it be confused with the movement communicated to the liver from an enlarged (dilated or hypertrophied) right ventricle. The liver, as a whole, dilates and contracts, the pulsation having been compared to that of an accordion.

The interesting condition is caused by the forcible propulsion of the blood backwards into the hepatic vein during each systole of the heart. The physical conditions which render this possible have been sufficiently shown in the organs which you have seen to-day. The extraordinary dilatation of the hepatic vein, both at its commencement and so far as it is possible to follow the vein into the liver, is very striking. An actual ampulla of considerable dimensions has been created at the expense of the liver substance. The blood, collecting in this great reservoir, separated by no valve from the hepatic venous system, is forced back freely with each beat of the heart. The immediate cause of the clinical phenomenon is thus apparent.

Why pulsation of the liver should occur so comparatively infrequently in relation to tricuspid regurgitation, it is more difficult to say. In most cases of simple, tricuspid regurgitation, dependent on mitral or other lesions, the venous stasis is more general. All the organs participate and dropsy of the extremities is more pronounced. In the present instance the superadded factor of adherent pericarditis played an important part.

Some doubt exists as to why the dilatation is so conspicuous in the case of the hepatic veins. It has been suggested that the inflammatory condition which led to the adherent pericardium extends through the vena cava to the commencement of the hepatic vein and that the inflammatory process lowers the resistance of the venous coats, thus admitting of dilatation in presence of pronounced backward pressure. In the present instance there is, as you may have been able to determine for yourselves, no evidence of such inflammatory extension from the pericardium. The lining membranes of the vena cava and the hepatic veins are more or less thickened, but some degree of this is to be expected in the delicate venous structure as a result of the increased pressure.

How are we, then, to explain the dilatation of the hepatic vein? The adherent pericardium opposes considerable difficulty to the free return of blood into the right auricle during diastole, and the blood accumulates at the outlet of the vein, while during systole, owing to incompetence of the tricuspid, the blood is driven forcibly back into the already distended vein. The upper part of the vein is thus strained during both systole and diastole and yields more and more as the strain is continued. The distension occurs in excess at this part for very much the same reason as aneurysm occurs more frequently at the ascending portion of the arch of the aorta—that is to say, at the point where the strain is greatest. The hepatic veins are involved because of their immediate proximity to the commencement of the vena cava, and doubtless also because the liver tissue is a relatively yielding structure which insufficiently supports the distending vein. Once the dam has been established at the outlet of the hepatic vein it is easy to realise

how, with each systole of the heart, in presence of tricuspid incompetence, there is produced a great backward wave throughout the hepatic venous system which registers itself clinically by the striking phenomenon of pulsating liver.

In addition to the pulsation of the liver, another local manifestation of the hepatic disturbance must be kept in view—namely, the ascites. As we have seen, ascites was a prominent symptom, and much in excess of œdematous manifestations in the extremities. The clinical picture recalls in this way that of cirrhosis of the liver, of which ascites is so conspicuous a feature. In keeping with this, the spleen was enlarged in the given case. Because of this clinical resemblance to true cirrhosis, in the absence of pathological identity, the name "hepatic pseudo-cirrhosis" has been suggested for the condition before us. Because of the association of the adherent pericardium, some have suggested "pericardial pseudo-cirrhosis." It is doubtful whether much is to be gained by the introduction of such names. The condition is essentially the expression of the combination of adherent pericardium with backward pressure from tricuspid regurgitation, associated, it may be, as in the present case, with other valvular lesion or advancing dilatation.

With the further progress of cardiac enfeeblement, more general manifestations of venous stasis presented themselves. During the last few weeks of the patient's life, œdema of the extremities, which was slight at first, became more marked and the other viscera, including the kidney, participated in the general venous engorgement. As the more general effects showed themselves, the pulsation of the liver became less conspicuous. The stasis had become general rather than local.

In addition to this extremely interesting hepatic condition, the case before us affords a remarkable illustration of the grave consequences which may accrue from rheumatic fever, more particularly in the young subject. It affords a cogent lesson as to the need for care in the prophylactic and curative treatment of all rheumatic manifestations. There is considerable risk that some of the slighter manifestations of rheumatism are too lightly dealt with, and thereby cardiac disturbance permitted which may never be rectified. I would counsel you in the strongest way to give careful heed to the slightest indication of rheumatism in the growing subject.

There is a further aspect of the case of immense significance—namely, the concomitance within the same individual of two distinct toxic influences. Along with the rheumatic element which was so distinctly registered, both clinically and pathologically, there was also present tuberculosis.

The aspect of the patient, the evidence of some slightly enlarged glands in the cervical region, and certain physical signs in the chest raised the suspicion, and indeed seemed to justify the diagnosis. The view was corroborated by the positive reaction afforded by the tuberculin-ophthalmic test, and was subsequently conclusively confirmed by the determination *post mortem* of several enlarged glands, more particularly the marble-like cretaceous mesenteric gland which you have had an opportunity of seeing. In keeping with this is the thickening of the left pleura, and the presence of interstitial change, more particularly in the left lung, and the delicate, depressed scars to which I have referred at the right apex.

You recall how in the history there is the record of pleurisy when the patient was sixteen. How natural it might seem to assume that the pleurisy thus occurring in conjunction with the rheumatic manifestations was likewise rheumatic in origin. None the less, both clinical experience and pathological results show that this was probably not the

case. It is another telling illustration of what I believe to be one of the most important facts in clinical medicine—namely, that a pronounced pleurisy is in the vast majority of cases of tuberculous origin, and is seldom purely rheumatic in nature.

Conversely, the pericardium, as you know, is frequently involved in relation to rheumatism. Both endocardium and pericardium are thus frequently involved. The pericardium is less frequently affected by tubercle, although cases of the kind do occur. The possibility of the adherent pericardium being of tuberculous nature was discussed at our clinique on the patient during life. The greater probability in favour of its rheumatic origin was accepted. Careful histological examination *post mortem* has failed to determine the presence of tubercle in the pericardial structures.

NOTE.—A *Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Albert Mouchet, M.D., Surgeon to the Paris Hospitals, Chief Surgeon to the Auxiliary Hospital No. 26, at Orleans. Subject: "Chronic Recurrent Tetanus."*

ORIGINAL PAPERS.

THE USE OF LUTEUM EXTRACT IN THE TREATMENT OF MENSTRUAL DISORDERS.*

By ADAM P. LEIGHTON, JR., M.D.,
L.M.DUBLIN.

WHEN one essays to present a dissertation, no matter how brief, on the topic of corpus luteum therapy, it is at least assumed that he possesses some special knowledge of the subject, which, in all probability, is the result of extensive observation or investigation. In this instance, however, such is not the case. I have incorporated herewith little of scientific value or true originality.

A discussion of the time-worn text-book subjects of amenorrhœa, dysmenorrhœa, and other phases of altered menstrual flow, and a consideration of the relation of these symptoms to certain underlying pelvic or constitutional conditions, would be decidedly boresome, hence it is my intention only to offer, in an epitomised form, a few case histories embracing the result of personal experience with the use of luteum extract, combined with a small amount of comment as to the indications for its administration and the limits of its action.

To the corpus luteum is attributed a twofold action: First, of preventing the formation of an excess of scar tissue in the ovary, following follicular rupture and ovular expulsion; and, second, of subsequently elaborating an internal secretion.

As a result of an extensive series of experiments, it has become a well established fact that this internal secretion exercises an important influence upon the sexual cycle, such as causing the phenomenon of menstruation, controlling the nutrition of the uterus and, if pregnancy occurs, probably aiding in the attachment of the ovum to the wall of the uterus by causing the endometrial changes which characterise the decidua. It seems also to influence the physical development of the woman and bears a distinct relationship to the other body glands of internal secretion, thereby aiding in the maintenance of normal metabolism.

Some years ago, acting upon the assumption that the ovary harboured this action, an immense

* Read at the twenty-eighth annual meeting of the American Association of Obstetricians and Gynecologists at Pittsburg, September, 1915.

amount of interest was taken in the possibility of successfully treating with ovarian extract certain gynaecologic disorders which could be theoretically attributed to hyposecretion of this organ. Little benefit was gained, however, in these cases for the obvious reason that we now know that the ovary, as a whole, did not furnish this active principle.

Following the valuable demonstration of Fraenkel and Loeb, enhanced by the reports from such men as Burnam, Kelly, McDonald, and others, the corpus luteum extract supplanted the ovarian extract in therapeutic use and now we are well agreed as to its efficacy where there are certain given indications.

Its chief field of usefulness seems to be, (1) in the treatment of functional amenorrhœa, (2) the neuroses of the natural, artificial and premature menopause and (3) in those cases which come under the head of the so-called "ovarian deficiency" type, occurring during menstrual life.

In this last class, dysmenorrhœa should be especially included. In my own private practice I have observed, in a truly extraordinary manner, the cure or relief of many such cases through the medium of this type of organotherapy. My best results, however, have been gained in the administration of corpus luteum for the relief of the severe nervous symptoms attendant upon the menopause of both the physiological and artificial varieties and the functional amenorrhœa of young women.

As illustrative of the action of corpus luteum in functional amenorrhœa, I have two cases of interest which I should like to describe briefly. The first case is that of a young school girl, aged fifteen, who consulted me in November, 1914. She had first menstruated two years before this time. Six months had elapsed before the next period appeared. She menstruated but three times in the following year and when I first saw her, the history given was of amenorrhœa for a period of nearly four months. Her weight was 196 pounds, and she had gained in weight rapidly during this time. She was very nervous, irritable, and depressed. She had given up school because "it worried her so much." The appetite was good, but she complained of much disturbance of digestion. I commenced treatment by giving her luteum in the dose of 10 grains, three times a day. Three weeks later she menstruated normally. At this time I added thyroid extract in the dosage of five 2-grain tablets a day. She has continued the use of these two extracts up to the present time, with but one short intermission and a slight decrease in the dosage of the luteum extract. When last seen, on the second of this month, after having returned from a stay in the country for the summer, she weighed 167 pounds, a loss of 29 pounds, and has menstruated regularly every five weeks since the treatment was begun. There is absolute cessation of the nervous and digestive symptoms.

The next case is of a similar nature. A young married woman, aged nineteen, consulted me concerning arrangements for her confinement which she anticipated in another month's time. She gave a history of amenorrhœa for eight months; during this time she was "sure she felt the motion of the child." On casual inspection she certainly looked the part of a pregnant woman; but upon examination she was found to possess a small infantile uterus and a hypoplastic condition of the genitals. An enormous deposition of fat was evident, especially on the abdomen and in the breasts. The hæmoglobin was about 70 per cent. She was drowsy, asthenic, at times exceedingly nervous, and has experienced violent attacks of tachycardia on several occasions. Bland's mass by mouth and iron citrate by injection, plus corpus luteum (30

grains a day) was prescribed. Her general and nervous condition gradually improved and menstruation appeared shortly thereafter. I saw this patient regularly for four months. During this period she menstruated four times with fairly normal intervals. I have had no opportunity to see her since.

In these two cases we have conditions of distinct similarity. While it is evident and granted that there was ovarian insufficiency present in both instances, one must consider diminished pituitary function in the second. Here were present the various symptoms which would point to probable hypopituitarism with the resulting progressive general obesity associated with atrophic changes in the genitalia. No doubt, too, there was abnormal secretion of the thyroid which would explain the nervous symptoms. As Bandler states it, "if there is a diminution of the ovarian and thyroid activity and the ovarian activity is so diminished that a relative degree of thyroid hypersecretion exists, we have, in addition to the increase in weight, an excitable condition due to this thyroid hypersecretion."

There is no doubt that some cases of obesity with amenorrhœa are due to ovarian inactivity; some are due to diminished thyroid function; many are of the so-called hypophysis type and, in all probability, many are due to an involvement which includes failure of function in more than one of these glands; as is illustrated in the cases just mentioned.

In the neuroses of the surgical and natural menopause, as I have said before, the corpus luteum therapy plays a most important part. The nervous, digestive and circulatory disturbances of the climacteric may be frequently controlled by its use. Likewise its efficiency in controlling similar symptoms, following hysterectomy and oophorectomy, has been repeatedly demonstrated. I consider it a necessary adjunct to the treatment of such cases.

Two years ago I removed the right tube and ovary from a woman in whom a ruptured tubal pregnancy on the opposite side had occurred a year and a half previously and at which time a salpingectomy and oophorectomy was done on the left side. Shortly after my operation she experienced all the extreme and disagreeable symptoms of the climacteric to such an intense degree that her work, as a dressmaker, was greatly interfered with. No relief was obtained until she began the use of corpus luteum. Thirty grains a day soon brought about complete cessation of the symptoms. She still continues the use of the product in decreased dosage and can dispense with its ingestion for considerable intervals of time without experiencing any immediate return of discomfort.

In the treatment of those patients who, during their menstrual life, show severe nervous phenomena such as irritability, malaise and depression, accompanied by headache and scanty menstruation, corpus luteum is obviously indicated. It is really astonishing to see how quickly there is a change for the better. (How often, too, do we see patients who suffer with dysmenorrhœa, presenting this same train of symptoms, indicative of insufficient ovarian function.

This brings me to the subject of dysmenorrhœa. I do want to make mention of my small experience with this condition in relation to my experience with corpus luteum extract as the remedial agent. The results gained by corpus luteum therapy, as applied to dysmenorrhœa, have been far from remarkable, although the reports of some observers show its undisputed value, when utilised in those cases where functional ovarian deficiency is present. I have used it with varied results, but the recital of two

cases of dysmenorrhœa, in which absolute relief was obtained through its use, should have some weight in the consideration of this subject.

The first case was that of a married woman, æt. thirty-two, who had suffered intense pain at her periods ever since menstruation made its appearance. She had never been pregnant. The flow was normal in amount and occurred at regular intervals. I used every method known to me to relieve the condition. I confess that I often resorted to morphine. She experienced this pain only on the first day of the flow. She had an acutely anteflexed uterus with apparent cervical stenosis. I performed a dilatation and posterior division of the cervix, but no relief followed. I tried corpus luteum, giving her one 5-grain tablet three times a day; increasing to two 5-grain tablets three times a day, a week or ten days preceding the period. At first no appreciable relief was observed, but, subsequently, she menstruated almost painlessly. This was in the spring of 1913. I have since received word from this patient, stating that she still uses corpus luteum tablets, and that she has no pain at the time of menstruation. Relief after seventeen years' suffering!

I have a parallel case in a woman, æt. thirty, a semi-invalid, who is thin and poorly nourished. Her menstruation was regular but scanty, and she had always suffered much pain on the first day of menstruation. The pelvic organs are seemingly normal. Fifteen to thirty grains of lutein extract a day has relieved the pain almost entirely, increased the flow and bettered her general condition. These are but two of a dozen such cases which I have in mind, but they are sufficient to illustrate my point.

The fact that dysmenorrhœa is oftentimes amenable to this therapy allows for some interesting theorisation as to its exact mode of action. The ovarian secretion is responsible for menstruation. That is a well-proven fact. We also know that the result of this action is a periodic hyperæmia of the uterus, and thickening of the endometrium followed by diapedesis of erythrocytes, rupture of dilated capillaries and the formation of small hæmatomata; this is again followed by rupture of the subepithelial hæmatomata and exfoliation of small portions of the uterine mucosa. Yet this description does not fully cover the action of the ovarian internal secretion. To illustrate, let us take an analogy from the alimentary system. Inasmuch as we know that the hormone of the duodenum, called secretin, passes through the blood stream to the pancreas and there stimulates the acinar cells to pour out their enzymes, so it is quite possible to believe that the ovarian secretion acts as a hormone in the uterus. In addition to acting as a vasodilator of the uterine capillaries, it has perhaps a further selective action in exciting or stimulating an intracellular or autolytic enzyme in the endometrium, which so softens and digests the histological elements of this tissue that the physiological phenomena, previously described (namely, diapedesis, rupture of hæmatomata and exfoliation of mucous membrane) are made possible and easy, thereby constituting normal menstruation.

Such a theory as this furnishes for me an attractive explanation of some cases of dysmenorrhœa of the so-called congestive or membranous type; for, where the ovarian hormone is altered or lessened, it may fail to excite in sufficient amount the uterine autolytic enzyme with the result that the endometrium, lacking its proper preparation and softening, acts as a barrier to an easy escape of blood; the congested membrane either remains to form a foreign body and set up uterine spasm, or becomes detached in the comparatively large portions that are characteristic of membranous dys-

menorrhœa. For this reason. I put forward the suggestion that the cases most suitable for the administration of corpus luteum are those which are characterised by excessive first-day pain, with scanty discharge, suggestive of an intense unrelieved congestion, usually followed later by a free flow and immediate relief of pain.

From my little experience, I am certain that there are cases of dysmenorrhœa in which the main causal factor is deficient action of the natural corpus luteum. I am not carried away with the idea that the therapy of corpus luteum is a "cure-all" in any sense of the word; on the other hand, the cases which may be traced to ovarian deficiency are probably in the distinct minority. One must not allow himself to be so impressed with the ætiological value of some one factor in the cause of disease, that he forgets, or becomes indifferent, to other factors of equal importance.

Surgery is necessarily indicated in those cases where we find pelvic pathological conditions or anatomical abnormalities, which we are wont to consider as the probable causes of dysmenorrhœa. Too often, however, do we resort to operation and, consequently, too often are we disappointed in the results, because the defect is not surgical but glandular. Again more often than one would think, is organotherapy indicated in conjunction with surgical intervention.

There are some serious drawbacks to the use of corpus luteum. It generally has to be used as a routine or continuously to obtain and to maintain results. Its cost hinders its more frequent administration. Its action is not immediate, it is cumulative; for that reason patients, and we ourselves, too often discard its use after a short trial, if it has been unproductive of good results.

As regards its dosage, I find that from 15 to 30 grains a day, seldom more, is sufficient in any case. Its prolonged administration has not brought about any untoward symptoms in my cases; with, perhaps, the possible exception of slight gastric disturbance in one or two instances.

The subject of organotherapy, in its present experimental state, is rather involved and indefinite, and while it is sometimes difficult to recognise and identify the cases which would be benefited by corpus luteum, yet when there is a possibility of "ovarian deficiency" being an ætiological factor in any gynæcological disorder, we owe it to the patient to make use of this remedial agency, for its value is well determined.

THE AMBULANT TREATMENT OF VARICOSE VEINS.

By DOUGLAS H. STEWART, M.D., F.A.C.S.,
New York.

THIS preliminary report may appeal to two classes of readers, viz., the men who always operate and those who never do. The former knows only too well that baffling adverse conditions sometimes ensure failure by such a complete victory over care and skill, that the cases that once gave the fairest sort of advance promises, may belie them in every detail after a lapse of two years. Herein is suggested the possibilities of an after-treatment which will enable one to control emergencies, to correct the beginnings of a post-operative deficiency, to "about face" a progressively poor result, and to convert a threatening disappointment into a happy outcome. Non-operative treatment is successful if it yields a temporary amelioration of annoying symptoms, yet the addition of the aforesaid method may so reinforce it that failure is inconceivable; inasmuch as the non-success of a first injection may be replaced by the fortunate termination of a second or other

attack. In other words, the method may aid a previous operation or may forestall and render unnecessary a proposed radical one, but it will not produce a fault in any after-coming surgical interference.

The literature of intravenous curative injections is prolix and accessible.

Quotations are omitted largely because the writer is such an admirer of the "blue pencil" that he has acquired a habit of skipping medical articles that are overburdened with history. The older methods gave good results in from 70 to 75 per cent. of the patients treated; but from seven to fourteen days in bed was an essential demand. The enlarged, elongated and superficial veins between the knee and the ankle produce changes in the skin, inflammation, and pain, and most severely handicap their owner in his daily labours. These may be cured without absence from business, loss of time in bed, or loss of the services of a hospital bed. The field may be small, but it is neither trifling nor unimportant. The statistician may estimate for himself the loss, in dollars and services, entailed upon our city by labourers, housewives, and shopgirls who are dragging around the ball and chain conditions entailed by diseased veins and their sequelæ. It would, however, take a brilliant political economist to put the facts more forcibly than one poor old coloured woman did, at my clinic. She said: "I went from hospital to hospital for ten years, and once in a while I could do a week's work, and then everything began all over again and slowed me down so that I couldn't move fast enough to cook for the men. I worked round racing stables, where a thousand dollar horse with one bad leg was worth five dollars for his hide and five for his meat to feed the lions in the circus. But my hide had a big hole in it (the ulcer), and I used to wish the law would let my husband sell my carcass for lion's food and end it all. But all I was good for, to anybody, was just something to swear at." She now earns 30 dols. and her expenses per month, with steady employment. Rather a decided difference in one person's share of the "world's work."

Acetic acid will close a vein promptly, but its injection is very painful for from two to five minutes. The vein may die and slough out, but this is really not an alarming matter. The blood vessel is destroyed, that is all, and the end sought for is accomplished, but not in the easiest way.

Shuford's solution has been widely used for years to destroy and remove piles. The idea is not so much to form a blood clot as to produce an adhesion of the wall of the cavity into which it is injected. Perhaps the term soft desiccation describes the process, but slough does not.

Consequently the injection of 5 minims or less of the aforesaid solution, followed immediately by the application of a pressure pad, which forces the walls of the veins in contact, should convert that contact into an adhesion if the pad is held firmly in place, for a week, by a strap of adhesive plaster. Finally, leg, pad and all should be snugly bandaged with one of those webbing affairs and the patient instructed in its application and removal. The pad and adhesive plaster are never to be disturbed by the patient under any circumstances, nor the site of the injection uncovered.

Shuford's solution is borax, acid salicyl. aa. dr. i., acid carbol. dr. iii., glycerin ad. oz. i. The *technique* of its use, while simple, requires such close attention to the minutest detail that it is best to devote another paper solely to that subject. He who interferes with the usual progress of varicose veins, from bad to worse, may be said to be playing with fire and gunpowder; but the writer has a *technique* which, after much experience, has done good work without at the same time giving rise to anxiety.

CERTAIN UNCLASSIFIED FEVERS : THE TYPHACEÆ (TYPHOID GROUP) AND ENTERICOID OR PARA- ENTERIC FEVER.

BY RICHARD STEIN, M.D.

Visiting Physician to the Lebanon Hospital, New York.

By unclassified fevers I understand certain forms of infectious fevers which, though frequently met with, and, in part, at least, well known to clinicians in a general way, have not as yet been definitely named. This is due to the fact that often they are passed over as unimportant, and have therefore not been subjected to an exhaustive bacteriological study. Perhaps the main reason why they have not been differentiated is that our present methods of investigation—bacteriological, chemical and otherwise—are not far enough advanced to enable us to classify these fevers nosologically.

The fevers under discussion are primarily caused by infective agents, as distinguished from those fevers which are due to disturbances of the function or of metabolism. This latter group may be designated as the fevers of endogenous origin. Menstrual fever may be cited as an example of this type.*

The fevers under discussion are also distinct from the fevers of exogenic, chemical origin. Finkelstein's resorption fever after sugar installation in infants is an example of this type. What is generally called gastro-intestinal auto-intoxication is a chapter by itself, the import of which is still *sub judice*. If auto-intoxication causes fever at all it is, in a given case, very difficult to state what part, or how much of the fever, is due to the absorption of the toxic products from the surface of the gastro-intestinal tract, and how much is due to the accompanying bacteræmia. What is now popularly called ptomaine poisoning comes under this heading. It is probably nothing more than a gastro-enteritis of bacterial origin. The fevers caused by group A of the paratyphoid bacilli are often accompanied by an acute gastro-enteritis. This is one form of paratyphoid A infection. Both paratyphoid A and B infections, however, may present the complete clinical pictures of typhoid fever. The enteritis of the first form is the result of surface infection. The typhoidal symptoms of the second form are the result of blood-invasion of the paratyphoid bacilli.

Out of a large number of unclassified fevers, I will confine my remarks to a number of those which resemble typhoid fever. Since I have begun to study these cases my attention is not infrequently directed in hospital service toward a form of fever which is brought in because the patient arouses the suspicion of having a typhoid infection. These cases have the general clinical aspect of that disease. In their future course, they may or may not develop into a genuine case of typhoid fever, as the saying goes. More often, they defervesce in a week or ten days. I am not inclined to think that these cases are abortive cases of typhoid fever. In private practice the occurrence of these typhoid-like fevers is a source of anxiety to the family. A positive answer as to the nature of the illness which is demanded for hygienic and prognostic reasons can often not be given.

* *American Medical Journal*, October, 1915.

The course of this fever resembles that of a mild infection; it comes nearer to the descending curve of the third week of a mild typhoid fever than anything else. Blood cultures are negative. The blood count shows leucopenia or moderate leucocytosis. Eosinophiles are often absent. Relative lymphocytosis may be present or absent. There is no predominating symptom present, pointing to any of the organs. Persistent search for catarrhal symptoms in the respiratory organs is mostly fruitless. In the lack of symptoms—intestinal, respiratory, and otherwise—in the general prostration, the marked enlargement of the spleen—I have palpated the spleen in several instances—in the configuration of the fever curve these fevers strikingly resemble a mild or abortive case of typhoid fever. It must be admitted that these fevers are possibly cases of so-called auto-intoxication. Still, it is difficult to prove them as such, as the decomposition products in the urine, in the shape of the aromatic bodies, scatol, phenol, and indol, are missing.

Judging by analogy, we are dealing here with a mild bacteræmia not unlike a typhoid infection. The infective agent in all probability enters the blood through the portals of the respiratory or intestinal lymphatic system. This can only be proved by positive blood cultures which, so far, have not been realised.

Those of us who practised during the great influenza pandemics of the late eighties and early nineties observed cases of group-infections of influenza in families, some of which strikingly resembled typhoid fever. Since that time I observe every year a number of cases of fever, typhoid-like in character, which go under the name of influenza, but which are not caused by the influenza bacillus of Pfeiffer, as proved by negative sputum culture, in appropriate media, but are due to infection with pneu-mococci or streptococci. These fevers may start in with catarrhal respiratory signs. If they do not, they are often unmasked late in the disease by resolving into a predominant general bronchitis.

In an interesting contribution by Dr. David Riesman, of Philadelphia, discussed by Dr. Hobart Amory Hare, (1) it is proposed to call the fevers allied to the typhoid fevers, entericoid fevers, febris entericoides. I have called them typhocoid or paraenteric fevers. Presumably these fevers are caused by the bacteria closely allied to the bacillus of Eberth. Since Schottmüller's description of the paratyphoid groups A and B, a dozen or more observers have added distinct varieties of this group which are known by the names of the discoverers. Typhoid-like fevers may also be caused by the paracolonic bacilli. Warren Coleman (2) described a case clinically identical with typhoid fever, inclusive of rose spots, caused by a colon bacillus. Schottmüller (3) recently described an epidemic of herpetic fever in women, which was associated with urinary symptoms. The pus in the (oral) labial herpes contained a pure culture of a colon bacillus.

Some one has said that Escherich's discovery of the colon bacillus was hailed as an unwelcome event in bacteriology, as innumerable questions, serological and otherwise, were raised by the seemingly inexhaustible number of strains of the colon bacillus. The answers to most of these questions have so far been unsatisfactory; es-

pecially has this been so as regards the subject under discussion. Perhaps some day will be written the biological history of the ascendancy of the colon bacillus into the fixed types of the various forms of typhoid fever.

It might not unjustly be said that the foregoing observations on the interpretation of these unclassified fevers have, after all, only a theoretical or at most a purely scientific significance, were it not for the fact that in a number of instances I have seen mild fevers of this kind, after a short subsidence, merge into severe cases of typhoid fever. Now there can be no doubt that in these instances these initial febrile movements which are seemingly identical with the entericoid or para-enteric fevers described above, constitute the introductory stage of true typhoid fever. We must assume that after the usual low temperature fluctuations of the incubation stage of typhoid fever is passed, there is a preliminary or initial fever, in these cases of typhoid fever of a week's, ten days', or fortnight's duration. Sometimes this initial fever is apparently nothing else than a primary access in irregular, atypical forms of typhoid fever. The complete *ensemble* of the case then shows a series of such accesses with remissions. It lies in the nature of the case that the initial stages of typhoid fever have not been subjected to the careful observations of the later stages. In the large number of cases, at least in hospital practice, the patient does not come under observation before the second or third week of the fever, or even later. I have at present a case under observation which presents this initial stage. At that time the patient showed a large spleen with a mild febrile movement. Diazo reaction negative. After a short remission, rapid rise of temperature, spleen larger, diazo strongly positive, blood-culture negative. Numerous rose spots, moderate leucocytosis, eosinophiles constantly present. Widal reaction, taken every few days, absolutely negative. In the sixth week, Widal positive, 1 to 20. It has been negative ever since. Reaction against all available paratyphoid strains negative. Culture of urine and faeces negative. Complement-fixation for typhoid fever negative. The steady increase in hæmoglobin and eosinophiles and the slow but certain reduction in the size of the spleen in this, the eighth week, seems to prove that complete convalescence has already set in.

From what has been stated it becomes evident that the fevers under discussion will bear close study. In a given case, the question to be decided is, Am I dealing with a case of typhoid fever or not? This is often decided soon enough, when unmistakable clinical evidence is present. The laboratory corroborates the diagnosis sooner or later. If the diagnosis of typhoid fever cannot definitely be made, the situation is a puzzling one. We have seen that there is a class of fevers, clinically resembling typhoid fever, which at present it is hard to classify, and to give a distinctive name. No doubt we are dealing with infections of various kinds. Their true nature will not be determined until they are subjected to an exhaustive biological research.

Furthermore, there is a class of fevers which clinically are unmistakably typhoid fevers, but in which, also, the laboratory proof is inadequate. This opens up the large question of the biology of the typhaceæ. This name has been used by

Loeffler (4) to designate the colon, paracolony, paratyphoid, and typhoid groups of bacteria. The same name, I think, may also be used as a collective appellation for the various groups of fevers caused by these typhoidogenic bacteria. Typhoid fever, a clinical entity, is produced by a variety of infective agents. Some of these have been determined; their biological reactions are well known. Others are still to be isolated. A comprehensive study of the bacteriological relationships of the typhaceæ fevers among themselves, the determination of the appropriate culture media for each variety of bacteria, the amplification of our knowledge of agglutination, complement-fixation, opsonic index and other biological reactions will serve to classify the individual case in the clinic.

For valuable assistance in the laboratory I am indebted to Drs. Hensel and Garbat.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our correspondents.]

QUACKERY AND THE ETHICS OF JOURNALISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The system of getting money under false pretences without consideration of the misery which this must involve, and the connivance of owners of great newspapers with this system, seem to me merely manifestations of that debased form of neo-commercialism which imbues so large a section of the world of business. To get money without honestly working for it and to spend it on degrading luxury seem still to form the ideal of many so-called business men. To those men participation in crime for gain is quite laudable, and even to compass a felony is quite legitimate if the stakes are large enough to make it worth while. A truly cunning felony up to date need not land one in a criminal court. It need not lead to punishment—the only thing that can bring shame. If, when arraigned, you can show a flaw in the indictment, or if, after conviction, you can get the sentence quashed on appeal, you may gain—if you have secured the wealth—the admiration of that section to the community who would be willing to follow your example. If you have played the game with astuteness your wealth will give you unlimited power. You may in due course buy for yourself, and not very indirectly, any title you please from a knighthood to a peerage. You may pose as a philanthropist, and take part in moulding national institutions and shaping the destinies of your country. There are plenty of people of this type about; they set a sinister example to men whose moral obliquity needs very little to develop it into criminality. The war is causing all that is best among our people to pass through the cleansing fires of suffering and adversity. The hope must be that on the advent of peace the majority of our citizens will set to work to cleanse their dwelling place of the swarms of vermin and parasites which now infest it. That the people will learn that happiness and peace of mind are not to be got from the pursuit of pleasure and vulgar

luxury. They will aim at developing a merry England, but they will strive after creation of merriment which shall come from the heart and not from the teeth outwards. The majority of citizens must be permeated by high ethical ideas, and not be content whilst there exists needless suffering due to man's inhumanity to man. Meanwhile, I feel that the MEDICAL PRESS AND CIRCULAR, although it is probably read by no large a section of the public, is doing a real service by keeping the quackery question to the front. I share with your correspondents their indignation at the persistent misconduct of newspapers with regard to it. My work obliges me to take several leading papers daily. I have been amazed to see the quality of some of the huge advertisements displayed in their pages since the Report of the Select Committee on Patent Medicines, which did away—as is pointed out in your paper—with any excuse for ignorance. You have also pointed out that the Committee strongly urged that not only the sale, but the advertising of a long list of secret remedies should be at once prevented by law. In this list were cures for consumption, and yet in one of the foremost papers of the day now before me there appears a huge advertisement of one of these cures. This one advertisement may have cost anything from £25 to £100. It is no doubt appearing in many papers and catching many victims. The analysis of this precious compound is furnished in official publications with which every newspaper manager is well acquainted. It needs no medical knowledge whatever to recognise the worthlessness of this concoction for any of the purposes for which it is recommended.

I am, Sir, yours truly,
A STUDENT OF SOCIOLOGY.

December 31st, 1915.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent Mr. Sewill is probably right when he suggests that lower-class newspapers take their cue from the higher; but from whom do the higher-class papers take their cue? To me it would seem to be from some of the medical journals. I have just thrown into the waste-paper basket an attractive medical periodical to which I cannot subscribe, although invited, because it contains numerous quack advertisements. I have just returned from a visit to the library of an institution which receives most of the medical journals. Out of nine of these, including hospital journals, seven—among them being one leading weekly—contain advertisements to which an adjective much stronger than quack might be justly affixed. Quis custodiet ipsos custodes?

I am, Sir, yours truly,
ANTI-CANT.

January 1st, 1916.

WHO MADE THEE A RULER?

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—At this critical moment your significant proposals for the smoothness and efficiency of a medical Central War Committee must of necessity evoke the most serious and earnest consideration of the community. As you truly insist, the body so intrusted must be of a national and authoritative character, representative of the medical profession, influential, and acceptable to all concerned, and as far as possible inspiring the confidence, respect and obedience of its constituents.

The issue before us is, apparently, as follows:—

- (1) Whether the Government should requisition the services of the General Medical Council.
- (2) Whether the Government should create a Central War Committee *de novo*.

(3) Whether support can reasonably and properly be accorded to the self-constituted committee of the British Medical Association, on terms and conditions to be decided upon.

As against the General Medical Council it is urged that they have no organisation suitable *ad hoc*, that only four or five members live in London, and that therefore they could not manage an institution requiring constant supervision.

It is, however, worthy of mention that they have the great advantage of a charter and of powers to act upon for the purposes of organisation, etc., and that the accessibility to London is easy and leaves nothing to be desired. But the difficulties, if any, of travelling must also apply to the Council of the British Medical Association. The General Medical Council have earned the good will, the respect and loyalty of the medical profession, and may rely upon Government support.

The British Medical Association has of late had most ample opportunities of showing its methods, its work and its diplomatic power, and as the outcome has become a discredited body, with, for the time being, "Ichabod" branded upon its portals, and it is doubtful whether its members will tolerate any attempt at rehabilitation at the expense of their funds. Indeed, the Council must be prepared to be surcharged with these extraneous expenses, however zealous their activities may sound. It is registered under the Companies Act, and in the light of the abortive attempt it made a few years ago to obtain a charter, it is not likely to try its luck again before the end of the war.

The British Medical Association is stated to have co-opted representatives of the Royal College of Physicians and the Royal College of Surgeons and the Universities of Oxford, Cambridge and London, but it is not clear what power, either singly or collectively, these members will have, or whether the control will be vested in the Executive of the British Medical Association.

Nothing could be more deplorable at this present crisis than a renewal of the dissensions in the ranks of the medical profession, and for which the British Medical Association has been largely responsible.

I am, Sir, yours truly,

DENNIS VINRACE.

Gower Street, London, W.C.

January 1st, 1916.

SPECIAL CORRESPONDENCE.

FROM OUR OWN CORRESPONDENTS.

SCOTLAND.

SCOTTISH WOMEN DOCTORS IN SERBIA.

A LETTER has now been received from Dr. Elsie Inglis, dated November 5th, telling of the adventures of the Scottish Women's Hospitals which were sent to Serbia earlier in the year. The first hospital to be evacuated as the result of the Serbian retreat was Dr. Macgregor's, which was transferred from Mladanavatz, immediately after the fall of Belgrade, to Kraguievatz, where they organised a huge dressing station and treated over 5,000 cases in a week. Then Kraguievatz also had to be evacuated. Next Dr. Alice Hutchison's hospital had to be moved to Poshega, and when the Austrians crossed the western frontier to Vrenaskavania further east, where she and Dr. and Mrs. Hope have now a small hospital and dressing station. The third of the northern hospitals, at Lavaravatz, was the last to be moved, to Krushenyvatz, whence Dr. Inglis's letter is dated. It is not very easy to follow the further movements of the various hospitals and field ambulances, but it is clear from what Dr.

Inglis says that she and her co-workers have resolved to stick to their posts and do what they can to alleviate the sufferings of the Serbs. At the time of writing the intention apparently was to concentrate the various units at Novi-Vazar, and thence cross into Montenegro. Dr. Alice Hutchison, who is in charge of one of the hospitals, was, it may be remarked, in charge of a hospital in Bulgaria during the recent Balkan war.

EDINBURGH ROYAL INFIRMARY.

From a short report by Dr. W. B. Blackie on the finances of the Infirmary, the Institution appears to be weathering the difficulties of the present financial situation. Two years ago the managers urged that as it was unlikely that the large legacies they had been accustomed to would continue, an endeavour should be made to raise the ordinary (subscription) income by £10,000, and this year this has been done. During the year 13,102 in-patients have been treated, the daily average being 903. The ordinary income was £46,474, an increase of £10,142, and among incidental donations may be noted the sum of £3,686 resulting from a "flag day." The ordinary expenditure was £60,944, showing a deficit of £14,470, which is better than last year by £9,687. The cost per bed has fallen from £71 to £68. During the year 200 beds have been set apart for naval and military cases, who have been treated free, but in future the Government is to pay for them at the rate of 4s. a day.

SPECIAL REPORTS.

COST OF A PANEL DOCTOR'S PRESCRIPTIONS.

In the King's Bench Division of the High Court of Justice, on 19th December, Mr. Justice Rowlatt delivered a judgment in the case of O'Neill v. County of Middlesex Insurance Committee, which is so important to the profession that we reproduce it here:—

In this action Dr. Bernard O'Neill, who practised at 9, Duke's-avenue, Chiswick, sought an injunction against the Middlesex Insurance Committee to restrain them from surcharging him with £323, or from deducting that sum from the amount payable to him by the defendants under the National Insurance Acts. He also asked for a declaration that the defendants were not entitled so to surcharge him, and that Regulations 40 and 51 of the National Health Insurance (Medical Benefit) Regulations (England) were illegal and *ultra vires*, and of no force and effect.

Mr. Rigby Swift, K.C., and Mr. A. Neilson appeared for the plaintiff; Mr. Clavell Salter, K.C., and Mr. R. A. Wright for the defendants.

The plaintiff, on December 5, 1913, entered into an agreement with the defendants for the medical treatment of insured persons under the Acts of 1911 and 1914, and he had been placed by the defendants on the panel of medical practitioners. By Clause 1 the Acts of 1911 to 1913 and the National Health Insurance (Medical Benefit) Regulations (England), 1913, or other regulations in force in the area of the committee were incorporated in the agreement. The plaintiff was to be paid in accordance with the provisions of Part IV. of the schedule to the regulations on the basis of the rate of 1s. 7½d. a quarter for persons included in his list at the beginning of the quarter entitled to medical benefit.

In March, 1914, a sub-committee, called the joint committee for the checking of prescriptions, was appointed, consisting of two members from the Insurance Committee, two members from the Panel Committee, who were representative of the medical profession, and two members of the Pharmaceutical

Committee, who were representative of the chemists. The plaintiff, on October 23, 1914, was asked to meet that prescription checking sub-committee of the Panel Committee to explain certain prescriptions which seemed excessive and extravagant. The plaintiff attended the meeting and was told that whereas the average cost per prescription for the whole county during the first quarter of 1914 was 9d., the average cost of his prescriptions was 3s. 4d. There was a deficiency in the drug fund of about £7,000 for the year.

After considering the matter the Panel Committee resolved to recommend that the plaintiff be surcharged the sum of £323 2s. 8½d. This report of the Panel Committee was considered by a sub-committee of the defendant committee, who resolved that the excessive demand on the drug fund had arisen because the orders given by the plaintiff had been extravagant, and that the sum of £323 be deducted from the amount payable to him by the committee, and that the amount so deducted be credited to the drug fund.

The defendant committee on March 1, 1915, passed a resolution to surcharge the plaintiff £323 2s. 8½d., and notice of that surcharge was sent to the plaintiff on March 8, 1915.

As the Insurance Commissioners had held in another case that a doctor had the right to be heard before the full Panel Committee, and as the plaintiff had only been heard before a sub-committee of the Panel Committee, the defendants on March 10 told the plaintiff that they had remitted the matter of his surcharge to the Panel Committee for further report.

On March 15, 1915, Dr. Brackenbury, the chairman of the Panel Committee, sent to the clerk of the defendant committee a draft model report prepared by the British Medical Association, and added:—

Of course, it will not be followed too closely in the present case, but I suppose it will give us the necessary outline and some suggestions. If you could get some such report drafted with as much detail included as is possible, and let us have it with such documents as are necessary for our inquiry (those we had on the last occasion, I suppose by Thursday week), I should be greatly obliged.

—meaning the inquiry by the Panel Committee into the plaintiff's case. On March 17 the secretary of the Panel Committee wrote to the plaintiff that his committee were advised that he (the plaintiff) should have an opportunity of appearing before the full Panel Committee with reference to the surcharge and fixing an appointment and setting out the main facts disclosed by an examination of his prescriptions, the first of which was that the average cost of each of his prescriptions was 2s. 4½d., the average for the whole county for the same period being about one-third of that amount.

The plaintiff's solicitors replied that the Insurance Committee were *functus officio* by reason of their previous decision, and that they had advised the plaintiff not to attend the meeting fixed.

The clerk of the defendant committee replied to Dr. Brackenbury on March 18 that he would let him have a report drafted on the lines suggested in time for the meeting.

The defendant committee on April 12 formally rescinded the resolution of March 1 and referred the report of the Panel Committee back to them for further consideration. The plaintiff was then invited to attend the meeting of the Panel Committee. This he did under protest that the regulations were illegal and *ultra vires*, and that any report or resolution of the committee could not be enforced against him, and he refused to answer any questions or to offer any explanation. The Panel Committee then made their report, which was considered by the General Purposes Sub-committee of

the defendants, and on May 3, 1915, the defendant committee resolved to surcharge the plaintiff £323 2s. 8½d.

Regulation 40 of the National Health Insurance (Medical Benefit) Regulations (England), 1913, provided:—

(1) Where it appears to the Panel Committee that by reason of the character or amount of the drugs or appliances ordered for insured persons or by any practitioner or practitioners on the panel the cost of the supply of those drugs and appliances is in excess of what may reasonably be necessary for the adequate treatment of those persons, the Panel Committee may and if any representations to that effect are made to them by the Pharmaceutical Committee, shall make an investigation into the circumstances of the case, whether in respect of the drugs and appliances ordered by an individual practitioner or generally as to the orders given for drugs and appliances by practitioners on the panel.

(2) The Panel Committee shall, after hearing the Pharmaceutical Committee and any practitioner concerned, make a report to the Committee, and if after considering the report the Committee are of opinion that an excessive demand upon the Drug Fund has arisen owing to orders given by a practitioner which are extravagant either in character or in quantity they may, if they think fit, make such deduction from the amount payable to that practitioner by the Committee as they think fit and shall pay the amount so deducted to the credit of the Drug Fund: provided that the practitioner shall be entitled to appeal to the Commissioners, whose decision shall be final.

JUDGMENT.

Mr. Justice Rowlatt, in giving judgment, said that he had no jurisdiction to decide whether the plaintiff had been extravagant or not; all that he had to decide was whether the defendants had the right to surcharge him, and, if they had that right, whether they had exceeded their powers. It was clear that persons who had to discharge judicial functions must discharge them in strict conformity with the terms of the instrument which conferred those powers. In the present case the power to surcharge was conferred by Regulation 40 of the National Health Insurance (Medical Benefit) Regulations, England, 1913. His Lordship read it, and continued: That regulation not only gave the Panel Committee judicial power, but also gave them the power to initiate an investigation, and if the Pharmaceutical Committee made representations to them that any medical practitioner had been extravagant, the Panel Committee was bound to make investigations. In his (his Lordship's) opinion, it was not necessary that every step of that investigation should be attended by the medical practitioner, but he had undoubtedly a right to be heard, and must be given an opportunity of looking into the matters which were being investigated, and of challenging any point which he disputed. In the present case the Panel Committee had their attention drawn to the matter by a sub-committee. They thereupon instructed an expert to look into all the prescriptions. This he did with great minuteness. The matter was then considered by a sub-committee in October, 1914, who heard Dr. O'Neill and reported to the Panel Committee. That sub-committee was the wrong body to hear him; their report, therefore, was not binding. It was said, therefore, that that was an end of the matter. In his Lordship's opinion that was not correct; the proceedings were a nullity and there was no decision, and there had to be a decision, unless the matter was to be allowed to drop.

The matter was then referred back to the Panel Committee, who held a second meeting on April 22, 1915, of which they gave the plaintiff notice. He attended, but refused to answer any questions or give any information. It was true that the com-

mittee had already gone fully into the questions, and had come to a conclusion that the case was rather black against the plaintiff; but that, in his Lordship's opinion, did not render the committee incapable of reopening the question. He could not hold that this second meeting was a pretence. As the plaintiff refused to speak it could not be said that he had not had a full and proper opportunity of being heard.

He then came to the more important point in the case, namely, whether Regulation 40 was *ultra vires*. That depended on the Act. Section 65 of the Act of 1911 gave the Commissioners power to make regulations (*inter alia*) "generally for carrying this part of this Act into effect." It was said on behalf of the plaintiff that this regulation was not within the scheme of the Act at all. Section 8 of the Act laid down the benefits to which insured persons were entitled, and section 15 (5) gave them the right to choose their doctor and provided for the supply of drugs and medicines. In his Lordship's opinion, it did not give the doctor an uncontrolled discretion in the matter. It was obvious that there must be a limit to the amount available, and apart from that it appeared to him that there was a duty imposed upon a doctor to prescribe reasonably. The Act did not, of course, contemplate that the patients were to be stinted, but the doctor was not to be extravagant or reckless in ordering medicines that were unnecessarily expensive. In order to carry out the Act it was necessary to provide some means of checking extravagance, and this rule was made for that purpose. It was consequently a rule which came within the powers conferred on the Commissioners for carrying the Act into effect. There would be judgment for the defendants with costs.

Solicitors.—Mrs. Hempsons for the plaintiff; Messrs. Charles Rogers, Sons, and Abbott for the defendants.

OBITUARY.

DR. EVAN LLOYD, M.B., C.M., J.P.,
TREGARON.

DR. EVAN LLOYD passed away on December 15th, at the age of 64 years. He was seized with an illness a few years ago, which never entirely left him, and although it was once thought his recovery was complete, the complaint periodically recurred. Born in 1851, the late Dr. Lloyd proceeded to Glasgow as medical student, and there, in 1876, he graduated M.B., B.S. Returning to his native county, he started in practice at Tregaron. He soon built up an extensive practice, and was appointed to the posts of Medical Officer to the Tregaron Workhouse and Medical Officer of Health to the Rural District Council. His annual report to the Council had of late years attracted considerable attention by his efforts to improve the sanitary condition of the district, and in that direction he did successful work. He was appointed a county magistrate in February 1899, and a member of the Cardiganshire County Council in March, 1901. Three years ago he was appointed to succeed the late Dr. Abel Evans as Coroner for Mid-Cardiganshire. He leaves a widow and family of eight.

DR. S. R. DUDLEY, L.M.S.S.A., ILFORD.

THE death of Dr. Samuel Robert Dudley took place at Ilford on December 21st, after a short illness. Educated at St. Bartholomew's Hospital, he qualified L.S.A. in 1901 and L.M.S.S.A. in 1907. The deceased, who was 54 years of age, leaves a widow, but no family.

DR. C. H. FOX, M.D., M.R.C.S., F.R.C.P.,
EDINBURGH.

THE death took place on Christmas Day, at 35 Heriot Row, Edinburgh, of Dr. Charles Henry Fox.

He was aged 78. The deceased gentleman took the degree of M.R.C.S.Eng. in 1850, his M.D. at St. Andrew's and F.R.C.P. Edin in 1900. He was educated at St. George's and Edinburgh. He was formerly Physician to and joint proprietor of the private lunatic asylum, Brislington House, Bristol.

DR. A. F. BLAGDON RICHARDS, M.A., M.D.,
M.R.C.S., L.R.C.P., SWANSEA.

THE death has taken place, at Swansea, of Dr. A. F. Blagdon Richards, who was connected with Swansea Hospital for some years as a throat and nose specialist. Dr. Richards was 51 years of age, belonged to an old Carmarthenshire family, and was educated at Cambridge, qualifying M.D. in 1896. He practised with great success for about 25 years in Swansea, but had a complete breakdown in health some time ago. He leaves a widow and one son.

REVIEWS OF BOOKS.

AIDS TO PHYSIOLOGY. (a)

AN important number in the Aids Series is that on Physiology, a new edition of which has recently made its appearance, the two previous editions coming from the pen of Prof. Peyton Beale. This new presentation of the essential facts of physiology has been edited and partly re-written by Dr. John Tait, Lecturer in Experimental Physiology in Edinburgh University, and by Dr. R. A. Krause, and we have read it with pleasure and profit. It is pleasantly written, up to date, and the author's views on matters of controversy are clearly stated. Conflicting opinions are excluded, but in every instance of this kind we are in agreement with the author. We heartily commend the book alike to the student and the practitioner who wishes a bird's-eye view of modern physiology. At the same time there are points which in our judgment call for criticism in view of future editions. Naturally, the most important failing in a work of such small size (250 pp.) is that certain sections are dealt with much too briefly—for instance, those on the pulse, and the spinal cord as a reflex centre. We venture to think that twenty valuable pages might have been saved by referring readers to "Aids to Histology" instead of giving them a mere *résumé* of histology in the present work, thus affording more space for the fuller development of points unnecessarily condensed. We must congratulate the author on a very careful revision of proof; we have not discovered a single misprint, although through some carelessness in revision we are told in one line that the pulse-rate in old age is 60 or less, and almost in the next that the heart's action in extreme old age is quickened. The word "sensory" is frequently used when "afferent" is intended. "Basophil" is spelt "basiphil" wherever it appears. This may be justified on etymological grounds, but is contrary to usage. These, however, are minor points which will doubtless be noted in the next edition.

ST. THOMAS'S HOSPITAL REPORTS. (b)

WE have nothing but praise for the form in which the staff of St. Thomas's Hospital publishes its Annual Report. First comes a statistical statement of the diseases and injuries treated in the medical, surgical, and gynaecological wards, giving particulars as to age and result. This is followed by a critical analysis of the various cases of each disease and the treatment adopted, together with brief notes on the more interesting cases. This part of the book is of the greatest value, and we are filled with admiration,

(a) "Aids to Physiology." New edition. By John Tait, M.D., D.Sc. Edin., and Robert A. Krause, M.D., D.Sc., D.P.H. Edin. and Glasg. Pp. 250, with 32 illustrations. London: Baillière, Tindall and Cox, 1915. Price 3s. 6d. net.

(b) "St. Thomas's Hospital Reports." New Series. Edited by Dr. J. J. Perkins and Mr. C. A. Ballance, F.R.C.S. Vol. XI. Pp. xii, and 217. Vol. XLII, pp. xii and 237. London: J. and A. Churchill.

not only for the enormous amount of careful work recorded, but for the industry and skill of the various registrars who have handled such a mass of material so capably. Many points of interest appear in these pages. We are surprised to note that in two cases of typhoid fever in one year the Widal test was negative, although in one of them the typhoid bacillus was recovered in pure culture from the blood. This must be a very unusual experience. We note with interest that a case of pulmonary abscess treated with an autogenous streptococcal serum recovered, whereas one treated surgically died. Ligation of the superior thyroid artery has been practised for Graves' disease, but the results do not appear encouraging. Out of 87 cases of salpingitis and 62 of pyosalpinx and tubo-ovarian abscess, tuberculosis is only noted as being present in two cases. The reports of other gynecological departments show tuberculosis to be the cause of between 30 and 40 per cent. of the cases of salpingitis and pyosalpinx that come to operation. An instance is mentioned of a six months' pregnancy in a uterus the subject of carcinoma of the cervix. The mortality in eclampsia was very high—six deaths among twelve cases. The information given as to the treatment of eclampsia is silent on the point of feeding. The maternal morbidity in the puerperium is very high—20 per cent. in 1911, and 24.2 per cent. in 1912. No information is given as to the treatment adopted for sepsis. We note that about one-fifth of the morbid cases is classed as "sapræmia," a term which should have disappeared by now from scientific nomenclature. Another one-fifth is classed as "reactionary"! The obstetric reports are the least satisfactory in the volume.

SURGERY. (a)

IN these days of competitive publication, when the market is flooded with so many hastily compiled and slovenly written text-books, it is with a sense of genuine pleasure that we turn to a new edition of "Thomson and Miles." These volumes represent the best teaching of the Edinburgh school; the style is fluent and easy, the text is enriched with numerous well-chosen photographs and radiograms, and there is a delightful absence of "padding."

In spite of the difficulty of compressing within the space of two small volumes a complete account of modern surgery, there is little of clinical importance omitted or passed over in these volumes. Descriptions of operative *technique* have been relegated to a third and independent volume; succinct outlines of pathological processes are given wherever necessary; and the authors are to be congratulated upon the successful production of a really good student's text-book of clinical surgery.

The individual sections are so arranged that there is little overlapping; points of differential diagnosis and indications for treatment are clearly summarised; preceding each section is an admirable *résumé* of the chief points of importance in the applied anatomy and physiology of the organs under consideration; and nearly all the sections have been brought up to date by ample reference to more recent work.

In dealing with the problem of surgical shock, the conflicting theories of Crile and of Henderson are both considered. In discussing treatment for the prevention of the condition, we were surprised at the absence of any reference to the intravenous injection of saline or Ringer solutions; nor is there any mention of the occasional good effects produced by the use of pituitrin. We warmly commend the authors' plea for a more extensive application of Bier's hyperæmic treatment in acute inflammations.

The chapter on syphilis is thorough and modern. In considering the treatment of tuberculous disease in bones and joints, the authors recommend a judicious adherence to conservative methods in young subjects, whilst direct operative interference is, in their

opinion, more suitably reserved for more adult patients. The authors' method of description of injuries of bones and joints is admirably arranged, each region being taken up in turn, and a clear, concise account rendered of the principal fractures and dislocations which may be met in individual areas; thus, fractures and dislocations in the neighbourhood of the shoulder joint are considered together, and so on. This method of grouping should greatly facilitate the study of these injuries for the student. Clear indications are laid down for operative intervention in fractures where older methods of treatment have failed to yield wholly satisfactory results.

The account of the surgery of the thyroid gland is disappointing. The brief ætiological summary is guiltless of any reference to iodine metabolism; the description of Graves' disease is scanty and hurried; and there is only the most cursory reference to the parathyroids. In the chapter on carcinoma of the breast, we think a more detailed account of Handley's work might have been included with advantage to the student.

Some 250 pages are devoted to abdominal surgery. The early operation for appendicitis is warmly advocated, and the "saccular theory" of hernia formation also obtains the authors' support. The relationship of chronic gastric ulcer to gastric carcinoma is emphasised. The account of intestinal obstruction is clear, and there is a concise description of recent clinical findings on the vexed question of intestinal stasis.

Throughout both volumes (save for the section on the thyroid gland) the authors have striven successfully to render this new edition thoroughly representative of the best modern opinion. Their teaching is in no wise too dogmatic in a field where a too emphatic dogmatism is always dangerous. We can recommend the student who is starting to walk his hospitals no more reliable text-book than this with which to complement his studies at the bedside and in the theatre.

THE YEAR-BOOK OF PHARMACY. (a)

FOR half a century the "Year-Book of Pharmacy" has been of great theoretical and practical value to pharmaceutical chemists, and it has become a valuable book of reference. During the fifty years of its publication, pharmacy has made immense strides forward, and the literature of pharmacy has correspondingly increased; this progress entailed much extra work on the editor of the annual. It is no light task to issue a readable and practically useful summary of the progress of pharmacy in the space at the editor's command. We refer to these things because we think that the annual must either be enlarged or some of its sections be deleted. The section Chemistry consists of condensed abstracts, well chosen and interesting, but too brief to be of practical value to the manufacturer, and too technical to be followed by the great majority of compounding pharmaceutical chemists; and medical practitioners cannot give time to the chemistry of the alkaloids or the study of open and closed chains and the influence of alkyl radical substitutions in modifying physiological action of a drug. "New Remedies and New Applications of Remedies" contains in a few pages a great deal of useful information, especially now, when German synthetic chemicals are unattainable. "Pharmacognocny" gives some interesting abstracts on belladonna, hyoscyamus, and other familiar herbs, which are suffering destructive attacks in the United States from the potato bug. Belladonna, foxglove, henbane, and stramonium grow to great perfection in Ireland, and some effort might be made so to cultivate them that we might be independent of imported supplies. Dispensing naturally occupies a large

(a) "Year-Book of Pharmacy, containing Abstracts of Papers relating to Pharmacy, Materia Medica, and Chemistry, contributed to British and Foreign Journals from July 1st, 1914, to June 30th, 1915, with the Transactions of the British Pharmaceutical Conference at the Fifty-Second Annual Meeting, held in London, July 14th, 1915." Editor of the Abstracts, J. O. Braithwaite. Compiler of the New Remedies Section, J. Stephenson, F.R.S.E. Editor of the Transactions, R. R. Bennett, B.Sc., F.I.C. London: J. and A. Churchill, 7, Great Marlborough Street. 1915.

(a) "Manual of Surgery." By Alexis Thomson, F.R.C.S.Ed., and Alex Miles, F.R.C.S.Ed. Vols. I. and II. Pp. 801 and 948. Fifth edition, revised and enlarged. London: Henry Frowde, Hodder and Stoughton. 1915.

amount of space, and the section well repays reading by those who desire to prescribe active drugs in a palatable form. Revision notes are a series of criticisms on the 1914 Pharmacopœia, some of which are severe and well deserved. "The Presidential Address" is an appeal to the members of the Society to organise a movement for the establishment of a Royal Army Pharmaceutical Corps to look after the pharmacy of the Army. Many excellent arguments are put forward in support of the scheme; but at present so many difficulties beset the Government that there is little prospect of the President's suggestion being carried out.

MEDICAL NEWS IN BRIEF.

Dr. Steevens' Hospital, Dublin—The Steel Memorial.

An interesting ceremony took place at Dr. Steevens' Hospital, Dublin, on St. Thomas' Day, December 21st, when his Grace the Lord Archbishop of Dublin, at a special evensong service, dedicated a lectern placed in the chapel of the hospital by the Governors and staff to the memory of Major Edwin Steel, R.A.M.C. When a student, Steel spent several years as a resident pupil in Steevens' Hospital, where the thoroughness of his work and the sterling qualities of his character made for him many warm friends. Steel graduated in Medicine in the University of Dublin in the summer of 1893, and in January, 1895, entered the Royal Army Medical Corps. In the nineteen years that he served in that corps he saw much service. He was for two periods in India, where he specially distinguished himself for his work in connection with the plague, and for which he was made an Associate of the Order of St. John of Jerusalem. He also held the South African war medal and the Durbar medal. When the present war broke out Steel was in command of the hospital at the Higher Barracks, Exeter. In August, 1914, he went to France in command of Field Ambulance No. 20, and for his work with it was mentioned in dispatches by Sir John French. In October, 1914, Steel was appointed Assistant Director of Medical Services with the first Cavalry Division. While on this duty he was, on November 23rd, wounded at La Clytte, by shell fire, and died the same day. The handsome brass lectern in the chapel of his old hospital will form a visible token of the honour in which the memory of Edwin Steel's short but full life is held by some of those who knew him well.

Allen and Hanburys Bi-Centenary.

At Liverpool Street Hotel, on December 18th last, the employees of Messrs. Allen and Hanburys, Ltd., at home and abroad, presented to the Vice-Chairman, Mr. Frederick Janson Hanbury, his portrait, painted by Mr. Percy Bigland, and a cabinet of silver to his co-director, Mr. W. Ralph Dodd, with illuminated addresses.

Mr. F. W. Gamble (Chairman), in making the presentations, referred to the completion of a period of 200 years since the establishment, in the City of London, of the firm. He stated that the formation of the Plough Court Pharmacy were laid by Silvanus Bevan. William Allen, F.R.S., was a man of the most strenuous activities and of European renown as a scientist and philanthropist. He became the first president of the Pharmaceutical Society on its foundation in 1841, and was one of those named in the Royal Charter of Incorporation granted in 1843. At this time the Plough Court Pharmacy produced another great man, Daniel Hanbury, F.R.S., whose name and work are commemorated by the Hanbury medal, awarded periodically to the most distinguished international worker in pharmacognosy, Daniel Hanbury's favourite subject. To-day the Chairman is Mr. Cornelius Hanbury, who attains next year to his golden jubilee as a partner in the firm.

Mr. Frederick J. Hanbury, in his reply, said that when he first entered the business, it was accom-

modated in the two old houses, built after the Great Fire of London in Old Plough Court. In the early part of last century most of the anti-slavery meetings were held at Plough Court, where Lord Brougham, Wilberforce, Clarkson and other pioneers of this grand work were constant visitors.

Mr. Dodd said he had never known a time in all his business career when it was so very difficult to carry on the business. He claimed that Allen and Hanburys may take the credit, in no small degree, for the striking improvement in recent years in the statistics of infant mortality, pointing out that the "Allenburys" system of infant feeding is now well established and recognised by the medical profession. It is very widely used, and has been the means of saving many thousands of lives.

The Royal Society of Medicine.

At the meeting of the Electro-therapeutical Section on January 21st, at 8.30 p.m., a paper will be read by Dr. E. P. Cumberbatch on "The Simpson Light," and he will also give a demonstration of the apparatus.

At the next meeting of the Surgical Section, on Wednesday, February 2nd, 1916, at 5.30 p.m., Dr. Hernaman-Johnson will give a demonstration of the use of condensers in the treatment of nerve lesions, and will read a paper on "The Use of Condensers; and the Diagnosis, Prognosis and Treatment of Nerve Lesions." The demonstration will be of particular interest to neurologists and those practising electro-therapy.

Medical Society of London.

THE next meeting of the Society will be held on Monday, January 17th, when a discussion on "Gun-shot Wounds of the Chest" will be introduced by Col. Sir John Rose Bradford, F.R.S., R.A.M.C., and Capt. H. Morrington Davies, R.A.M.C., F.R.C.S., Lieut.-Col. Hale White, M.D., R.A.M.C., and others will take part in the discussion. Fellows and others desirous of taking part in the discussion are requested to communicate with the Hon. Secretaries or the Registrar.

Ninety-Seven Degrees of Frost.

INTENSE cold has prevailed for some weeks over the whole of Scandinavia, resulting in temperatures lower than have ever been registered at this time of year. The degrees of frost Fahrenheit were:—Stockholm, 40; Christiania, 43; Vardö (in Finmark), 72; Jemtland (Swedish Province), 97. The last temperature is the lowest ever observed at any place in Scandinavia.

The King's Inspection of Ambulances — Northern Miners' Gift.

THE KING recently inspected in the grounds of Buckingham Palace 25 fully equipped motor ambulances provided for foreign service by the miners of Lancashire and Cheshire and presented by them to the British Red Cross Society.

The cars form half of a convoy of 50, the other half of which will be presented by the coalowners in the two counties. Those inspected by the King cost about £18,000. The ambulances are specially adapted for hill climbing and the rough work of a campaign. Lord Derby, who recently inspected them, was so much pleased with the convoy that his brother, the Hon. Arthur Stanley, Chairman of the British Red Cross Society, requested the King to inspect the cars before they were sent away.

The ambulances were drawn up in the Mall and driven to the Palace grounds, where His Majesty inspected them, one car being examined in detail. The King expressed his approval of the completeness of the equipment, and also his keen appreciation of the generosity of the miners.

Sir Ernest Cassel's Gift.

SIR ERNEST CASSEL has given £25,000 in War Loan stock to the Joint Committee of the British Red Cross Society and the Order of St. John.

A week ago it was announced that Sir Ernest

Cassel had given £50,000 4½ per cent. War Loan stock to hospitals and kindred charities to be distributed on the same lines as his previous donation of £50,000 in 1911—that is, partly in direct gifts and partly through King Edward's Hospital Fund.

British Hospital Staff as Prisoners.

THE number of members of the British hospital units who have returned from Serbia to London is about 90. They speak of the terrible sufferings of the unhappy Serbians, many of whom, both men and women, lay dead along the sides of the roads followed in the retreat. The British Farmers' unit are, the returned doctors and nurses say, prisoners in the hands of the Austrians, and a similar fate has befallen many members of the staff of the Scottish Women's Hospital. The latter were at Krujevatz when last heard of. The British Red Cross Society announce that all their Montenegrin units under Dr. Clemow have arrived safely in England.

Nose Drill.

IN the *New York Medical Record*, Dr. E. Harrison Griffin asserts that more than 75 per cent. of catarhal cases that come to the attention of physicians are due to the improper use of the handkerchief, and recommends that children in public schools should be instructed in nose drill. Dr. Griffin thus describes the correct method of nose-blowing:—"It is best to take a deep inspiration to fill the chest with air, after a finger is placed upon the side of one nostril to obstruct the passage. With one violent expiration the air from the chest is forced through the open chamber of the nose. This is repeated on the other side of the nose."

Death for Malingering.

A MESSAGE from Paris states that a court-martial sitting at Clermont Ferrand has condemned to death two French soldiers who, on the eve of the battle of Champagne, deceived the doctors into believing they were suffering from abscesses, with the result that they were removed to hospital. It was afterwards discovered that the "abscesses" were artificially produced.

Red Cross Donations.

RESPONDING to an appeal by the Lord Mayor, the Mercers' Company, in addition to previous contributions, have given £500, the Clothworkers' Company £500, the Skinners' Company £105, and the Cutlers' Company £100 to the funds of the British Red Cross Society and the Order of St. John of Jerusalem (Joint War Committee).

Red Cross Work at Malta.

THE British Red Cross Society has received the following telegram from Lord Methuen, under date, December 27th:—"His Excellency the Governor of Malta wishes to express his hearty thanks to the committee and staff of the British Red Cross and Order of St. John for their admirable organisation for the comfort of the men at Christmas. His Excellency witnessed for himself the happiness of the patients in every hospital on Christmas Day from the successful efforts of the committee and those ladies helping under their guidance."

Medical Sickness and Accident Society.

AT the usual meeting of the Committee held last month, Dr. F. J. Alden in the chair, the reports submitted showed that during the month of November the claims for sickness had risen slightly above expectation, but that for the whole year, so far, the total experience is below the total expectation. In spite of the congestion of business generally, owing to the war, it was reported that new proposals received were greater in number than those for the same period in the preceding year. The number of additional proposals received has been fairly well maintained. One satisfactory feature noted was the

increase in the combined Sickness and Accident and Life Assurance contracts issued, and the tendency among existing members to avail themselves of the opportunity of increasing their insurances in the Society by the addition of Endowment Life Assurances, payable at the age of 65, or previous death.

The number of claims from members on active service have, fortunately, been few, in comparison with the total number who are serving in the Royal Army Medical Corps and similar forces. The complete figures of this item will probably be included in the Chairman's speech at the next annual general meeting.

University of London—The Reitlinger Prize.

THE Paul Philip Reitlinger Prize, offered in 1915 for the best essay on "The Economic Condition of the People of England in 1815 in Comparison with the Present Day" has been awarded to Herbert Roland Hodges, of the London School of Economics. The prize, this year of the value of £40, was founded with funds given to the University by Mr. Albert Reitlinger in memory of his son, a student of St. George's Hospital Medical School, who died on December 3rd, 1911. Next year the prize will be awarded for the best essay embodying the result of some research work on a medical subject carried out by the candidate.

Federated Malay States Hospital.

A HOSPITAL for soldiers has been established at Blackmore End, Kimpton, Herts, generously lent for the purpose by Mrs. Vincent, of Blackmore End and 35 Portman Square. The funds have been provided by the public of the Federated Malay States, all classes of the community, Malay, Chinese and Indian, as well as European, having contributed liberally. The hospital is under the charge of Captain G. D. Freer, R.A.M.C. (T.), formerly Senior Medical Officer, Selangor, F.M.S.

Typhus among British Prisoners.

MEN from the camp at Wittenberg give a dreadful account of the lack of medical care there, which, they declare, is causing hundreds of deaths from typhus. Nearly a hundred British have died in this way.

Queen's Nurses and War Work.

AT a meeting of the Council of the Queen Victoria's Jubilee Institute for Nurses it was reported that 557 Queen's nurses were away from their districts, as they were undertaking duty in connection with the war; in some instances the associations were working with a smaller staff, and in many cases non-Queen nurses were being employed temporarily.

Oxford University.

THE following candidates have satisfied the examiners for the Diploma in Public Health:

Part I.—Elizabeth F. Butler, James T. MacManus, and Richard H. Vercoe.

Part II.—Edgar B. Argles, Thomas R. Bowen, and Effie G. Brander.

University of London.

THE following candidates have passed the M.D. examination:—Branch I. (Medicine): Abraham S. Erulkar, B.S. Both in Branch IV. (Midwifery and Diseases of Women): Lilius M. Blackett, B.S. (University Medal), Dorothy C. Logan, B.S.

The following have passed the second examination for medical degrees, Part II.:—Oliver St. Leger Champion, George Day, William Eidinow, Walter A. Flynn, Walter H. Grace, Algernon S. Green, Alice M. Griffiths, Blanch A. M. Henderson, Jerusha J. Jhirad, Constance A. Jones, B.Sc., David M. Jones, Daulat M. Lala, Robert L. Portway, Reginald H. Sunderland, Charles H. Warner, B.Sc.

London School of Tropical Medicine.

THE following is a list of candidates who have passed the examination—October to December 1915:—V. A. Goonetilleke (Ceylon Medical Service,

L.R.C.P., L.R.C.S.Edin., L.M.S.Ceylon, M. de Costa, M.R.C.S., L.R.C.P., D.P.H., T. Ryan (West African Medical Service), M.B., B.Ch., B.A.O., E. J. Rowbotham, M.R.C.S., L.R.C.P.Lond., R. J. Tata, L.M. and S.Bombay.

Dublin University.

The following candidates have passed the Trinity College School of Physic Michaelmas Examinations:—

Preliminary Scientific.—Chemistry: Derrick H. G. Fishbourne, Henry A. Lavelle, John C. J. Callanan, William J. Hogan, Eric W. Harris, George R. L. Jordan, John G. Holmes, Mayo F. Meade, Edward H. Montgomery, Jacobus F. Van Staden, Samuel J. Laverty.

Physics.—Charles W. Parr, Thomas F. L. Cary, George R. L. Jordan.

Botany and Zoology.—John F. Sheppard, Victor G. Walker, Richard D. Murphy, John G. Holmes, Derrick H. G. Fishbourne, Eileen H. Dowse, Patrick J. Healy, Albert V. Foster, Harry C. Dundon, Edward H. Montgomery, Patrick J. Duggan.

Intermediate Medical.—Part I.—Anatomy and Physiology.—Eric J. Lyndon, William F. McConnell, John B. McGranahan, Cecil Keller, William L. Young, Percival A. Dormer, Kenneth Greer, James M. Hill, Thomas Tabuteau, Joseph Posner, Daniel McElwee, Frederick J. Dymoke, Frederick W. Godbey, James A. W. Cullen, Jason G. Bird.

Intermediate Medical.—Part II.—Applied Anatomy and Applied Physiology.—Charles G. Ambrose, Percy C. Parr, Margaret Wolfe, Patrick Casey, William J. Hamilton, John E. Hill, Meta G. Jackson, Frederick J. Dymoke.

Final Medical.—Part I.—Medical Jurisprudence and Hygiene, *Materia Medica* and Therapeutics and Pathology.—Andrew H. Davidson, William F. Wicht, Philip A. Hall, William Garde-Browne, Joseph G. Bird, Robert W. Prichard, John P. Macnamara, James B. Taylor, Hastings H. Molloy (Pathology, Medical Jurisprudence and Hygiene), Millicent Hamilton-Johnstone (Pathology), Michael C. Dippenaar (*Materia Medica*, Medical Jurisprudence and Hygiene).

Special Final, Part II.—B.Ch. (Surgery).—Geraldine Murphy, Herbert Mitchell, Cecil McL. West, William F. Wilson, Cecil G. Sherowitz, William B. Walker, Godfrey Bateman, Thomas W. Sweetman, Robert L. Vance, Roland H. Graham, Joseph H. C. Walker, David H. Hall, Grosvenor L. Murphy, William Hunt, Arthur G. Fisher.

Special Final, Part II.—M.B. (Medicine).—Thomas W. Sweetman, Herbert Mitchell, Clara B. M. Adderley, Cecil G. Sherowitz, Edward Mannin, Thomas E. Beatty, Roland H. Graham, William Hunt, Arthur G. Fisher, Maurice B. King.

Special Final, Part II.—B.A.O. (Midwifery and Gynaecology).—John A. C. Kidd, John M. Ryan, Marie A. Hadden, Alan F. Grimbley, Luis Blumberg, Eileen G. Gwynne, Thomas G. Roche, Edwin Boyers, William Hunt.

Final, Part II.—B.Ch. (Surgery).—Thomas W. G. Johnson, George W. Doran, Thomas E. Beatty, Francis W. O'Connor.

Final, Part II.—M.B. (Medicine).—Alan F. Grimbley, Edward Lipman, Frederick J. Murphy, Robert L. Vance, Esther V. Adderley, Marie A. Hadden, David H. Hall, Violet M. Deale, Grosvenor L. Murphy, Francis W. O'Connor.

Final Medical Examination, Part II.—B.A.O. (Midwifery and Gynaecology).—Joseph W. Bigger, Thos. P. Chapman, Robert C. B. Ramsay, Clotilda B. Bevis, Rupert M. B. Gordon, Francis W. O'Connor, William Garde-Browne, Philip A. Hall, Charles L. McDonogh, William L. Bates.

M.D.—Brian D. Crichton, Rev. Ernest E. Lavy.
M.Ch.—Arthur Chance (high marks).
Preliminary Scientific Dental Examination.—Chemistry and Physics.—Irene O. Dorman.

Dental Anatomy.—Francis S. Judd.
Diploma in Public Health, Part I.—Ratan Edulji Dastur.

Diploma in Public Health, Part II.—Ratan Edulji Dastur.

Edinburgh University Graduation.

At the graduation ceremonial last week Principal Sir William Turner presided, and there was a large attendance. The following degrees were conferred:—

Degree of M.D.—Edwin C. Girling (lieutenant, R.A.M.C.), M.B., Ch.B. (in absentia), George D. Logan, M.B., C.M., Stewart M'Naughton, M.B., Ch.B., Adelaide A. Renshaw (née Dreaper), M.B., Ch.B., William Russell (lieutenant, R.A.M.C.), M.B., Ch.B. (in absentia), Charles P. Stewart (B.Sc.), M.B., C.M., Vattaparampil Sankara, Vallathan, M.B., Ch.B. (in absentia), Griffith J. Williams, M.B., C.M.

Degrees of M.B., Ch.B.—William Brownlee (M.A., B.Sc., New Zealand), Thomas F. Corkill (lieutenant, R.A.M.C.) (S.R.), Henry F. Ferguson, George W. M. Findlay (Surg. Prob., R.N.V.R.), Pratul Kumar Ghosh, Robert L. Impey (lieutenant, R.A.M.C.) (S.R.), Henry B. Kirk, Andrew J. M'IVor, Premrai Trambakrai Majmundar, Kumud Sankar Ray (M.A., B.Sc.), Arthur J. D. Rowan, Clement I. Stockley, Guy M. Torrance, Reginald A. Warters (B.A.Cantab), James A. Williams, Wyndham Williams (lieutenant, R.A.M.C.) (S.R.), Tin Po Woo (Ng), Margaret K. J. Wright, Peter H. Young.

Degree of D.Sc.—William F. P. M'Lintock, B.Sc.
Degree of M.A.—Pottipati Hanimireddigari Rama Reddi, B.Sc.

Degree of B.Sc. in the Department of Public Health.—James A. Henderson, M.B., Ch.B. (captain, R.A.M.C.) (T.).

Royal College of Surgeons of Edinburgh—The Fellowship.

At a meeting of the College held on the 15th ult., the following gentlemen, having passed the requisite examinations between 4th and 6th October, 1915, were admitted Fellows:—James Buchanan, M.B., Ch.B.Glasg., —Ruchazio, Shyama P. Chattopadhyaya, L.R.C.S.E., etc., —Halisahar, P.O.Bengal, Jacobus S. du Toit, M.D.Edin., Arthur O. Evans, M.B., Ch.B.New Zeal., James N. J. Hartley, M.B., Ch.B., Edin., Alfred W. Macbeth, M.D. C.M., Queen's University, Kingston, Ont., Canada, L.R.C.P. and S.

MEDICAL WAR ITEMS.

HIS MAJESTY THE KING has been graciously pleased to confer the Military Cross on the undermentioned officers in recognition of their gallantry and devotion to duty in the field:—

Temporary Captain Henry James Burke, Royal Army Medical Corps (attached 1st/8th Battalion West Yorkshire Regiment, Territorial Force). For conspicuous gallantry on 8th November, 1915, near Turco Farm. A sergeant in the front line had his leg crushed by the blowing in of a dug-out, and Captain Burke found immediate amputation necessary. In order to save time he crawled across the open to get his instruments, while the enemy turned a machine gun on him. In spite of their fire he returned the same way, and coolly performed the operation in the trench while the enemy were shelling it heavily.

Temporary Captain Bartholomew James Hackett, M.B., Royal Army Medical Corps (attached 7th Battalion Suffolk Regiment). For conspicuous gallantry and devotion to duty at Loos on 2nd October, 1915. When the battalion to which he was attached had suffered very heavy casualties and had run out of dressings, Captain Hackett brought up a fresh supply from the dressing station, crossing about 1,000 yards in the open. He has frequently attended the wounded under fire, and has shown great bravery.

Captain John EarnscloUGH Brydon, M.B., R.A.M.C., who has been wounded in France while attached to the Royal Field Artillery, Northumberland Division Ammunition Column (T.F.), was House Surgeon at the Darlington Hospital before the war, and previously held a similar post at the Bristol Children's Hospital. He took his M.B. degree at Edinburgh in 1908.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

CASPIAN (Applchy).—The news of the offer was received too late for notice in this issue.

J. N. (York).—You will see he has been mentioned in Sir John French's dispatch. He is with a field ambulance.

COLLOID (London).—Others have commented in the same strain.

THE GENERAL'S LOST TEETH.

In the retreat from Mons a distinguished general now commanding an army in France thought to snatch a few hours in bed in a peasant's cottage. He left his artificial teeth on the washstand. At night he was aroused with the news that the enemy was near, and hurriedly left, forgetting his teeth. After subsisting on light foods for a fortnight, the battle of the Marne brought the general back to the village. Although only the four walls of the cottage were left, one of the general's A.D.C.'s and three soldiers explored the wreckage. Under a lot of chicken bones and champagne bottles they found the teeth intact. The general then had a square meal.—*British Dental Journal*.

JAMAICA (Eastbourne).—Yes, Dr. Scott was the medical attendant at that time.

LARYNX (London, W.).—Reference is made to the matter in our editorial columns this week.

ACEYL (Bradford).—We understand that the whole question of the manufacture of Aspirin and other German products is to be brought to the notice of the House of Commons.

Vacancies.

- Bury Infirmary.—Senior House Surgeon. Salary £250 per annum, with board, residence, and washing. Applications to the Honorary Secretary, Infirmary, Bury, Lancs.
- Bury Infirmary.—Junior House Surgeon. Salary £150 per annum with board, residence, and washing. Applications to the Honorary Secretary, Infirmary, Bury, Lancs.
- Birkenhead Borough Hospital.—Junior House Surgeon. Salary £180 per annum, with board and laundry. Applications to the Secretary.
- Southwark Royal Eye Hospital.—House Surgeon. Salary £150 per annum. Applications to the Senior Surgeon.
- Burton-upon-Trent County Borough.—Assistant Medical Officer. Salary £300 per annum. Applications to John B. Chapman, Town Clerk, Town Hall, Burton-upon-Trent.
- Oxford Eye Hospital.—House Surgeon. Salary £100, with board and laundry. Applications to the Secretary.
- Bolingbroke Hospital (Incorporated), Wandsworth Common, S.W.—House Surgeon. Salary £200 per annum, with board-residence. Applications to the Secretary, Bolingbroke Hospital, Wandsworth Common, S.W.
- Worcester County and City Asylum, Powick.—Junior Assistant Medical Officer. Salary £250 per annum. Applications to the Medical Superintendent.
- Hereford County and City Asylum.—Assistant Medical Officer. Salary £250 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, County and City Asylum, near Hereford.
- South Devon and East Cornwall Hospital, Plymouth.—House Physician. Salary £240 per annum, with board, residence, and washing. Applications to P. J. Langdon, Secretary.

Appointments.

FRASER, D. H. M.A., M.D., B.C.Camb., Medical Officer of the St. Marylebone Parish Workhouse.

HULEY, J. M., M.B., Ch.B.Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Millom District of the county of Cumberland.

MACKEITH, JOHN, M.B.Glasg., Medical Officer to the Tuberculosis Department at the Central London Throat, Nose, and Ear Hospital.

Births.

GRAY.—On December 26th, at Alma House, Exmouth, the wife of Lieut. Robin Gray, R.A.M.C., of Stone House, Chipping Sodbury, of a daughter.

GUNN.—On December 28, at Melrose House, Perth, the wife of J. T. Gunn, F.R.C.S.Ed., Lieutenant, R.A.M.C., attached 18th Brigade, R.F.A., B.E.F.—a son.

LESLIE.—On December 26th, at Elm Lodge, Streatley, Berks, the wife of Leonard Leslie, M.D., of a daughter.

LONGRIDGE.—On December 27th, at 7 Oxford Parade, Cheltenham, the wife of C. Nepean Longridge, M.D.—a son.

MACRAE.—On December 24th, at St. Peter's Vicarage, Devizes, the wife of Major MacRae, R.A.M.C., of a son.

MORLEY.—On December 24th, at Somersby House, Barton-on-Humber, the wife of E. B. Morley, M.B., B.S.Lond., M.R.C.S., L.R.C.P., of a daughter.

OLLERENSHAW.—On December 22nd, at Palatine Road, Manchester, the wife (née Florence E. Watson) of Robert Ollerenshaw, F.R.C.S., Capt., R.A.M.C.T., of a son.

PRICE WATTS.—On December 28th, at Trelyon, High Road, Ilford, the wife of Dr. E. Price Watts, of a daughter.

THWAITES.—On December 30th, at 20 St. John's Park, Blackheath, the wife of Captain H. Thwaites, R.A.M.C., British Expeditionary Force, of a son.

TYLOR.—On New Year's Eve, at Mounpensey House, Wisbech, to Dr. and Mrs. Max Tylor—a daughter.

Marriages.

BOURKE—O'CONNOR.—On December 30th, at St. Dominic's Church, Haverstock Hill, N.W., Lieut. Ulick J. Bourke, R.A.M.C., elder son of Lt.-Colonel and Mrs. Ulick J. Bourke, R.A.M.C., The Firs, Hamilton, N.B., to Agnes Mary O'Connor, daughter of the late J. J. O'Connor and Mrs. O'Connor, India, and niece of Mr. and Mrs. Charles T. Strangways, Gilling Lodge, Hampstead.

MASON—EASTMAN.—On January 1st, Arthur F. Mason, R.A.M.C., 26th Field Ambulance, son of Mr. and Mrs. Mason, Steyne, Worthing, to Elsie Marion, eldest daughter of Henry Eastman, Fernlea, Southampton.

POWELL—COLE.—On December 29th, at Glencraig Church, Craigavad, Irvan Herbert Powell, B.A., M.B., B.Ch. T.C.D., second son of Lieut.-Col. C. K. Powell, M.D., R.A.M.C. (retired), 15 Cowper Road, Rathmines, Dublin, to Kathleen Harrietta Jacquetta, elder daughter of Lieut. T. Willoughby Cole, R.A.M.C.T., of Woodview, Innishannon, co. Cork, and Manor House, Dimington, Yorkshire.

PRESTON—BIGGS.—On December 27th, 1915, at St. Thomas's Cathedral, Bombay, Captain Arthur B. Preston, R.A.M.C., youngest son of the late A. Eley Preston, C.E., and Mrs. Preston, St. Maws, Cornwall, to Doris Winifred, youngest daughter of John Maudway Biggs and Mrs. Biggs, of Bratton Fleming, North Devon.

Deaths.

BTSBRY.—On New Year's Day, 1916, at Leamington Spa, Thomas Bushby, M.B., M.R.C.P., of Liverpool, aged 58 years.

DEBUS.—On December 9th, passed away at his residence, Cassel, Hesse, Germany, Prof. H. Debus, F.R.S., &c., late Lecturer on Chemistry, Guy's Hospital, Royal Naval College, Greenwich, &c., in his 92nd year.

DREW.—On December 27th, at Montrose, Battledown, Cheltenham. Joseph Drew, M.B., M.R.C.S., aged 89.

DUNLOP.—On December 30th, 1915, at Belgrave House, St. Helier, Jersey, Andrew Dunlop, Esq., M.D., D.P.H., F.G.S., aged 73 years.

JOHNSON.—On November 29th, killed in action at Anzac, Major Frederick Miller Johnson, A.M.C., late of Melbourne, Australia, M.D. Edinburgh, C.M. Lond., grand-nephew of the late Sir William Gull, Bart.

MILLER.—Killed in action in France, on December 29th, Albert Guy Miller, Captain, R.A.M.C., attached to the 12th Middlesex, Regt., husband of Marjorie Miller, of Weybridge, and fourth son of the late Albert Miller, Whernside, Toorak, Melbourne, aged 31 years.

OLIVER.—On December 27th, after a short illness, George Oliver, M.D., of Riversleigh, Farnham, Surrey (late of Harrogate), aged 74.

TANDY.—On December 30th, at the Red Cross Hospital, Finsbury Square, while acting as Resident Medical Officer, Barre Latter Tandy, L.R.C.S.I., L.R.C.P.Ed., aged 70.

THOMPSON.—Killed in action, on December 25th, Captain Arnold Bosanquet Thompson, M.B.Oxon., R.A.M.C. 1-3 East Lancashire Regiment Field Ambulance, fourth son of Arthur Thompson, of Garthlands, Reigate Heath, and 35 Mincing Lane, aged 29.

THOMPSON.—On January 1st, in France, Lieutenant W. Frank Thompson, R.A.M.C., of The Leys School, Cambridge, and St. Bartholomew's Hospital, dearly-loved elder son of Mr. and Mrs. W. W. Thompson, of 3 The Avenue, Brondesbury, aged 28 years.

WESTLAND.—On December 31st, at 22 Albyn Place, Aberdeen, Albert Westland, M.D., aged 62 years.

THE MEDICAL PRESS AND CIRCULAR

AT THE PERIPHERY.

"*Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer.*"—BEAUMARCHAIS.

Titles.

It is not as generally known as it ought to be that among the importunate seekers after titular distinction, medical men are, as a rule, conspicuous by their absence. Ministers, especially Prime Ministers, are constantly being bombarded by people desirous of rank, and the memoirs of several statesmen reveal the insatiable thirst for a handle to his name which seems to consume the ordinary man. Sir Robert Peel and Lord Beaconsfield both expressed themselves in terms of characteristic contempt of these rank hunters. The former, writing to a friend, said: "The distinction of being without an honour is becoming a rare and valuable one; it should not be allowed to become extinct." Dizzy, on being asked to give the Thistle to a Scottish peer whom he hated, said "Certainly not; if I gave it to him he would eat it." Fees in respect to honours used to be very heavy. The direct fees were nearly all abolished by King Edward in 1902, but, as it was shown in a discussion in the Commons not long before the war, the indirect fees are sometimes enormous.

Doctors and Titles.

MEDICAL men are fortunately altogether free from the suspicion of having bought their titles, a reproach which attaches to a not inconsiderable number of people thus distinguished. We are certainly sometimes surprised, not to say startled, when some of our number blossom forth into titles, as for example, when a general practitioner of Mayfair emerged from obscurity as Sir George Hastings. To explain his elevation the lay Press could find nothing more outstanding to record than the fact that he was Consulting Physician to the Gas Light and Coke Company. Such cases are, however, rare; and no one has ever been heard to suggest anything venal or mercenary in connection with them. It is far more often that we have to deplore want of recognition—at any rate of adequate recognition—for really good service of incalculable monetary value to the community.

Sir David Bruce.

OF this there is no better instance than the case of Sir David Bruce, the distinguished Surgeon-General to whom humanity owes the extinction of Malta Fever, and who has con-

tributed enormously to our knowledge of sleeping-sickness and other tropical diseases. He gained great military distinction in South Africa. Especially valuable were his services during the siege of Ladysmith. He has been in the forefront of scientific medico-military matters for many years, and enjoys the distinction, very unusual in military men, of being an F.R.S. The official recognition of his brilliant services to his country, to science and to humanity has taken the form of giving him the same rank as Sir Thomas Crosby and sundry provincial mayors. If there were any sense of proportion in the distribution of public rewards Sir David Bruce would have been given a Viscounty and a large sum of money. As things are, he is without any pecuniary reward and is on the same level of precedence with the consulting physician to the Gas Light and Coke Company.

Baronets.

THE only instance, so far as I am aware, of a medical man, *quâ* medical man, being raised to the peerage was the late Lord Lister, but there have been a great many medical baronets. The presidency of either of the Royal Colleges is now considered to carry a baronetcy with it. In the case of the Royal College of Physicians (of London) the first baronet was Sir Hans Sloane, who was president in 1719. Then came Sir George Baker in 1785. Since Sir Thomas Watson, in 1862, all the presidents have been baronets with two exceptions, Sir James Alderson, 1867, and Sir James Risdon Bennett, 1876, both of whom were Knights. There are now twenty medical men who have attained to this dignity; one of them, Sir Leander Starr Jameson, was thus rewarded for services other than medical. There are, I believe, but two medical men who have inherited baronetcies, Sir Hugh Beevor, who is the 5th Baronet, and Sir John Broadbent, who succeeded his distinguished father as 2nd Baronet in 1907.

Sir Ronald Ross.

SIR RONALD ROSS and Sir Henry Morris have both contributed to the discussion which has been taking place in the *Times* on the subject of whistling for taxis. Sir Ronald Ross, who, like Sir David Bruce, and perhaps to an even greater degree, has placed science and

humanity under a debt of profoundest gratitude, was, like the latter, originally in the Indian Medical Service. He was awarded the Nobel Prize in 1902, is an F.R.S., and carries after his name a long list of honorary degrees and fellowships. Official recognition in his case has taken the form of a K.C.B., which, though a degree or two higher than the Knight-bachelorhood conferred on Sir David Bruce, is still ridiculously inadequate to the value of his great, abiding and epoch-making contributions to science and the prevention of disease. Sir Ronald Ross has made the total extinction of malaria and allied diseases not only a possibility, but a probability, and has thus rendered the Tropics habitable by the white man. Sir Ronald is a poet of no mean order. Like Sir Victor Horsley, he is a convinced suffragist.

Whistling and Hooting. SIR HENRY MORRIS, who is a baronet in virtue of his former tenure of the Presidency of the Royal College of Surgeons, has more than once addressed the Editor of the *Times* on the subject of noisy taxis, and wrote last week a letter in reply to an anonymous "F.R.S." who had made the following three statements: (a) After midnight there is now no whistling nor motor-horn blowing. (b) The abolition of the motor horn would gravely increase the mortality among pedestrians. (c) Telephoning for cabs is useless. After pulverising (a) and (b) in his most vigorous manner, Sir Henry deals with (c) as follows: "The occasional failure of telephoning is more than paralleled by the frequent failure of the whistle. Enforced confinement to the house for some days has afforded me the opportunity of seeing that much of the whistling for cabs is as foolish as it is futile. Men and ladies with nothing to carry but an umbrella, a stick, or a muff will come to their street doors in fine weather, preceded by a servant who forthwith begins to whistle, and unavailingly continues doing so for double or treble the length of time required to walk to and pick up a cab in Regent Street or Oxford Street." Sir Henry concludes his letter on rather a pessimistic note: "But we are kicking against the pricks! It is not likely that either the State authorities or private individuals will take any steps during these troublous and perilous times of warfare, political unrest, and difficult economic problems to remove the scourge of noises, seeing that they would not raise a finger for our relief during the indifference, indulgence, and apathy of peace time."

I SINCERELY hope that this is not his last word on the subject. Some of us remember with gratitude that it was in war time that the London County Council bestirred itself to the point of putting a stop to the outrage of news-vendors bellowing their wares in alarmist tones through the residential quarters of the Metropolis, and if those who, like Sir Henry, are eminently qualified to speak on the present question, will keep on speaking in definite tones about the cruelty inflicted by whistles and horns upon the sick and suffering, there is every reason to hope that some good will come of it. To the abolition of hooting

there may be some reasonable objections, but to the abolition of that diabolical invention called the Klaxon there can be no objection whatever. Nor is there any defence for whistling after 11 p.m.

At the end of last month, at the Manchester Munitions Court, in reference to an application by an apprentice for discharge on account of gastric catarrh, in support of which a medical certificate was produced, the managing director of a munitions factory is reported to have delivered himself as follows:—"Without disparaging the doctors at all, I think I can say that we all know what family doctors are. You can get almost any kind of certificate from them." Dr. R. G. MacGowan, who is a well-known Manchester physician and a prominent member of the Manchester Insurance Committee, on having his attention called to the matter by a representative of the *Manchester Courier*, said: "A more unfounded charge it would be hard to imagine. I think it disgraceful that such a statement should be made. The charge, I notice, is worded in such a way that no individual is named, and therefore no legal action can be taken. It is very easy to bring such charges against a body of men, but it is not easy to prove them—in fact, in this instance it is impossible, because the statement made by the gentleman in the Munitions Court is simply not true."

Bounders and Greengrocers. I AM glad to see that Dr. MacGowan has expressed himself in this forcible manner. The members of the profession, as a rule, are far too docile in the presence of these preposterous attacks. To treat these semi-patronising vulgarities with contempt is, in a sense, a dignified attitude to adopt, but it is one which, if too long maintained, may easily give encouragement to the bounders and greengrocers who perpetrate them. The ordinary person can appreciate in others only such qualities as he himself in some degree possesses. Bounders and greengrocers are not necessarily imbued with a sense of the importance of their signatures at the foot of a document, unless the document happens to be a cheque, in which case the law impresses the importance upon them in a manner which may be disagreeable. They do not realise that a man's conscience can supply a more powerful deterrent than the fear of the law. But such is the case, and it is very much the case with members of the medical profession.

The "Star" Readers. I SEE that the *Star* is continuing its campaign in favour of Mr. Barker, the bone-setter. The War Office having had the audacity to refuse to allow this gentleman to treat recruits gratuitously, there is a tide of indignant correspondence on the subject, which appears to be for the most part typically suburban in character. A relieving note of distinction, in residence if not in thought or expression, is supplied by a lady writing from Mayfair, who signs herself Gertrude Wilkinson. Here is her contribution:—"The Briton boasts of love of Free Trade and Fair Play, and yet at this most perilous crisis our Government dares to

refuse to a man who is known far and wide as a great surgeon and a great healer the permission to heal—officially. He has cured thousands, and now offers to give up a large income to fit men to fight for their country. Shall it be endured that red-tape and prejudice prevent him?"

Mr. Barker. This is a very fair specimen of the hysterical balderdash, by publishing which the *Star* seeks to impress its readers in favour of Mr. Barker.

The pudding-brained nonentities who deal in this kind of delirium do not seem capable of appreciating the fact that if Mr. Barker is the heaven-born surgeon they would have us believe him to be, he would have no difficulty whatever in obtaining a surgical qualification. If he prefers to remain without a legal qualification, it is to be supposed that he has good reasons for this preference. An unqualified man has greater freedom and less responsibility than one who is qualified. There are several disabilities attaching to a qualification, that which forbids advertising for example. This is commercially a very severe one, so severe that there are many who consider it overwhelming. The suburban enthusiasts, who write to the *Star*, demand for Mr. Barker that he shall be given the best of both worlds, the narrow sanctity of orthodoxy and the broad free-lancing of heterodoxy. They might as reasonably demand for Mrs. Pankhurst the Archbishopric of Canterbury.

Medicine for Women. A NON-MEDICAL correspondent writes me a long letter, the gist of which is that it is all very fine for me to take up the cudgels on behalf of my own cloth, but that it is useless for me to

do so, as long as there are members of the profession who, whilst blowing their own trumpets in the lay press, "blow the gaff on the supposed nobility of our calling." In support of his rather vague position, he encloses an article which appeared in the *Westminster Gazette* on December 20th, entitled "Medicine for Women," by Dr. C. W. Saleeby, with the following passage underlined: "The public and not least the Child of Life are paying the price for the pitiful hostility (to medical women) of male members of the medical profession, in the palpable interests of the Calf of Gold, to which, however, no clause in the Hippocratic Oath is dedicated."

Unworthy Motives. This is not a very lucid pronouncement, but in so far as it means anything, it seems to suggest that the opposition of male doctors to the entry of women into the profession is a purely mercenary one; that the opposition is, in fact, based upon the fear of competition. If this is what Dr. Saleeby really means to convey to his lay readers he ought to be ashamed of himself. He must know perfectly well that no doctor expects to escape competition, and that every male would, in his own interests, rather have a female competitor than one of his own sex. But that is not all. Dr. Saleeby must also know perfectly well the "pitiful hostility of members of the profession" to their sisters, daughters, nieces and wards entering the profession is based not upon

monetary consideration but upon their own vivid recollection of the hardships and disillusionments inseparable from the student's curriculum; the mental strain, the physical fatigue, the revolting realities of the dissecting-room, the pathos of suffering in the wards, and the impressive nerve-shattering ritual of the operating theatre. Who, having himself suffered these things, and remembering them, would not prefer that his young women folk should take to some calling less exhausting in its apprenticeship and less exacting in its pursuit?

Medical Women. DR. SALEEBY tells us that he has for years advocated the "medical woman." If this is the kind of advocacy which he has brought to her support she may well pray to

be saved from such a friend. To impute mercenary and other unworthy motives to those who do not agree with you is a mark either of ignorance or weakness. In Dr. Saleeby's case it is certainly not ignorance. In a later passage in the same article the writer says: "On every ground, therefore, as a public practitioner, I now prescribe Medicine for Women." For individual women such a prescription may be a very good one; but thus to prescribe at large, without reference to individual needs and temperaments, is the way not of the qualified practitioner, but of the unqualified.

Qualifications. BUT the real inwardness of the article is revealed in the following passage: "In general clinical medicine, in obstetrics and gynaecology, and in the care of infants and children, women have sexual qualifications which often make them preferable to men on every score." It would be interesting to know what Dr. Saleeby means by the adjective "sexual" in this connection, and it would be still more interesting to be told what the "sexual" qualifications are, which render woman, as a doctor, superior to man "on every score." We are perhaps intended to infer that one of these qualifications is the stability of mental equipoise and added soundness of judgment which betoken menstruation; and that another is the combination of physical vigour, sweet reasonableness and philosophic calm, so characteristic of the menopause.

SINAPIS.

LANCASTER district farmers' sale for the British Red Cross Fund on December 15th resulted in a total of about £2,000, the largest sum yet taken in Lancashire. Six professional auctioneers were kept busy all day. Mrs. Briggs, the Mayoress, sold the first lot. Alderman Nuttall, Mayor of Blackburn, spent two hours in a heavy downpour of rain at Blackburn selling farmers' products for the Red Cross Fund. An egg sold for 82s.

Two motor ambulances, the gift of the women of Deptford to the British Red Cross Society, were formally presented to the Society by the Mayoress of Deptford at Goldsmith's College, New Cross, recently.

IN Greater London during the week ending December 18th 2,855 births and 2,068 deaths were registered. Allowing for decrease of population, these numbers are 582 below and 17 above the respective averages in the corresponding weeks of the previous five years.

CURRENT TOPICS.

Crawford Long and Ether Anæsthesia.

We publish in our present number a historical note by Dr. George Foy on Crawford Williamson Long, the discoverer of the use of ether anæsthesia in surgery. There is, we think, no longer any doubt that Long is entitled to the credit of priority over Morton in the introduction of ether as an anæsthetic agent. Long used the drug in a series of operations with satisfactory results, and he communicated the facts to his medical brethren. He was, however, a country doctor without influence or powerful friends, and his discovery attracted little attention. There is no ground for believing that Morton had ever heard of it, or that his discovery was other than quite independent. Morton, however, had the good fortune to interest Warren, and when the experiment proved a success, Morton—powerful and enlightened—was able to spread the knowledge of the new agent throughout the civilised world. But in the honour that is rightly due to Morton, the humbler and less famous Long must have his share. Not the least interesting part of Dr. Foy's article is that in which he shows the gradual evolution of knowledge of anæsthetic drugs, and the part played in that progress by his fellow-countrymen. Higgins, of Sligo, and Mrs. Beddoes, of Longford, prepared the way for Crawford Long, the grandson of a Donegal man.

The Probationer.

It is a matter for regret that so much of the probationary nurse's time should be occupied by the purely domestic work, frequently even having no direct bearing upon sick-room management. The mere distribution of meals, together with the tidying of wards, and arrangement of patients preparatory and subsequent to the daily visit of the clinical staff, demand the major portion of the day. Such time as is left is required for a hard earned rest. In this connection, the theatre and extern nursing staff come off best, being engaged for the most part in technical work. As a result of continual cleaning up and household work, many girls commencing their training quickly tire of their intended profession—not having an opportunity of seeing it from the more expert point of view. Above all, in a hospital which has numerous clinical clerks and surgical dressers, especially if these be keen, the nurses' share tends to degenerate into the mechanical giving of medicines and enemas—together with an automatic pulse or temperature plotting. It is, we know, largely unavoidable from an economic point of view—yet it might be possible to make the junior nurse more intimate with the purely medical side of the cases and thus enhance the interest of her own work, and her usefulness in the occupation she has chosen.

Symptomatic Treatment.

We have chosen this week for re-publication as our representative article from the recent American literature an article on Symptomatic Drug Treatment by Dr. Joseph Miller, of Chicago. It must be

admitted that our colleagues in America are somewhat more ready than ourselves to try the new and cast the old aside. Their minds are fresher, less conservative, and we think, on the whole, less critical. In this matter of symptomatic treatment the Americans are less habit-bound than we, and it was not without significance that in the compilation of a large book on treatment by distinguished American editors a few years ago the chapter on drug treatment was committed to an English physician. Dr. Miller's article, which we print this week, is an attempt to face the question of how far treatment of symptoms is sound and just, and this is the essential point at issue. Many of our drugs influence symptoms readily enough, but how few exert much influence on the course of the disease? Moreover, suppression of the symptoms, although comforting to the patient, may be very harmful to him. The question has never been fairly faced as yet—and it is so easy in practice to relieve a symptom. Dr. Miller makes one suggestion which, if it were possible to carry it out, would have a high educative value. It is that students should be given an opportunity to observe untreated cases side by side with those that are treated. If this were possible, it would go far to do away with the *post hoc ergo propter hoc* inference which is the basis of so many of our therapeutic conclusions.

Institutional Statistics.

SUCCESSFUL returns are the legitimate aim of all institutions, medical and otherwise, but there should be no sacrifice of truth or principle in order to further a more auspicious result. In our experience, there is occasionally an anxiety to commit cases presenting an obviously hopeless prognosis to the care of relatives, in order to avoid their death being directly associated with the institution in question. Inasmuch as no more could be done for the sufferer, it might be even regarded as a benevolent act to allow the final days to be spent in the company of those near in blood; but it is quite evident that the yearly return in such a case must be seriously vitiated should any substantial number of such cases have occurred, and also that no sound inference could be drawn. Again, in institutions possessing medical officers, although not themselves hospitals, similar instances have occurred, where inmates have been sent long and injurious journeys to some professed hospital when they would have been more advantageously allowed to remain where they were. Such procedure in a condition of cerebral hæmorrhage, for example, is both harmful and futile—yet in one case we can call to mind death ensued an hour or two after transference to the local infirmary, the cause of death being subsequently determined as extensive blood-extravasation of the brain. We are far from suggesting that any extensive practice of the kind exists—but even isolated instances are surely not to be commended.

Intravenous Injections of Sugar.

In the *Journal of the American Medical Association*, Messrs. R. T. Woodyatt, W. D. Sansum, and R. M. Wilder describe an ingenious device whereby continued, prolonged, and accurately timed

and measured intravenous injections can be made. By this means sugar solutions can be injected into man or animals at any desired rate and for any period of time, and the actual sugar tolerance and utilisation determined with the factors of absorption entirely eliminated. Studies made with this *technique* showed that a seventy kg. man could utilise about 63 grams of glucose an hour, which is equivalent to 652 calories an hour, or 6,048 calories a day. Intravenous nutrition is, therefore, possible by this means. The normal human glucose tolerance was found to be about 0.85 grams an hour per kgm. of weight when given slowly by a vein. The idea that the glycogenic function of the liver is essential for the utilisation of glucose, or that it is essential as a barrier to prevent the loss in the urine of absorbed sugar, has been proved incorrect by these experiments. The idea that any large quantity of sugar given by vein always causes diuresis and glycosuria was also disposed of. In Graves's disease the intravenous tolerance was found to be as low as 0.65 grams per kgm. an hour. The tolerance limit for *lævulose* was found to be about one-sixth that for glucose; for galactose it was even less; and for lactose it was zero. When glucose was given intravenously at a rate faster than 0.9 gram per kgm. an hour, glycosuria appeared and later diuresis. The glycosuria soon reached a level and remained at that point during any rate of injection, which point depended on the rate of administration. By comparative tests it was shown that the maximum rate of sugar absorption after oral administration did not exceed 1.8 gram per kgm. an hour. Intense diuresis could be produced by the injection of amounts of sugar in excess of the tolerance, and the dangers of dehydration or hydræmic plethora then made their appearance. The clinical applications of this method are: The abstraction from the body of any desired quantity of water and the flushing of the body with any desired and safe amount of water.

Walsall Facts and Fables.

WE congratulate the panel doctors of Walsall on their champions in the local Insurance Committee. We read that at a meeting of this Committee, Dr. Hawley drew attention to statements made by a member, Mr. G. Power, who is also secretary of the Midland Leather Trades' Federation, at a meeting of the local Friendly Societies' Council to the effect that owing to the great numbers of patients which local doctors had on their books insured workers were unable to get proper attention; that in some instances persons had to wait outside surgeries in queues, and had been kept waiting three or four hours before they received attention. Dr. Hawley said he denied that there was the slightest foundation for any of these charges. As a matter of fact, local doctors had had less surgery work since the war started. Following this, Dr. O'Meara said if such things were going on Mr. Power should have complained to the Insurance Committee. As a member of the Committee his attitude was disgraceful, and he ought not to continue to be a representative of the insured workers. Mr. Power replied that the object of the medical profession was to "gag" people, and so prevent them from expressing their opinions. He added that as the matter had been taken up by the Friendly Societies' Council he could not withdraw the charges without consulting them. A resolution was carried asking that the charges should either be withdrawn or substantiated. Mr. Power voted for the resolution, remarking that it was perfectly satisfactory to him.

Mr. Power's attitude is typical of a class—unfortunately large—which poses as the protector of the poor insured workers. When challenged, he takes refuge behind a partisan Council which

is supposed to be investigating his charges. Mr. Power, of course, made his original statement to a Friendly Societies' Council, where he probably felt sure of gaining cheap applause by "slanging the doctors," and where he felt equally certain of no contradiction. Dr. O'Meara is perfectly justified in characterising Mr. Power's attitude as disgraceful. It was that gentleman's duty as a member of the Insurance Committee to bring his "facts" at once to their notice, when a proper inquiry could have been instituted. If Walsall workers have to stand in queues and wait three or four hours before they receive attention, Mr. Power could without difficulty have produced a cloud of witnesses, and we know his type well enough to feel sure he would have missed no possible opportunity of so doing. He prefers to tub-thump in the kind of gathering well known for hostility to the medical profession, where froth is mistaken for fact. Dr. Hawley and Dr. O'Meara deserve the thanks of their brethren for their castigation of the secretary of the Midland Leather Trades' Federation.

Mixt. Diabol.

IT is not often that we find in the *Times* anything which is humorous from a purely medical point of view. The following, which recently concluded a purely medical article in a light vein, is an agreeable exception. We have all had our favourite recipes for this particular dissuador; there has even been a fiendish rivalry among different schools for the production of the finest brew. When we last inquired into the matter the Bart's vintage was said to be the best.

"MIXT. DIABOLICA."

"But we do think we know how to deal with the 'skrimshanker.' We give him every chance; we even have a consultation over him, and then, if we are quite certain in our mind, we put him on our celebrated Mixt. Diabolica. Its composition is, and must remain, a secret, but its action is certain and speedy. It is almost as miraculous as the Holy Water of Lourdes.

"To show you what it can do, it cured in *one dose* a man who complained of deafness and blindness, pains in the back and side, pneumonia of eight week's standing, inability to feel his feet or stand, and a few other trifles. He lay on his cot, a helpless wreck for hours before, but after one dose, all he wanted was water to drink, and to get back to his regiment as quickly as possible. It is 'some' medicine!"

PERSONAL.

SURGEON DOUGLAS MOODY, R.N., lost his life through the explosion on board the *Natal*. Amongst those saved is Surgeon E. S. Tuck.

CAPT. J. D. BUCHANAN, one of the leading surgeons of Brisbane, has died of wounds. He served in a Field Ambulance of the Australian Force.

DR. J. D. MURPHY, temporary Second Assistant Medical Officer at the Marylebone Infirmary, has obtained a commission in the Navy, and has resigned his appointment under the Board of Guardians.

DR. J. BELL FERGUSON, Tuberculosis Officer of York, was desirous of accepting a commission in a military sanitary corps. York City Council has refused to release him. It was stated that the death-rate of the city was almost equal to the birth-rate.

STAFF-SURGEON ALFRED OSWALD HOOPER, M.B., was lost in the explosion on board H.M.S. *Natal* on December 30th. Dr. Hooper was Assistant House Surgeon at Leicester Royal Infirmary before joining the Navy.

FRENCH CLINICAL LECTURE

ON

CHRONIC RECURRENT TETANUS.

By ALBERT MOUCHET, M.D.,

Surgeon to the Paris Hospitals, Chief Surgeon to the Auxiliary Hospital No. 26, at Orleans.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE tetanus with which most of us have become familiar since the war broke out, especially during the early months, was acute or hyperacute tetanus. For that matter it is highly probable that we shall in future hardly ever be called upon to deal with this complication now that the medical service at the front is adequately provided with anti-tetanic serum and preventive injections are methodically employed.

Though extremely rare, chronic recurring tetanus deserves our attention. It is not so easy to recognize but it is also more amenable to treatment, since its existence, dependent on the retention of a foreign body in the tissues, disappears as soon as this is extracted.

Out of a score of cases of tetanus which have come under my notice in my own "formation" or elsewhere, I have on two occasions been called upon to deal with cases of chronic recurring tetanus. One of them was under the care of Dr. Auboyer, and as he has published it in the *Paris Medical* I need not go into details.

The other case was the following, and its course was sufficiently interesting to make it worth recording. "J. C.," age 23, was wounded on October 28th, 1914, by a fragment of shell, which buried itself in the left supra-spinous fossa, making a not very big wound with somewhat irregular edges. He was transferred to Pithiviers on November 1st, under Dr. Bazor. As the wound, though septic, was not suppurating much, it was not thought necessary to open it up, simple antiseptic dressings being applied. His general health was excellent, appetite normal, no temperature.

After the ninth day (13 days after the infliction of the wound) Dr. Bazor noticed that the patient's head was tilted towards the wounded side and that he had some difficulty in straightening it, the effort to do so moreover was painful. The patient also complained of more or less continuous pains associated with periodical exacerbations. These symptoms led Dr. Bazor to give him an injection of anti-tetanic serum (20 cc.).

The attacks of pain became more marked and more frequent, the bent attitude of the patient looked more and more like a contracture which became more pronounced when the pain came on, the pulse at the same time rising to 100-110 a minute. He perspired copiously, though the temperature remained normal. As the diagnosis of tetanus was pretty certain the patient was isolated and placed under observation.

The contractures became more pronounced and trismus supervened. The temperature, 99° in the morning, did not exceed 99.9° at night. Cerebral excitement well marked: restlessness, hallucinations, delirium, insomnia. The classical treatment with massive doses of chloral and morphine was instituted. He was also given a second injection of serum (10 cc.). Little by little the attacks of contracture diminished, the delirium ceased, the pulse became less rapid and by December 25th the patient appeared to be well. He was then sent to a convalescent home.

The wound in the right supra-spinous fossa was still suppurating slightly and a few splinters of bone came away in the dressings. During the rest of the month (January) his local and general state remained satisfactory, though the pains persisted as well as the stiffness of the shoulder, which the patient was unable to overcome.

On February 1st he was sent back to the hospital with a fresh outbreak of tetanus, trismus re-appeared to some extent and the contractures returned, especially on the left side, with pleurothotonos, wild delirium, rapid pulse, etc. An injection of 10 cc. of serum was again given and chloral was administered.

The X-rays showed a piece of shell in the sub-clavicular fossa, between the thoracic wall and the anterior surface of the scapula, moving with the latter. Consulted at this juncture by Dr. Auge, I strongly advised its removal, but circumstances precluded the operation being performed until February 7th, when the patient was in the midst of an attack of tetanus, pulse 125. Under chloroform I opened up the fistulous wound and removed the foreign body without much difficulty. It measured one centimetre in width and four in length, and with it came away fragments of cloth. Bacteriological examination revealed the presence of a few tetanic bacilli.

For some days after the operation the patient's state remained unchanged, though healing was proceeding nicely. The temperature rose to 102.2° F. night and morning for six days. After the tenth day the temperature and pulse began to improve and the delirium subsided. On the other hand, the contractures began to lessen directly after the intervention, and the trismus disappeared almost at once. The laryngeal spasms persisted for another ten days, preventing his taking ordinary food. On February 29th the patient had completely recovered, but the operation wound did not finally heal until March 10th.

Certain practical lessons are to be drawn from the history of this case. Of course, it would have been better if the patient had been given an injection of serum at once, directly after being wounded, and not having had it he contracted tetanus. But as the fragment of shell was left in the sub-scapular fossa he would still have been exposed to an attack of late tetanus after the antitoxin had been eliminated or its neutralising action had become exhausted, because fresh toxins might have been secreted by the tetanic bacilli embedded in the *débris* of cloth adhering to the bit of shell.

It is easy to understand that it was not thought necessary to inject serum for such a small wound, but, having learned by experience of such cases, the risk of delayed tetanus running a slow course, I hold that every wound inflicted by a projectile calls for the injection of serum, especially when caused by splinters of shell, which invariably carry in with them bits of clothing. This remark applies also to wounds with only the aperture of entry.

In some instances the patient tells us that he has been injected at the front, but in most instances he knows nothing about it. In any case, unless it is

entered on his hospital ticket that an injection has been made, the surgeon in the rear should make a practice of giving it, though, as a measure of prudence, he may begin by injecting a small quantity should the patient think he has already had one.

Another lesson is to be drawn from this case. This soldier's wound seemed insignificant and had been duly cleansed; but, insignificant though it seemed, it ought to have been opened up in the absence of any information as to the nature of the projectile. We know well enough that tetanus only too often follows apparently trifling wounds, precisely because they are small and are therefore neglected. Antiseptics cannot be brought into contact with the tract, so that when any tetanic bacilli happen to be present they find in this closed wound very favourable conditions for their proliferation.

If in this case the wound had been freely opened up, the surgeon might, even in the absence of radioscopic data, have come upon the projectile and cloth *débris* carried in therewith. The opening up would not only have been prophylactic, but also curative. However this may be, the laying open would have allowed antiseptics free access to the recondite corners of the tract, and so hindered the proliferation of pyogenic microbes and *pari passu* of tetanus.

This case reinforces and confirms the axiom that every wound by projectiles in war when seen to be infected (however trifling they may seem) are to be freely laid open. This is a fundamental rule which is to be strictly observed and acted upon, a point upon which we cannot too strongly insist. The subject runs no risk—on the contrary, in most instances he stands to gain a good deal. Independently of the serum injection, the value of which has now been placed beyond question, free early opening up and thorough disinfection of the wound unquestionably plays a foremost part in averting tetanus.

There is one other detail in the case that deserves attention—viz., the presence of stiffness of the shoulder on the wounded side, constituting the first symptom of tetanic contracture. Although trismus and dysphagia are, as a rule, the earliest symptoms of tetanus, we are justified in attaching great importance to "stiffness" in the neighbourhood of the wound. If we then examine the wound attentively, we find that it is not merely a reflex contracture due to the proximity of the wound, but a sign of tetanic intoxication that is running its course.

Lastly—and this is the great lesson to be drawn from this case—from the moment that tetanus makes its appearance in a case in which the projectile is still in the tissues, it must, if possible, be extracted at the earliest possible time. For this purpose early radioscopic examination is indispensable, after which no time should be lost.

In the present case, had the projectile been extracted at the onset of the disease, the patient would not have been exposed to the risk of a relapse as soon as the neutralising effect of the injection of serum had passed off. This relapse was the more to be apprehended in presence of the unremoved projectile, seeing that the wound had not completely healed. The soldier was allowed to leave as convalescent with a stiffness of the shoulder, which ought to have suggested the possibility of tetanic contracture.

The injection of anti-tetanic serum, free opening up of the wound, and extraction of the projectile constitute the tripod therapeutics on which our treatment of such wounds must be based.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Tom A. Williams, M.B.,

C.M.Edin., Lecturer on Nervous and Mental Diseases, Harvard University, Washington; President, Washington Society of Nervous and Mental Diseases; Foreign Correspondent, Member of the Society of Neurology, Paris, etc.; Neurologist, Freedmen's Hospital and Epiph. Dispensary, Washington. Subject: "The Management of Functional Nervous Affections: Modern Methods Illustrated."

ORIGINAL PAPERS.

SOME BRITISH MEDICAL MEN OF LETTERS.*

PART II.

By W. H. MAIDLLOW, M.D., F.R.C.S.

SIR THOMAS BROWNE, the author of "Religio Medici," was born at Cheapside 14 days after the exposure of Guy Fawkes. From Winchester College he proceeded to Pembroke, Oxford (incidentally also Johnson's), thence to study at the great medical schools of Montpellier, Padua, and Leyden, which granted him his degree. He travelled over a good part of Europe growing in knowledge of men and things. "For my own part," he writes, "besides the jargon and patois of several provinces, I understand no less than six languages, yet, I protest, I have no higher conceit of myself than had our fathers before the confusion of Babel." On his return to England, he settled at Halifax, where he began his immortal work; but Halifax was not responsive, and he finally settled at Norwich, which town he adorned till he died. The Pope put "Religio Medici" in the "Index Expurgatorius." He certainly was no bigot—"At the sight of a cross or crucifix I can dispense with my hat, but not with the thought of my Saviour; I cannot laugh at the fruitless journeys of Pilgrims or condemn the miserable condition of Friars. For though misplaced circumstances, there is something in it of devotion. I could never hear the Ave Maria Bell without an elevation or think it a sufficient warrant because they erred in one circumstance for me to err in all."

Of his children, one son became physician to Charles II. and President R.C.P., and his son was likewise a physician. Of his other children, a daughter is the ancestor of the present Earl of Buchan. His son Tom was killed in the Dutch Wars. Sir Thomas died 1682 of some sort of colic, associated with influenza, and, like Shakespeare, on an anniversary of his birthday, apparently as anxious as was Shakespeare about his bones! Less lucky, however, for in 1840 his skull was "knaved" from his grave, apparently during some repairs. The skull was shown at the Norwich Hospital, but, I believe, has been re-interred at the instance of the British Medical Association. I make a few more quotations:—"Let me be sick myself if sometimes the malady of my patient is not a disease to me. I desire rather to cure his infirmities than my own necessities. Where I do him no good methinks it is no honest gain, though I confess it to be the worthy salary of our well-intended endeavours. I am not only ashamed, but heartily sorry that besides death there are diseases incurable; yet not for my own sake, but for the general cause and sake of humanity, whose common cause I apprehend is mine own. . . . There are not only diseases incurable in Physicke but cases indissoluble in Laws, vices incorrigible in Divinity."

Compare his Evening Hymn, in which he calls his "dormitory," his "Colloquie with God" with that of Ken, who came to Winchester after him, where he wrote his better-known "Evening Hymn" for

* A paper read before the Ilminster Literary Society.

Wykehamists. Browne takes "no other Laudanum to sleepe," "after which I close my eyes in security, content to take my leave of the sun, and to sleep until the Resurrection."

He says:—

"Sleepe is a death, O make me try
By sleeeping what it is to die,
And down as gently lay my head
On my grave as now my bed."

Ken has:—

"Teach me to live that I may dread
The grave as little as my bed."

JOHN LOCKE.—My next is a philosopher par excellence, a Somerset man born unexpectedly at Wrington in 1632, the famous John Locke. Westminster School, under the headship of the well-known Busby, was his public school, and after that came Christchurch, Oxford. We find him in comparative youth ridiculing the notion that public school life at all fits a boy for any subsequent occupation. He maintains the impossibility of proper individualisation. Perhaps he was not a success at Westminster. He became M.A. Oxford in 1660, and may have taken some medical degree there. Anyhow, he became the family physician of Lord Ashley, afterwards Earl of Shaftesbury, who seems to have had a suppurating hydatid cyst.

He had a good deal to do with the education of two subsequent earls, and probably arranged the marriage between the third Earl and Lady Dorothy Manners on eugenic lines. At 40 he got some sort of chronic bronchial asthma, gave up medical work (although in 1675 we find he attended, for neuralgia, the Duchess of Northumberland with more success than the French doctors), and took up philosophy more keenly. On his return to England from France, after some diplomatic business in 1679, he got involved in political intrigues, mixed up with the Monmouth plot, and fled to Holland, to return with Queen Mary in 1689. William III. tried to persuade him to become his Ambassador in Prussia, but his poor health prevented him; he said he could not "*drink* sufficiently." He died peacefully, aged 72, in the circle of such great men as Sydenham, Newton, Dryden, Cudworth and Hobbes.

No educationalist is complete without a knowledge of his "Thoughts concerning Education," and every doctor should read his "Human Understanding." He sums up his philosophy of life thus:—

(1) It is a man's proper business to seek happiness and avoid misery.

(2) Happiness consists in what contents the mind—misery is what disturbs it.

(3) Care must be taken lest we prefer a short pleasure to a lasting one, otherwise it is plain we cross our own happiness.

This last clause prevents the "Omar Khayyam" view:—

"Oh plagued no more with human or Divine,
To-morrow's tangle to itself resign."

The physicians in the times of William III., Anne, and the early Georges, took prominent parts in the politics. Thus we have amongst pronounced Whigs Sir R. Blackmore, physician to William III., also a voluminous and boresome poet; Richard Mead, Arbuthnot and Garth. On the Tory side we have especially Radcliffe, famous alike as a physician and partisan, the founder of the Radcliffe Library, a scholarship, and the Infirmary at Oxford. There is a story told of Brocklesby, of whom more anon, how he was so engaged in a wordy fray with the Duchess of Richmond's butler that he quite forgot he was there to see a patient. Poor Anne must have had a rather trying death: Radcliffe refused to do what he could, and Mead wanted her to live only long enough for political purposes.

During these reigns most of the leading physicians were men of letters; in fact, it was probable their literary association fed their medical fame. Their names appear in most of the text-books of English literature, but I suppose that with the exception of Goldsmith they are neither read nor remembered, or even heard of by the ordinary reader. Thus we have a group from 1700 to 1760 contemporary with such men as Dryden, Addison, Pope, Steele, Gray, Swift and Samuel Johnson. They were all more or less associated with the two clubs, the "Kitcat" and the "Literary Club," of which Goldsmith was an original member. I believe these literary clubs still live.

These men are of too remote an interest to justify more than a passing mention. Sir SAMUEL GARTH, M.D. Cantab., was Dryden's physician and attended George I. To him we owe a proper burial for Dryden and a great funeral oration for that poet. During the oration he fell into a tub on which he was standing! His death was somewhat like that of Rabelais. He murmured to his physician, "I wish the ceremony of death were not so long," and asked to be allowed to die a natural death. He was perhaps the most witty of the members of the Kitcat Club; his patients possibly valued his bon-mots more than his prescriptions.

Pope wrote of Garth after his death: "If ever there was a good Christian without knowing himself to be so it was Garth." The same author says: "He was a Whig without a rancour and a bon vivant without selfishness." Garth was knighted with the sword of Marlborough. He died in 1719, and is buried at Harrow.

Thus Johnson: "I think Arbuthnot the first man amongst them" (the eminent writers in Queen Anne's time). "He was an excellent physician, a man of deep learning and of much humour."

JOHN ARBUTHNOT came from the North. Before settling in London he tried practice at Dorchester, became physician to Queen Anne, was the great friend of Swift, and of Pope, who loved him. Amongst his other writings, he is famous for the history of "John Bull," which expression he coined. He figures John Bull as a clothier. "What is the time?" said Queen Anne one day. "Whatever it may please your Majesty," answered the court physician.

RICHARD MEAD is another example of a man prominent in his times and centre of a learned group who is now largely forgotten. He was physician to Queen Anne with Arbuthnot, and was greatly instrumental in the establishment of the Hanoverian Monarchy by insisting that Her Majesty would soon die, thus frustrating the Jacobites, who wanted more time for the Restoration. He is said to have made as much as £1,000 a year. He made no great contribution to general literature, but was the companion, friend and benefactor of many great writers. His "*Medica Sacra*" is an interesting medical curiosity. He had dancing lessons at the age of 70.

Then in the reign of George II. we have TOBIAS SMOLLET, who died in 1771, was for some time surgeon on a battleship, and took part in the battle of Cartagina. His great work, "*Roderick Random*," is founded on his life, and he satirises Akenside in "*Peregrine Pickle*."

JOHN MOORE was a physician of much eminence, forgotten because he made no great contribution to literature, except his now little read "*Zeluco*." His claim to fame rests chiefly on the fact that he was the father of that great General whose masterly retreat to Corunna saved the situation—a retreat comparable to ours from Mons in the face of vastly superior forces. Moore lived through the French Revolution at Paris, where he was travelling with

his patient Lord Lauderdale. His account as an eye-witness is to my taste better than the more verbose story of Carlyle's.

MARK AKENSIDE.—Another royal physician to George II. and well-known litterateur was Akenside, second son of a butcher of Newcastle-on-Tyne, who, originally destined for the Presbyterian pulpit, became M.D. of Edinburgh in 1745. Akenside must have been a dreadful man, one of that irritable race of scribes which seems to have corns wherever you tread, and his mixture of literature and medicine must have been truly dangerous. He was ambitious to be great in both spheres, and certainly did get some fame in his day. He died more feared than loved, poor and a bachelor, aged 49. His great work is undoubtedly "The Pleasures of the Imagination," which gained the approbation of Pope.

Johnson wrote of it: "His images are displayed with such luxuriance of expression that they are hidden; they are found fantastically under a superfluity of dress. The words are multiplied until the sense is hardly perceived. Attention deserts the mind and settles on the ear." You will find "The Pleasures of the Imagination" maintains the same unvarying level—a high one, but monotonous. I quote as an example from "The Pleasures of the Imagination":—

Akenside: "Pleasures of the Imagination" (Book I., p. 11, line 183).

Disdains to rest her heaven-aspiring wing
Beneath its native quarry. Tired of earth
And this diurnal scene, she springs aloft
Through fields of air; pursues the flying storm,
Rides on the vollied lightning through the heavens,
O'er yoked whirlwinds and the northern blast,
Sweeps the long tract of day

Till every bound at length should disappear
And infinite perception close the scene.

(We wonder almost what *did* happen to the high-born soul!)

These lines bespeak his discomfort of bachelorhood (Ode IX., Bk. II.):—

"Though the day have smoothly gone,
Or to lettered leisure known,
Or in social duty spent,
Yet at even my lonely breast
Seeks in vain for perfect rest,
Languishes for true content."

Kipling has some lines about "He travels the fastest who travels alone." It is possible, however, Akenside might have been happier married.

RICHARD BROCKLESBY deserves a place in the Temple of Fame if for no other reason than that he was the friend, benefactor and the frequent medical adviser of Dr. Samuel Johnson, the giant of English literature. He is interesting to us people of Somerset also in that he was born at Minehead and was the uncle of another great man, Dr. Thomas Young, of Milverton, near Taunton. It is to Dr. Young that we owe in a large measure a knowledge of proper spectacles for astigmatism and pioneer work in deciphering the hieroglyphics of the Rosetta Stone. Like many another great physician, he was almost unknown to the general public.

Brocklesby was born in 1722 and educated at Kildare, where he started his friendship with Burke and Buckle. He took his degree at Edinburgh and Leyden and became a Fellow of the Royal College of Physicians. In 1758 he was Surgeon to the English army fighting in the wars of Frederick the Great. In 1763 he returned to London, where he received all sorts of honours. He gave as the Harveian Oration a panegyric on Nathaniel Hodges, one of the many doctors who remained at their posts during the Great Plague of London.

(You can read of Hodges in Harrison Ainsworth's "Old St. Paul's," a book which should be read in conjunction with "Peppys' Diary.") Brocklesby was both generous and learned, a benefactor of Burke and Johnson, and lived in the most illustrious circle known in the history of English literature. He is the author of an interesting little book on the "Regular Use of Music in Medicine," and was one of the first of those who dealt with the importance of hygiene in the army. One day Johnson, ill and depressed, quoted "Canst thou not minister to a mind diseased?" Brocklesby pleased his patient by readily answering, "Therein the patient must minister to himself." Verily to have been a benefactor to three such men as Johnson, Burke and Young (to whom he left his fortune), to have shared their conversation, and to have enjoyed their esteem, is perhaps the highest distinction which has ever been attained by any member of the Army Medical Service.

The next group of men were hardly properly qualified doctors, and they have little claim for any medical attainments. I speak of George Crabbe, Keats, Goldsmith and Francis Thompson. The first of these, CRABBE, was born at Aldeburgh in 1754. He was the eldest son of a salt master. At the age of 18 he was apprenticed to a surgeon near Bury St. Edmunds, sharing a bed with the stable boy. (Up to the middle of last century, the future doctor was always apprenticed to a man in general practice—a plan not without its advantages, in that he was not launched *quite* raw on to the long suffering public!) We hear of him next at Woodbridge, under a Dr. Page, and in 1775 he published his first poem, on "Inebriety."

At Woodbridge he probably met Sarah Elmy, his future wife. He saved enough money to start work at Aldeburgh, and was appointed surgeon to a militia regiment; but I do not think he ever properly qualified. Not flourishing there (probably the somewhat primitive inhabitants were too healthy), he went, nearly penniless, to London, and after much anxiety and nearly suffering the fate of Chatterton, got under the notice of Edmund Burke, who had him appointed to the post of chaplain to the Duke of Rutland. From this time he entirely gave up medicine, became an excellent clergyman, a keen botanist, and a celebrated poet, living happily with his Sarah at Woodbridge till his death in 1832, leaving one son, who wrote his life.

Crabbe's strength lies in his characterisation and epigram. He has been well described as a poet to the poor; his own youthful hardships put him in sympathy with the distressed in mind, body and estate. Examples (Vol. II., p. 344):—

"No! let the guiltless, if there such be found,
Launch forth the spear and deal the deadly wound.
How can I so the cause of virtue aid
Who am myself attainted and afraid?
Yet as I can, I point the powers of Rhyme
And, sparing criminals, attack the crime."

The then parish doctor (Vol. I., p. 14):—

"But soon a loud and hasty summons calls.

With looks unaltered by the scenes of woe,
With speed that entering speaks this haste to go,
He bids the gazing throng around him fly,
And carries Fate and Physic in his eye.

(He) first insults the victim whom he kills,
Whose murderous hands a drowsy bench protect.
And whose most tender mercy is neglect."

Quacks (Vol. II., p. 95):—

"But now on Quacks and Gamesters, and they play
With Craft and Skill to ruin and betray:
With monstrous Promise they delude the Mind
And thrive on all that tortures Human kind."

Old Nurses (Vol. II., p. 100):—

"Then the good Nurse (who, had she borne a Brain,
Had sought the cause that made her Babe complain)
Has all her efforts, loving Soul! applied
To set the cry and not the cause, aside;
She gave the powerful sweet without remorse
The sleeping cordial—she had tried its force;
The Infant, freed from pain,
Rejected Food—but took the Dose again."

His verse is conventional in the manner of the eighteenth century, correct, but with little grace. He imparted into English poetry a note that still has influence—realism. He wrote about real things, not of nymphs.

(To be concluded in our next.)

SOME REMARKS ON MENTAL HYGIENE AND THE PRE- VENTION OF INSANITY.*

By CAMPBELL MEYERS, M.D., M.R.C.S. ENG.,
L.R.C.P. LOND.

THE Provincial Inspector of Prisons and Public Charities states in his latest report that on October 31st, 1914, exclusive of the insane patients in the Homewood Sanitarium, at Guelph, there were in the Hospitals for the Insane of the Province of Ontario, 5,986 insane persons.* The total population of this Province, as shown by the last census, is 2,519,907. Hence one person in every 420 of the entire population of Ontario is certified insane. Moreover, the number of patients in the hospitals for the insane is greater than the number in the general hospitals of the Province. The Provincial Inspector of General Hospitals and Charitable Institutions states in his last annual report that on September 30th, 1914, the number under treatment in these institutions was 4,654. Hence 1,332 more patients were under treatment at this period in the hospitals for the insane than there were under treatment from all other diseases in all the hospitals of this Province, including the sanatoria for consumptives. This fact alone clearly indicates the importance and magnitude of the subject. The cost to the Province for the maintenance and capital expenditure of the hospitals for the insane in 1914 was \$1,704,699.48, being about one-sixth of the total provincial income.

This appalling and ever-increasing number of insane is surely a subject for careful consideration, and renders the prevention of insanity one of the most important of the humane and economic problems which are before the people of this Province to-day. While a large proportion of the number of admissions to hospitals for the insane are now discharged as more or less completely recovered, there still remain in these hospitals a large proportion in whom the sunlight of reason, and all enjoyment of life, is for ever gone—a vegetative existence in which often apparent physical health is combined with a single defect which produces a result sadder than death. Had the development of insanity been averted, the havoc wrought by the storm of the developed attack on the brains of these individuals would never have been experienced, and the mental integrity never been affected.

The mental suffering in insanity, especially during the early stages of the attack, has been justly said to be unequalled by that of any other disease to which humanity is heir. Nor is the suffering borne by the patient alone, since the relatives and friends must bear a profound grief—often over a prolonged period—when their sympathies and their powerlessness to afford either comfort or assistance makes them devoutly hope,

for the patient's own sake, that the physical remains of life itself might be removed.

From an economic point of view the loss to the state is tremendous. The expense of treatment and maintenance is great, extending as it does for some of these patients for over fifty years. More important still, however, is the loss to the state of the individual's capabilities for good and useful work, whatever walk of life he may have previously occupied—a loss which, morally, mentally and financially, it is impossible to estimate. If these facts only had to be considered, the question of the prevention of insanity would merit the most careful thought by all classes of the community.

Much more serious, however, than the appalling number of certified insane at present under treatment in the provincial hospitals is the fact that at least an equal number is each day steadily progressing towards the boundary line of insanity or passing completely over it, while practically no effort is being made to prevent this dire calamity. In other words, instead of the proportion of one to four hundred and twenty, as stated above, as being confined in the hospitals for the insane, there are at least another one in four hundred and twenty of our population who are daily nearing the same disaster without a single hand being extended to help them. (It is to be noted, moreover, that neither the number of the insane in the other provincial institutions, nor the large number of insane in this province who are not there confined, are considered in this connection.)

While the treatment of the insane has advanced by leaps and bounds during the past twenty-five years, no real assistance has been offered to prevent the full development of the disease, and once this has taken place, no matter how skilful the medical aid may be, the restoration to mental health is, at best, liable to be only more or less complete. True, the hospitals for the insane have opened their doors to voluntary patients, but the fact remains that, with rare exceptions, the patients will not decide to enter into these surroundings and associations—a decision, moreover, which is perfectly natural—until the onward progress of their disease leaves no alternative and they simply drift onwards with the irresistible current to the inevitable whirlpool. It is, therefore, clear that if success in treatment is to be obtained for those liable to develop insanity, it must be in different surroundings and with different methods and associations than those in which the insane are treated.

Can insanity be prevented?

The answer is an emphatic affirmative in a very large proportion of the patients. How can this result be best accomplished? The answer here is by two methods, which may be described as (1) General and (2) Special. The former relating to general mental hygiene in the development of the individual, and the latter relating to the active treatment of the patient when symptoms of his condition are beginning to develop.

The general methods to be employed for the prevention of insanity comprise the upbringing of the child, especially in regard to its normal development; a wise degree of education which comprises the avoidance of over-education in unsuitable subjects; a close observance of the laws of eugenics, especially the intermarriage of those exhibiting any mental weakness, or pronounced nervous affection, either in themselves or their forebears; the avoidance of alcohol; the prevention of syphilis (the two latter being especially prone to produce insanity); the cultivation of sound physical health and development by out-of-door sports; and the avoidance of pampering and self-indulgence, which are so prevalent in this twentieth

* *Canadian Journal of Medicine and Surgery*, November, 1915.

century: in short, by the development of those qualities, both physical and moral, which tend to the promotion of the best possible health, in accordance with the rules of mental and physical hygiene.

The special methods are applicable to the earlier stage of the developing disease, and include the steps necessary to obtain proper medical treatment for the condition.

In order to explain how prevention is best accomplished at this stage it is necessary to state briefly, and in a very general way, what class of insanity is most amenable to prevention, and then, what symptoms are to be found which indicate a danger of the full development of the disease.

It must be clearly understood that insanity rarely begins suddenly in ordinary life. The early symptoms in many cases are overlooked, or ascribed to other and especially physical causes, so that in those cases where the outbreak of active insanity is thought to have been sudden, a careful examination of the preceding nervous symptoms would clearly show that, in the large majority of such cases, the disease had been coming on, not only for weeks, but more often for months. Moreover, the advance of modern medical science enables a competent physician to foretell the outbreak of insanity often for weeks in advance, with at least as much certainty as that of any other form of disease. From this it will be readily understood that the outbreak of insanity is often preceded for weeks or months by symptoms which are commonly described as nervous, and the patient during this period is suffering from so-called neurasthenia, or nervous exhaustion. This by no means implies that all patients suffering from neurasthenia do, or will have, an attack of insanity. On the contrary, it is only when this diagnosis has been made that the fear of such a result may be considered, depending entirely, as it does, on the nature, the intensity, and the grouping of the symptoms. In other words, while neurasthenia frequently exists without any actual danger of insanity, insanity is rarely present in ordinary life without preceding neurasthenic symptoms, often of long duration. (An exception is found in the present war, where the mental strain and the shock of shell fire, etc., has been so great that mental derangement is often sudden in its onset.) It must also be carefully remembered that once insanity is fully developed it is too late for preventive measures, and that treatment in a hospital for the insane becomes generally imperative. Hence, treatment in an early state, when the symptoms are those of nervous exhaustion not only will, in the majority of cases, avert a developing insanity, but thus also obviate entirely the necessity for asylum treatment. Again, there is no doubt that the strain on the mental faculties of an individual who is obliged to pass through an attack of insanity, is liable to leave him—even when discharged as recovered—with more or less mental deterioration, so that he would be considered "not the man that he was." This unfortunate result would also have been obviated and the development into insanity been prevented by early treatment.

It must not be overlooked that insanity is a definite disease, having its origin in the higher centres of the brain, which is the chief organ of the nervous system, and that its location here is liable, especially in the early stages of the disease, to influence any or all of the functions of the various internal organs, since these depend primarily upon the nervous system for their proper performance. This explains how the various physical processes, such as menstruation, digestion—both in the stomach and intestines—the secretions, and the action of any or of all internal organs, may be affected when their centres in the nervous system

become impaired in their functions, as is so often observed in neurasthenia.

As to the class of insanity most amenable to prevention, it can fortunately be stated that one of the most frequent and important forms of this disease belong to this category—viz., that functional form which occurs in adult life, among persons who have previously enjoyed good mental health, and have already accomplished a fair share of life's work in proportion to their age, and in whom the symptoms usually follow such causes as overwork with anxiety, intense mental strain under adverse circumstances, or some pronounced nervous shock. That this form of insanity can be prevented in 75 per cent. of all the cases, when treatment is commenced sufficiently early, has already been clearly demonstrated by a practical experience of many years which were devoted to this purpose.

Before discussing the various symptoms it should be clearly understood that the symptoms of which a patient complains in neurasthenia are always as real to him as those of any ordinary physical disease. Because we often cannot see or locate any visible cause externally for the symptoms, we have become prone to doubt their existence. The prevalent conceptions of any pronounced illness have for so long been associated with pallor, weakness, emaciation, and other physical signs in the patient, that it has been a natural mistake, when judging only from the possible lack of external physical signs of disease, to consider that all the symptoms of a neurasthenic are voluntarily intensified or even imaginary. Were the truth recognised it would be seen that many of these patients struggled long to overcome their symptoms, but were unable to do so. It is this lack of knowledge, conjoined with a hasty conclusion, which is apt to lead many to think that the patient could do differently if he chose, or be quite well if he only believed it. If these persons would only consider that they themselves may one day be obliged to pass through the same ordeal as many unfortunates are doing in every quarter of the world to-day, the injustice and the unkindness of this view would be at once apparent to them—no one is immune. Moreover, in the discussion of the symptoms which follow, it is assumed that the patient has previously enjoyed good mental health, and the grouping of the symptoms here given, whilst purely arbitrary, is intended to indicate how their symptoms, when untreated, may become gradually intensified from a comparatively simple nervous affection in the early stages to a most pronounced disturbance of the functions of the brain—a fully developed insanity.

The symptoms, of which only a limited number may be mentioned here, comprise—especially in the early stages—complaints of disturbances of the various physical processes, such as are mentioned above, of which functional disturbances of the generative system in women and the digestive system in man, are the most frequent offenders. These symptoms may be accompanied in their onset by noticeably nervous symptoms, which later, unfortunately, in the past have been too often regarded as "reflex" in their origin from the physical disturbances, instead of being recognised as definite evidence of the general nervous condition. As the disease advances, the nervous symptoms gradually become more evident: sleeplessness develops, and this is often attended by disturbing or horrible dreams, the patient awakens tired and unrefreshed in the morning, even after a fair night's sleep. Undue irritability is often present, with a decided tendency to worry over trifles, loss of confidence, and marked indecision—the simplest questions being solved only after much difficulty and hesitation; an inability to concentrate the mind for any

length of time without an undue effort, which is followed by intense fatigue; reading an ordinary article, as in a newspaper, may be difficult, and the patient cannot remember or enjoy what he reads, the emotional equilibrium is easily upset, so that a strong man will shed tears without any apparent adequate cause; the lack of confidence in himself may extend to his surroundings, so that his sense of security is lacking, and fears of various kinds arise, such as the fear of being alone, or in the dark, or in open places, etc., these fears being as real to the patient, on account of his condition, as though some immediate danger were actually present; any mental effort may be commenced in good form, but rapid exhaustion follows; a lack of interest gradually develops in the usual affairs of life, and he becomes increasingly introspective; depression may now appear, at first slight and only occasionally, being easily shaken off, but later it returns with greater force, and the patient is only able to rid himself of it by a stronger voluntary effort; the courage, brightness, energy and optimism, which had characterised the individual previously, are now steadily diminishing, and he gradually begins to feel doubtful about his recovery; the ordinary affairs of life no longer interest him as they did formerly; his intellect is as clear as ever, but he is unable to sustain any prolonged intellectual effort; the daily work, which hitherto had been done cheerfully, now becomes an ever-increasing drudge, and finally is no longer possible. The patient realises all these changes, and does his best to rid himself of them, especially with the help of friendly advice, but he can only do so temporarily, as they constantly return with increased force.

It must be here noted that the above symptoms have all increased gradually in their intensity, and may have occupied months of time from their onset to this stage of the disease.

All these symptoms, which are termed psychical, indicate a diminished resistance and a disturbance of function of the higher centres of the brain, and are just as characteristic of a disturbance of the cells in these centres as a yellowish discoloration of the skin is of a certain disturbance of the cells of the liver. Efficient treatment at this stage of the disease would result in the recovery of 80 per cent. of the patients.

If we now suppose the disease has not been efficiently treated, and that in its onward progress all the symptoms have steadily become intensified, what will be the next stage? The sleep has become less and less, until the patient often believes he gets little or none; the inability to concentrate the mind has increased to such an extent that the simplest duties are performed only with difficulty; the depression has become more marked and constant, so that while the patient may be induced to smile from time to time, the hearty laugh of former times is no longer heard; he is more discouraged about his prospect of recovery, and, owing to his inability to work, he fears his usefulness in life has passed, and that he will become a burden to his friends. At this time thoughts of self-destruction flash across his mind, but are promptly dismissed from ethical or moral reasons. While discouraged about his recovery, he still clings to the hope of getting better, and desires to do so. At this stage his disease has become much more serious, and the outlook for the prevention of an attack of insanity much less bright than before. It may safely be predicted, however, that treatment will still save 50 per cent. of these patients.

If we pursue the onward course of the disease still further into another stage we find that the inability to concentrate the mind has led to a state of habitual distraction; the discouragement has become more intense and the futility of trying to

prolong his existence is ever present with him; at this time thoughts of suicide as the best means of escape from his trouble are constantly with him, and he is unable to rid himself of them; they steadily assume a more definite form and either a deliberate attempt to take his own life is made, or on a sudden impulse he ends the scene. Should this not occur, or have been unsuccessful, the symptoms grow steadily more marked; he finds that all interest in his family has disappeared, his entire thoughts being centred on his own misfortune, which is steadily becoming greater; the fears he had earlier in regard to external objects gradually extend to imaginary evils, and he is terrified by them; he asks himself why this great misfortune has come upon him, and tells himself it must be for some great evil which he has done which has caused God, and all his friends, to desert him; or he may hear a voice in the stillness of the night telling him of dreadful things about to happen to himself, such as being burned in a fiery furnace, or suffering some horrible torture, etc., the reality of which to the patient is often very evident from his actions.

During this stage the patient has passed over the boundary line of insanity, and even the friends can no longer conceal the truth from themselves, and they awaken to the dreadful reality that his disease has so far progressed that treatment in a hospital for the insane is often the only alternative which remains.

As the above symptoms are different from those of ordinary physical disease, so must the treatment be different, if it is to be successful. The first essential is to remove the patient from the surroundings in which his trouble developed, and to place him under the charge of a physician in whom he is entitled to have confidence. If the patient remains in his own home, or his usual surroundings, the pernicious influences which induce his disease still remain to produce further irritation and thus counteract the benefit of his treatment. Moreover, in a patient's own home, where he or she has been accustomed to direct, it is doubly difficult to give up everything to follow the prescribed course of treatment. Again, the visits of friends in the home, be such either social or business friends, disturb the necessary mental quietude of the patient, and these friends may often suggest, in all kindness, other remedies or other plans of treatment which, from their disturbing effect on the patient, are often most harmful to his progress. Again, a home is not provided with the facilities required for successful treatment, and these can only be had in a hospital devoted to the purpose. A most frequent mistake is made by taking half-measures, which are nearly always failures, and a more severe stage of the disease has to be contended with, owing to the time which has been wasted and the further discouragement to the patient which has ensued. It is much better in this, as in other affairs of everyday life, to make a business of it and succeed. It is often suggested that as the patient is only nervous a little rest and change is all that is required. While much depends, of course, on the symptoms at the time, it is always well to remember how the disease may progress, and be governed accordingly.

The nursing of these patients is most important, and requires a long experience with these conditions to be really efficient. The problem of being nursed by a near relative is often present, but of this it may be said that however serviceable such might be in a patient suffering from an ordinary physical illness, the result here is usually unsuccessful, owing to the special type of disease; and the nurse often breaks herself down without having in any way improved the patient's condition.

Hence, removal from home is usually imperative if the disease is at all severe, and once this has been done, it is better to keep the patient out of touch with it (except to know that the family are well) until he has made some decided progress on his way to recovery.

Once the patients find themselves in surroundings in which they have confidence, where every detail of their treatment is carefully planned for them without any effort to decide for themselves, and where the knowledge of such conditions on the part of the attending physician assures every confidence in him, they will at once experience relief from their symptoms, and will be only too willing to carry out all treatment, feeling assured that they will soon return home fully restored to health.

[At the meeting of the Ontario Medical Association, held in Peterborough, May 25th-28th, 1915, the following resolution was moved by Dr. Meyers and seconded by Dr. Hamilton: "That this Association desires to place itself on record in favour of active steps being taken immediately for the prevention of insanity by the establishment of separate Neurological Wards in general hospitals, especially in those hospitals in which clinical teaching is given." Carried.]

THE VALUE OF SYMPTOMATIC DRUG TREATMENT.*

BY JOSEPH L. MILLER, M.D.,
Chicago.

As compared with a few decades ago, drug therapy occupies a less prominent place in the treatment of disease, and inasmuch as most of our medication is symptomatic in character, it probably means that symptoms are less frequently treated than in former years. Is this to be considered a step in advance, or are we, on account of our interest in scientific medicine, negligent of an important detail in treatment? It is probably true that with the development of specific drug therapy and biological products the physician has become more impatient with and less interested in treatment directed towards giving only temporary relief. Other important reasons, however, must be considered. The profession each year contains more and more men with careful scientific training. This training may have led them to scrutinise more closely all methods of treatment through carefully controlled observations. The advance of pathological physiology, pharmacology, and experimental therapeutics has furnished them with certain knowledge, and especially a new method of applying it. As a result of all this there has developed, as it appears to the writer, a certain healthy scepticism in regard to drug therapeutics.

Certain points should be considered before undertaking any symptomatic treatment. A few that might be mentioned are: Should this particular symptom be corrected? Does it interfere or assist in bringing about improvement or recovery? Will its modification interfere with making a correct diagnosis or obscure observation upon the progress of the condition? Having determined that a certain symptom should be treated, it is necessary to determine, if possible, the underlying pathological physiology and then the agent to correct it, not merely the chemical agent but the necessary dosage and frequency with which it should be repeated in order to bring about the desired effect. To attempt to lower blood-pressure, at least under certain conditions, may be poor therapeutics; as, for instance, when due to increased intracranial pressure, when the rise in blood-pressure is an

effort to avoid cerebral anæmia. It is not improbable that hypertension of renal origin is an effort to increase the efficiency of a pathological kidney. Drug antipyretics, on account of their depressing action, have been largely abandoned in the treatment of prolonged fever. The recent investigation of Rolly and Meltzer and Ludke and others raises the question whether any method of artificially lowering temperature is desirable, as according to their experiments at least a certain degree of fever favours the development of immune bodies. Before undertaking symptomatic treatment it is wise to consider the compensatory resources of the body and not confuse compensatory action with what is commonly regarded as a disease symptom.

In the severe acute infection, if we decide that the centres in the medulla are not functioning properly, can we modify them by certain drugs? We are taught by the pharmacologists that strychnine quickens and deepens the respirations and stimulates the vasomotor centre, causing slowing of the pulse and a rise in blood-pressure. Now, if these same results were produced at the bedside upon these centres, rendered abnormal by toxins, we would have in strychnine a valuable symptomatic remedy. Whether under the conditions mentioned, and in the usual doses, strychnine stimulates these centres sufficiently to bring about any appreciable improvement is exceedingly doubtful, as shown by the observations of Cabot, Newburgh, and others. We must therefore conclude that either our conception of the pathological physiology is incorrect, and the recent work of Newburgh indicates that in this particular illustration this may be the case, or our pharmacology is at fault. Symptomatic treatment, however, when applied to the correction of undesirable symptoms by agents that have been demonstrated to correct this disturbance is strictly scientific, and in this respect is placed at once on the same level as specific therapy.

There is another group of conditions in which symptomatic treatment is not only strictly indicated but in which the agents are at hand to give relief. Morphine, when administered to a pneumonia patient with acute pleurisy, not only relieves the pain, but deepens the respiration, improves the oxygenation of the blood, promotes sleep, and thus becomes far-reaching in its results. In an acute attack of pulmonary œdema, morphine is often of considerable value, in a measure due to its relieving the patient's fears and thus lowering the arterial blood-pressure and so permitting of a restoration of function of the left ventricle. Morphine in acute biliary or renal colic relieves pain, and at the same time relaxes muscular spasm, thus allowing the calculus to escape. Adrenalin, by relieving bronchial spasm, may abort an attack of bronchial asthma. Angina pectoris, when due to spasm of the coronary artery, may be relieved by the nitrites.

There is another group of conditions in which symptomatic treatment may give only transitory relief, but when combined with other agents may give prolonged relief. This form of symptomatic treatment can only be considered scientific when associated with these additional measures; as, for example, digitalis, although claimed as a functional remedy, is nevertheless given to relieve symptoms, as, for instance, dyspnoea. Alkalies are of value in relieving gastric hyperacidity. The digitalis, however, should be combined with restriction of physical exertion and the alkalies with the proper dietary measures in order to give lasting results.

Outside of the symptoms that can be placed in these groups mentioned, or others of the same rational character, there is another group the treat-

* *American Journal of the Medical Sciences*, December, 1915.

ment of which at least to-day cannot be considered as proved rational therapy. Here might be included the value of salicylates in acute arthritis, of expectorants, of bitter tonics, of arsenic in anæmia, and of drugs used to control hæmorrhage. It is in this field that the clinical therapist can render real service. Here a process of elimination is necessary in order to place therapeutics upon the same high plane as the other branches of medicine.

In addition there is a long list of drugs employed symptomatically proven to be without value, mentioned or recommended still in modern high-class text-books. As an example we might name hexamethylenamin, which rapidly acquired a reputation as having bactericidal properties throughout the body, and when administered by mouth to appear in the form of formalin in the various excretions and secretions of the body. It is still extensively used in respiratory and ear infections, in meningitis, arthritis, and cholecystitis; although it has been clearly demonstrated that the hexamethylenamin is only split up and formalin set free in an acid medium, and of the various secretions the urine is the only one which is acid.

In order to determine the value of symptomatic treatment it is very essential that the observer be familiar with the course of untreated disease. Individual variations must always be taken into consideration. Many patients with pernicious anæmia grow progressively worse, others have prolonged periods of spontaneous improvement, the latter offering a dangerous pitfall for the unwary therapist. Perhaps in the teaching of clinical therapeutics it would be wise to instruct the student first in the course of untreated disease; if possible to follow a few cases in the ward, tabulating symptoms, their intensity and duration. He would thus be impressed with the importance of carefully recording symptoms. He would thus be in a better position to determine the effect of therapeutic agents, and so avoid the error of acquiring experience in clinical therapeutics in a haphazard and time-consuming manner. For the purpose of arriving at accurate information too much stress cannot be laid upon the statistical method of which Dr. Osler has always been a strong advocate. While the impression of our therapeutic accomplishments may be more pleasant to consider, it is carefully collected and recorded information that is of lasting benefit to medicine. Our therapeutics can be placed upon the same accurate basis as pathology and symptomatology. Symptomatic treatment is most important not only from the stand-point of the patients, but also for the purpose of clearing up the field of clinical therapeutics, and he who undertakes a careful study of symptomatic therapeutics will be rendering a lasting service to medicine.

THE CENTENARY OF THE BIRTH OF DR. CRAWFORD WILLIAMSON LONG, THE DISCOVERER OF ETHER ANÆSTHESIA.

By GEORGE FOY, M.D., F.R.C.S.I.

THE Commonwealth of Georgia has recently celebrated the centenary of the birth of Dr. Crawford Williamson Long, the discoverer of ether anæsthesia. Georgia, however, did not wait until to-day to honour the memory of Dr. Long: twenty years ago the Commonwealth named Alexander H. Stephens, the Vice-President of the Confederate States, and Dr. C. W. Long as the two citizens of the Commonwealth she deemed most worthy of statues in the Hall of Worthies at Washington. The two men were warm personal friends, and

both held appointments under the Confederacy. The Legislature of Georgia claimed the honour for Dr. C. W. Long, as one who had removed the primaæval curse from womanhood and freed surgery of the stigma of cruelty. One of Marion Sims' first pilgrimages was to Long's grave, and one of his bitterest regrets was that he had not known the man who had robbed childbirth of its terrors and surgery of pain. Writing of which, M. le Dr. Cabanès, in his classic monograph "Les Premiers Ages de l'Anesthésie," remarks "C'était trop de gloire pour un seul homme." From the earliest dawn of history we can trace the untiring search for a something to rob injuries of pain. Man has been interrogating Nature to force her to reveal the anæsthetic which would destroy pain and blunt consciousness. All people felt the want and sought for a remedy. Dangerous and even violent means to attain the desired end were sometimes adopted. The Assyrians compressed the jugular veins forcibly against the spine and thus produced loss of consciousness and loss of sensibility—a method, if not identical with garotting, very similar to that one-time method of robbery with violence. A less violent, though equally dangerous, process was the inhalation of the Mephitic vapour introduced into Egypt prior to the days of the Shepherd Kings of the Valley of the Nile. The somniferous vapour of Theoderic, inhaled from a warm, moist sponge, was in its many different formulæ a favourite anæsthetic from the days of the Greek physicians to the end of the fifteenth century, and from it Shakespeare probably took the hint for his friar's potion, which was the undoing of Juliet. The anæsthetic effects of mandragora were, experimentally and probably for the last time, utilised by the late Dr. Richardson, of London. When assisting Dr. Beddoes in his laboratory at Birmingham, William Higgins foretold that a safe anæsthetic would be found in the alkyls of the ethyl series. The writings of both Bryan and William Higgins are pregnant with thought. William was one of a brilliant company of chemists, which included Priestley, Lavoisier, Cavendish, Berthollet, Dalton, Dumas and others, and we may safely say that had William Higgins not discovered and demonstrated the principle of valency, Priestley's discoveries would have been sterile and his contemporaries unknown.

It is interesting to note the gradual approach to success of scientific investigators, and to note their tendency, like Bunyan's pilgrim, to leave the narrow path for the pleasant by-paths, where all their labour becomes nought. Beddoes and Watt and Priestley, and we may add Richard Edgeworth, strove energetically to harness Priestley's brilliant discovery as a therapeutic remedy for almost all diseases. Simple and compound gases were produced, thanks to Higgins' meticulous care, in a state of purity, and freely tested in Birmingham and afterwards in the famous Hotwells Hospital at Clifton, Bristol. The scheme ended in disaster, and the reputation of the Hotwells establishment survives on the casual inhalation of some nitrous oxide gas by Mrs. Beddoes, née Edgeworth, of Edgeworthstown, Co. Longford. At her suggestion, Humphry Davy, formerly an apprentice to Mr. Borlax, surgeon, of Penzance, inhaled the gas to relieve the toothache, and modern anæsthesia was born. As might be expected, many Bristol ladies found their way to Hotwells and visited the laboratory of the scientist and philanthropist, and, like all daughters of Eve, were a bit curious. To one and all Mrs. Beddoes and her husband were so kindly disposed, and gas inhalation formed the principal item in their entertainment. "The young man," as Mr. Watts describes Mr. Humphry Davy, administered the gas, and, as a rule, selected N₂O (nitrous oxide).

Though few knew it, and he himself discredited the idea, Dr. Beddoes was seriously ill, nigh unto death, and was working under conditions which would be considered incredible were they not verified by his autopsy. Hotwells was closed; but the amusement, for so it came to be considered—of inhaling nitrous gas survived and extended to the cities of the U.S.A. Medical students of the Edinburgh school made the practice popular there. Gradually, here and there, some stories of deaths occurring from the gas inhalation got about. Professor Mitchell's "Chemistry," published during the fright period, announced that nitrous gas was poisonous. This and the fact that the apparatus for producing the gas was expensive, caused a search for a non-poisonous and less expensive inhalant. Cullen was then the dominating therapist and clinician, and he recommended inhalation of ether as a stimulant and to relieve pain. The recommendation was approved of by Pereira and by Rush and other leaders of opinion in America. The inhalant required no apparatus and its cost was not prohibitory. C. W. Long, a student of medicine at the Jefferson College of the University of Pennsylvania—the University favoured by Southerners—saw the "ether freaks," and recognised that they were free from the toxic properties Mitchell ascribed to nitrous oxide (toxic action due to the impurity of nitric oxide gas, which had not been removed), and had both inhaled the ether vapour and administered it. When qualified and settled in Jeffersonville, Georgia, the young people of the district solicited him to administer nitrous oxide gas to them. This he could not do, as he had no apparatus, and there was no mechanic capable of making one within a hundred miles of him—an immense distance at a time when railways were not and Georgian roads hardly more than bridle-paths. Being, however, willing to oblige his friends, he suggested ether. His suggestion was adopted, and all the whites from the surrounding plantations came to the Jefferson surgery, and "inhalation parties" became as popular as "corn cake dances." Dr. C. W. Long was not unobservant. Indeed, he had to be observant, for his visitors were the children of the neighbouring planters, and in the thirties the attendance on a plantation was to the Southern physician much the same as a good dispensary is to an Irish doctor. Fortunately for us, Dr. C. W. Long tells his own story in a letter to his friend Dr. L. A. Dugar, of Augusta, Georgia. "S. Ether was used by inhalation for its exhilarating effects in Jefferson . . . in 1840 and 1841. . . . I observed the fact that myself and others, while etherised, were insensible to pain—from not suffering pain from falls and injuries which would have produced pain in persons not etherised. . . . I made inquiry of every person who inhaled ether in my presence and received injuries in regard to their insusceptibility to pain while etherised." At this time Dr. Long was visited by Mr. James Venables, a middle-aged gentleman, living in the vicinity of Jeffersonville. He selected Dr. C. W. Long, the grandson of a veteran of the War of Independence. Mr. James Venables was anxious to have a tumour of long standing, of an unpleasant tendency to become large, removed, but he dreaded the knife, which up to this was immovably linked to pain. From Dr. C. W. Long he heard that etherised persons felt no pain from wounds and that etherisation had not occasioned any death. Without further delay, Mr. James Venables consented, and on March 30th, 1842, Dr. C. W. Long successfully removed the tumour from Mr. James Venables' neck. The operation that revolutionised surgery and banished pain from labour-beds and operating theatres was performed in a small surgery in a

hamlet in the Commonwealth of Georgia. What suffering that induction of Dr. C. W. Long prevented; what lives it saved; what a factor it became in medical progress, is beyond the wit of man to say. Long saw its beneficent effects in the four years' Inter-States war, and we see it to-day in the Great War; and millions who never have heard of C. W. Long bless the means which preserves their kith and kin from the agony of pre-anæsthetic operation. Dr. C. W. Long was now suffering from the dread of having unconsciously hypnotised his patient, and that by suggestion the operation had been robbed of its pain. Peripatetic professors of hypnotism were going through the States south of the Potomac, and were certainly exercising an influence over silly individuals of both sexes, both African and American. His contemporaries strongly advised him to discontinue ether inhalations. He, however, felt that ether, when inhaled, produced anæsthesia, and he determined to give the drug a further trial. Six consecutive operations were performed under ether, and no untoward result, although in each case he gave the anæsthetic and performed the operation. He felt that the time had come to announce the glad tidings for which humanity had waited and longed for many centuries when the, to him, startling news came that on October 11th, 1846, at the Massachusetts General Hospital, Boston, Dr. J. C. Warren, in the presence of Drs. Mr. J. Biglow, A. A. Gould, Samuel Parkman, S. D. Townsend, and George Hayward, had performed an operation on a patient under "letheon" administered by Dr. W. T. G. Morton. On the strength of this case Morton and his confrères claimed that the blessing of anæsthesia came through him, Dr. W. T. Morton. Of all those present not one knew of C. W. Long's existence, or of his operations on etherised patients. Of the operation itself I transcribe the official report issued by the hospital:—

"Gilbert Abbott, age 20, painter, single. Operation by Dr. Warren. The patient having been placed in the operating chair in the amphitheatre, an incision, two and a half inches in length, was made over the centre of external tumour, just beneath the edge of the jaw, extending through skin and subcutaneous tissue. A layer of fascia was dissected off and disclosed a congeries of large veins and small arteries. Hæmorrhage was slight, no vessel requiring ligation. A curved needle, armed with a ligature, size No. 6, was passed under the mass, and the tumour included, under a knot with considerable compression. The wound was then filled with a small compress and lint, and the patient returned to bed.

"Patient continued to do well, December 7th; cicatrix perfect; tumour same size as on entrance."

Can it be said that this operation, on which Morton built his reputation, is anything other than a very minor one? No bleeding—prior to the days of the clip forceps; a skin and fascia incision and the pedicle tied. Eight weeks after the patient discharged; tumour same size as on admission. And this operation was performed four years and eight weeks after Dr. C. W. Long's, who had to cut through the dense, tough skin of the back of the neck.

During the war, Dr. C. W. Long was placed by the C.S.A. Government in charge of the Athens Military Prison Hospital, where prisoners from the U.S.A. army were interned, and it speaks volumes for Dr. C. W. Long's kindly nature and skill to know that on the cessation of the war the U.S.A. Government asked him to retain his appointment, and thanked him officially for the care, kindness, and skill he had bestowed on their wounded. Dr. C. W. Long is, probably, honoured in the way which would have been most gratifying to him: a

medallion portrait is attached to the front of the Jefferson Medical School, a handsome stone monument is placed opposite the site of his surgery, in which he operated on Mr. James Venables; in Athens, Georgia, a splendid statue marks the place where he lived; and in the Hall of Worthies of the U.S.A. his statue is allotted a place beside that of his life-long and intimate friend Alexander Stephens. As an Irishman I feel proud of his descent. The history of modern anæsthesia is a curious record of strange coincidences. Mrs. Beddoes' toothache makes known the analgesic powers of nitrous oxide; the careless manufacture of nitrous oxide introduces ether; the want of roads and the absence of mechanics in Georgia compels Long to use ether; but without his accurate observations and his sound deductions from them the world might have waited much longer for the inestimable blessing of anæsthesia.

SPECIAL REPORTS.

THE INSURANCE ACT IN BEING.—III. PANEL PRACTICE.

By DELTA.

Let not the country mock their useless toil,
Their homely ploys, their salary secure;
Nor doctors hear with disdainful smile,
Their forced and simple panels for the poor.
—*The Moxford Book of English Verse.*

A CELEBRATED critic once laid down that all parody has in its nature the essence of original sin, but medical men will feel that in Mr. Stodart-Walker's delightful lines on the House of Commons the glamour of transgression appeals seductively, although the "panels" are not altogether for the "poor." . . . Some doctors may greet them with the disdainful smile, some with a deeper emotion, and most with, by this time, philosophic acquiescence. Among the last group are many whose acquiescence is based upon entire satisfaction. The man who has been receiving threepenny fees—there are such—is glad enough to exchange such remuneration for the fixed capitation fees of the Act, and so is his more largely represented brother who has only been paid at club rates which could not possibly reward even the time, apart from the question of skill, spent on his patients. To such the Act has meant the difference between a continual struggle and, if not wealth, at any rate a competency. It is a matter of regret that these practitioners in some cases have actually continued to run private sick clubs, at the old starvation rates, for the dependents of their panel patients, a suicidal policy in view of the possible inclusion of this class of patient within the scope of the Act. It will be hard indeed then to convince the Commissioners or the public that the men who have persisted in underrating their work should not be taken at their own valuation. This contingency would matter little did it not threaten to involve the more honourable majority in a similar underpayment.

It is difficult to say how the average practitioner, with his middle-class and well-paid artisan clientèle of private patients, and a practice eked out by a sprinkling of clubs in the pre-Insurance days, has fared. The transfer of many private patients into the Panel ranks has been generally a source of loss, set off by the fact that many people whose payments were uncertain are now paid for by the Panel fees. From such enquiries as I have been able to make and a study of the press literature of the subject, it would appear that little difference on the whole has resulted, the difference being not infrequently on the debit side. It must be remembered that for a proper comparison of the ante- and

post-Insurance conditions, a long series of years must be taken, and only three years of Insurance practice have yet elapsed. Moreover, and above all, the increase in the number of contract patients inevitably means more work done in proportion to payments, for it is a universal experience that any sum of fees from contract and private patients respectively represents far more attendance on the contract patients, who are more numerous, and ask and get more done for them in proportion to the remuneration received. In other words, the Panel doctor may be making more fees, but the extra work demanded is out of proportion to those fees—a little more money, a lot more work. And to this must be added the great increase in clerical work, records, certificates, tuberculosis returns and correspondence, cards to be completed and forwarded on accepting a patient; while the best of men can hardly hope to escape for ever the correspondence and trouble connected with a complaint, however unfounded. In one class of practice, however, the doctor has lost considerably by the Act. Many men formerly reckoned among their patients the servants of a mansion or country seat, several such establishments being included in their practice. For their attendance on these employees the master of the house willingly paid such a fee as might be considered due to a member of a liberally educated profession, the fee varying from 7s. 6d. to half-a-guinea. Now these cases are merged in the Act, and with them a certain amount of the position, prestige, and independence of the practitioner.

As for those doctors who were unable to persuade themselves that their B.M.A. Pledge, given under certain circumstances, might not be revoked when those circumstances had been greatly modified or reversed, they have paid the price of honour. Whatever may be said of their conception of honour's demands, there is no one who will not sincerely respect their adherence to that conception and regret the losses it has enforced upon them. Apart from losing so many Panel patients, it is evident that 14,000,000 patients cannot be redistributed without loss falling on someone.

In contrast with his town brother, the country doctor certainly loses. Owing to the more trying conditions of practice and the generally heavy mileage, it is doubtful if any country practitioner can take over 800 on his Panel list, but this number would be thought little of by many a town doctor. Cases are reported in London where as many as 3,000 have been allotted to one man's list, and 1,000 to 1,500 are common. It is surely an injustice that patients should be paid for at the same rate in both instances, and it may be added that it is a matter of grave doubt whether more than 800 should come on any single list, if adequate attendance is to be obtained. It is without point to urge that the country man gains by being allowed to do his own dispensing. Whatever gain accrues from this is altogether incommensurate. The payment for 800 patients at 9s. is £360, for 1,500 at 7s. it amounts to £525; and it must be remembered that the average country panel is considerably below even this figure of 800, taking in both cases single men and excluding partners. Moreover, the country practice will be the more expensive to work.

Whether for better or for worse, the Act has standardised what has hitherto been known as club practice. This can only be justifiable if that kind of practice has been raised in aim and quality: has it been so raised? That it should be, was undoubtedly the desire of the promoters of the Act. The doctor was to have his attention un-

distracted from his patient by dispensing or by book-keeping—indeed, much was made of this latter point. Can the average doctor, then, give more of his time to his patient under the Panel system? I fear that the answer, as Cabinet ministers say, is in the negative. His distractions are considerably increased in comparison with the old club days. Certificates in plenty, cards to fill in and look up for each patient, as well as to sort and file from time to time, letters to write to sundry officials and others whose appetite for information grows by what it feeds upon, long and prolix circulars to peruse and remember (if possible), Panel Committees and the like to serve upon—all these things do not make for quiet concentration; especially when added to the book-keeping and clerical work connected with his private patients. The consequence, it is much to be feared, is that when the end of the day brings a brief respite from multifarious worries and duties, it is not his professional journal or text-book that the wearied man betakes himself to, but a novel: and who may cast the first stone? Remember that he is the only administering official under the Act for whom no secretary, clerk, typewriter, or book-keeper is provided. Throughout his working hours he has stiven to ward off from his charges the grim wolf with privy paw, the struggles alternating with wrestles with the goosequill. Nay, did he not, borne down by the heavy effort to bear his warring brother's burden, petition that "for the duration of the war" records at least should be more honoured in the breach than the observance? Only to be informed, by the cold scratch of Officialdom's pen, that the records could not be dispensed with. Such records including, of course, his military brother's records.

Yet, were all this pen-scratching reduced, one dares not suggest abrogated, what might it not mean to the Panel doctor? At present, I would appeal to such: What is their first thought as their Insurance patients enter their consulting-room? Is it: "Here is a Sufferer to be treated?" Rather is it not, as the doctor's hand goes automatically to the card-index drawer: "Here is another Item to be filed?" My brethren, these things ought not so to be.

Of the provision of laboratory help I may speak not unhopefully, although the grants for this and kindred services have had to be withdrawn. Sooner or later it must come. No doctor under the circumstances detailed—or rather outlined—above, can be expected to make a blood-film or stain a sputum—yet how much might be done by these aids in suitable cases! But time and in many cases even space are wanting; how much more so for the more recondite Widal test and others of its kind. In these matters a lesson ought to be learnt from the R.A.M.C., which calls in the aid of the bacteriologist promptly and reaps its reward accordingly—has not the bacteriologist won some of his most brilliant triumphs in that excellent Corps?

Closely allied to the bacteriologist's help is that which ought to be received, but which at present is not, from consultants, inspectors, referees—call them what you will—appointed under the Act, and not medical representatives of insurance corporations (such latter having, as a rule, no particular standing in the profession). These should deal with the increasing class of the work-shy, the schemer who, being out of work at the time, takes the opportunity to get up some ailment fancied or otherwise to tide him through exigencies, the downright malingerer—all of whom are a problem which the panel doctor ought not to be expected to tackle single-handed, nor to risk those medico-legal com-

plications which will threaten him to exactly the extent proportionate to his faithfulness in discharging his duty. The only "complaint" which the writer ever had to meet—certainly it was dismissed as frivolous, but not until a good deal of time, stationery, and postage, not to mention worry, had been expended—was in connection with signing a certificate for one of these gentry; and doubtless his experience can be paralleled by many others. It is not right that a doctor should be exposed to these risks.

Reverting for a moment to the vexed question of clerical work, there is at least one kind of record, for which space is provided on the back of his record cards, which the panel doctor makes, or ought to make, with a good grace: I mean the clinical notes on involved or interesting cases. At present these notes are lost to him at the end of the working year when the halves of the cards are sent away for tabulation. It is not much to ask that these clinical records should be subsequently returned to their writer after the cards have been dealt with, for the jottings are valuable as clinical references in future consultations. The trouble involved in their return need not be great, and the gain to efficiency is unquestionable.

This article has reviewed, however inadequately, the prospects of the average panel practice, both professionally and financially. But to every practice comes a time when, by removal or decease of the incumbent, a change of proprietorship occurs. How does the practice stand then under Insurance conditions? The writer's answer to this far-reaching question would be worth little, and he has therefore had recourse to the opinion of experts, who have been good enough to give him a reassuring opinion. They point out that the panel has had a good influence upon the sale of practices, because it is a certainty the value of which can be ascertained simply by reference to the local Insurance Committee. Whereas in the old days, in the case of the sale of a cash practice there was little to rely on in the investigation of the books; now the panel foundation constitutes a fixed basis from which to estimate the worth of the practice. These experts state that the average loss of panel members to the incomer is not a serious item in the transfer. Such considerations do not, of course, apply to the transfer of practices in the transition days, for during the inception of the Act's working a practice was bought and sold under a cloud of uncertainty as to the future.

Something must be said before closing concerning the claim that the average earnings of *locums* have been increased by the Act. Excluding the present abnormal war conditions, under which many patriotic *locums* have done their best to bleed dry their brethren, who have gone forth that the *locums* might pursue these venesections in peace and quietness, it is true that *locums* have received larger fees since the Act came in; but it is not always considered that they have raised their terms, being quick to perceive that the passing of the Act meant that their work would be increased. And ample proof can be adduced that it has been so increased. On the other hand, every doctor who has sought a holiday in the years immediately preceding the Act will bear witness that even then the tendency for *locums'* fees to climb up had begun. It was merely accelerated by increasing experience of the Act.

BRIGADE SURG. LIEUT.-COL. JOSEPH FLEMING, M.D., F.R.C.S., Army Medical Staff, left unsettled personal estate in the United Kingdom amounting to £20,316.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

QUACKERY AND THE ETHICS OF JOURNALISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—All your readers interested in this subject will thank your correspondents, "A Student of Sociology," and "Anti-Cant," for their letters in your issue of January 5th. "A Student of Sociology" tries to get at the root of things, and makes plain what many of us may have overlooked, namely, the fact that the vast system of swindling carried on by quacks of all denominations merely forms what is called "the last word" in the vaster system carried on by followers of the cult of "neo-commercialism." Except in so far as it ought to intervene to prevent victimisation of unbusinesslike medical men by City Sharks, the subject of commercial fraud hardly lies within the scope of medical journalism. The Shark is only one degree less hurtful than the medical quack. The one robs the simple public and often breaks the hearts of his dupes, the other not only robs, but trades upon the health and the life of those who often because they are suffering are led to confide in him. Success of financial fraud depends upon advertisement. The Prelates of our Churches of Intercession Day all spoke of the hope of that national regeneration to follow the war, of which "A Student of Sociology" treats. The hearts of at least the majority of our people are sound enough; let us hope that they will set to work when the time comes to cleanse the community from the dregs which society by its neglect has made accumulate, and that they will clear from the surface the froth and the scum which are now too often mistaken for the *crème de la crème*. The statement of "Anti-Cant" fills me with amazement, but I have verified its exactness. I see very few medical papers and never by any chance look at their advertisements. There may be a score or more of high-class medical magazines and papers published in London and the country, including several medical school journals. It is a fact that at present in the majority of these there are to be found quack advertisements which even respectable lay papers ought to reject. I will allude to two only of these advertisements. One is among the most blatant and easily recognisable frauds of the day. It consists only of a mixture of Epsom and Glauber salts disguised and made palatable. It is set forth as a "cure" for 50 or more diseases. No medical man, least of all a medical editor, can need a hint as to the injury reliance upon such trash must often inflict. The other advertisement to which I allude is that of one among many similar now appearing. It is a "tonic" which cures all forms of debility—nervous diseases, insomnia and depression of spirits in every form. I pick out this latter nostrum for remark for the reason that within the last year or so I have received from a medical friend particulars of two cases of a kind which must be now of common occurrence. There are more than a dozen of these "tonics" on the market. The Poisons Act has shut out from them the use of drugs like cocaine and morphia which they formerly often contained. They now hold no potent drugs save alcohol, but this in a dosage so large as to constitute a virulent poison. My friend's cases were one of chronic nephritis, one of diabetes—depression of spirits being the most impressive subjective symptom. After the death in each case it was found that

the patients had been taking large quantities of an alcoholic "tonic." In each case my friend communicated with a local coroner, a medical man, but after going privately into the matter the coroner decided that an inquest would be useless, essential points of evidence being obviously unavailable. This is the kind of thing which editors of some medical papers are conniving at. They are also giving sanction to the conduct of their lay brethren. The agents are now able to point out that quack advertisements which may at first be looked at askance by careful newspapers are admitted to first-class medical journals, and managers as business men cannot be expected to refuse them. Moreover, when the time for further promotion of Medical Law Reform arrives, these facts will be used with all artfulness by the defenders of quackery. They will point to the fact that quack advertisements appear in leading medical papers as proof that secret remedies are recognised by the profession as useful or even indispensable adjuncts in medical practice. It is impossible to believe that medical editors can be aware what is being done in their own advertising columns or that they have performed the plain duty of presenting to the owners and managers the Report of the Select Committee on Patent Medicines.

I am, Sir, yours truly,

HENRY SEWILL.

The Old Rosery,
Earlswood Common,
January 6th.

"WHO MADE THEE A RULER OVER US?"

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The B.M.A., I think, deserves the gratitude of the nation for voluntarily trying to organise the medical service of the Army and Navy. The Panel Committees, backed up by the Insurance Commissioners, have also done "their bit," but so far as I can see, no superior authority has appointed either as "ruler over us." I take it the General Medical Council, by its charter, has no control over what work—if any—registered practitioners choose to devote themselves to, so long as it is not "infamous" in a professional sense, and so, if doctors are so very much required, the question arises: Should not the War Office conscript doctors for war service according to their several capacities?

I am, Sir, yours truly,

JAMES HAMILTON, M.D.

Chelsea, January 8th, 1916.

DR. WM. HAMILTON, Boyle, has been appointed a magistrate for Co. Roscommon.

DR. KRAUS, of Buenos Ayres, is reported to have discovered a serum against whooping-cough.

CAPT. B. J. HACKETT, R.A.M.C., on whom the Military Cross has been conferred, was, until he joined the Army, Surgeon to the Mountjoy Prison, Dublin.

COL. GEORGE CONSTABLE GREGORY left £1,000 to King Edward's Hospital Fund, and £500 each to Middlesex Hospital and the Hospital for Women, Soho.

SIR CHARLES AUGUSTUS HARTLEY, K.C.M.G., engineer, of 26 Pall Mall, S.W., who was born at Hedworth, Durham, in 1825, and died on February 20th last, left estate valued at £59,037 gross, bequeathed £300 to the Westminster Hospital, £200 each to Charing Cross Hospital and the Victoria Hospital for Children.

OBITUARY.**DR. ALBERT WESTLAND, M.A.**

THE death took place, on December 31st, of Dr. Albert Westland, Aberdeen, at the age of 62. Dr. Westland was a very distinguished student, and graduated in medicine with honours at Aberdeen, taking the degrees of M.B., C.M. in 1875, and M.D. in 1877. He afterwards was, for many years, in partnership in London with Dr. Ford Anderson. Dr. Westland was able to retire from the practice of his profession many years ago, and since then resided in his native city. Although for many years he did not take any active part in public life, he keenly interested himself in everything pertaining to the welfare of the community. He was for a period a member of the Aberdeen Town Council, and wrought assiduously for the interests of the various departments to which he was appointed as a committee man. Dr. Westland at the time of his death was a member of the Aberdeen University Court, elected by the General Committee. In the affairs of the University he took the keenest interest. For some time he was President of the Aberdeen Liberal Association, but resigned about three years ago on account of the Government's attitude to the medical profession in connection with the Insurance Act. He has been in ill-health for a considerable time.

SIR G. S. ROBERTSON, K.C.S.I., M.P., M.R.C.S., L.S.A.

SIR GEORGE SCOTT ROBERTSON, one of the heroes of the defence of Chitral, has died at his town residence in Chelsea, at the age of 64. Sir George, who came of an Orkney family, was born in London in 1852, and was educated at Westminster Hospital Medical School, qualifying L.S.A. in 1876 and M.R.C.S. in 1877. He joined the Indian Medical Service in 1878, and served through the Afghan campaign in 1879-80. Having retired with the rank of Lieut.-Colonel in 1888, he became attached to the Indian Foreign Office, and was continually employed on the Gilgit frontier of Kashmir. Travelling in Kafirstan, he lived for a year among the wild hill-men. In 1893 he led a political mission to Chitral, and two years later was besieged in Chitral Fort by the hill tribes and severely wounded. He gave a thrilling story of the siege in his book "Chitral: The Story of a Minor Siege." The gallantry and determination of Robertson's defence, so important for the maintenance of British prestige, was universally recognised. He was created K.C.S.I., and was made British Agent in Gilgit. Sir George had been Liberal member for Central Bradford since 1906. He is survived by his second wife, a daughter of Samuel Laurence, the painter, and by a daughter.

DR. H. L. ATKINSON, B.A., M.B., B.Ch., B.A.O., ROTHERHITHE.

WE regret to announce the death, as the result of an accident, of Dr. Hugh Latimer Atkinson, of Rotherhithe. Dr. Atkinson, who was one of the most popular medical men in the district, was killed on New Year's Day in the Lower Road, Rotherhithe, where he had his surgery, in a collision between his motor-brougham and a motor-bus. His chauffeur was badly injured. Deceased received his medical training at Queen's College, Belfast, and qualified M.B., B.Ch., B.A.O., R.U.I. in 1891.

DR. T. J. WALKER, who last August received the freedom of the city of Peterborough, was on December 22nd presented with his portrait in oils. Accompanying the portrait was a book containing the names of 750 subscribers, and bearing the following inscription:—"On the completion of the eightieth year of his age, his friends and neighbours presented Dr. Thomas James Walker, Doctor of Medicine, Fellow of the Royal College of Surgeons. Justice of the Peace, Volunteer Decoration, his portrait painted by Fiddes Watt, A.R.S.A., as a token of their esteem and affection. Peterborough, December, 1915."

MEDICAL NEWS IN BRIEF.**Medical Society of London.**

THE meetings of this Society will be resumed for the present session on Monday next, January 17th, at 8.30 p.m., when a discussion on "Gunshot Wounds of the Chest" will be introduced by Colonel Sir John Rose Bradford, M.D., F.R.S., A.M.S., Captain Hubert Henry, R.A.M.C., and Captain Morriston Davies, R.A.M.C.T. Lieut.-Colonel W. Hale White, M.D., R.A.M.C.T., Dr. Samuel West and others will take part in the discussion.

The Lettsomian Lectures will be delivered on the following Monday evenings at 9 p.m., February 7th and 21st, and March 6th, by Major F. W. Mott, M.D., F.R.S., R.A.M.C.T., on "The Effects of High Explosives on the Central Nervous System."

The Royal Society of Medicine.

At a meeting of the Section of Odontology on January 24th, a paper will be read upon "The Significance of the Radiographs of the Pitted Teeth," by Mr. W. Courtney Lyne, L.D.S.

Lectures at the Royal College of Surgeons of England.

A COURSE of lectures on "The Anatomy of the Body," for first-aid and ambulance students, will be given in the theatre of the College, Lincoln's Inn Fields, by Professor Arthur Keith, Conservator of the Museum, at 5.30 p.m. on the undermentioned dates:—February 14th, 16th, 18th, 21st, 23rd and 25th, March 13th, 15th, 17th, 20th, 22nd, 24th, 27th, 29th and 31st, April 3rd, 5th, 7th, 10th, 12th, 14th, 26th and 28th, and in May on the 3rd and 5th of the month. The course is open to all members of ambulance companies and of first-aid classes. A detailed syllabus of the subjects to be dealt with in each lecture will be issued at the commencement of the course. Anatomical preparations and specimens will be on exhibition in the theatre from 4 to 7 p.m. on lecture days.

Typhoid at the Front.

MR. TENNANT, in the House of Commons on January 10th, in reply to a question by Mr. Thorne, stated that from the beginning of hostilities to November 10th last 1,365 cases of enteric fever were reported as having occurred among British troops in France and Belgium. Of these 1,150 had been diagnosed after bacteriological examination. In 579 cases where there had been inoculation there were 35 deaths, and in 571 cases where there had been no inoculation there were 115 deaths.

Medical Attention for Measles.

At the last meeting of the Burnley Health Committee the Deputy Medical Officer reported that he had received a circular from the Local Government Board as to the Compulsory Notification of Measles Order, in which was pointed out the necessity for all persons suffering from measles to be medically attended. The Committee decided that the necessary steps be taken to ensure medical attention in such cases, and that when persons so suffering could not afford a doctor a medical practitioner be allowed a fee of 5s. to attend them, such fee to include three attendances and necessary medicine.

Child Mortality at Dewsbury.

THE Dewsbury Corporation passed the following resolution at a meeting held on December 2nd:—"That having regard to the excessive early infantile mortality and the high maternity death-rate prevailing in the borough, the Health Committee be requested to take immediate action by the adoption of such administrative measures as may be calculated to effect some improvement in those directions, and to take such further steps as will ensure definite procedure for putting into operation the recommendations

of the Local Government Board in relation to maternity and child welfare."

This resolution was considered by the Health Committee at a meeting on December 7th, when the Medical Officer (Mr. T. O. Halliwell) was instructed to report to the Committee on the following matters:—

(1) The rate of infant mortality in the borough for each of the five years preceding amalgamation, and for each of the five years following amalgamation, such return to give full particulars of the number of children that died before reaching the age of one week, also each week up to four weeks, and then for each succeeding month up to one year.

(2) The rate of mortality amongst women dying from childbirth for the same periods, giving separate returns (if possible) for married and single women, and showing whether such mortality is of a systematic or incidental character.

The final recommendation of the Committee is that, "if such rate of mortality is found to be excessive when compared with towns of a similar size and character to our own borough, he (the Medical Officer) be requested to advise what further provision is necessary, in his opinion, to minimise such excessive mortality."

Health Record.

THERE was not a single death from scarlet fever in Huddersfield during the past year, which is a unique experience in the history of the borough, and believed to be a record for any town of similar size in the country.

During the year 336 cases of scarlet fever were treated at the Corporation's Sanatorium at Mill Hill. The average death-rate throughout the country for scarlet fever is 3.5 per 100 cases.

Manchester City Coroner.

THE Manchester Corporation Town Hall Committee on Wednesday decided to recommend the Council to appoint Mr. William Sellers, M.D., M.R.C.S., barrister-at-law, to the office of Coroner for the city in succession to the late Mr. A. E. Gibson. The commencing salary is £800 per annum. Originally there were 10 applicants. Mr. W. Sellers was for a time Medical Officer of Health to the Radcliffe (Lancs.) Local Board. He was called to the Bar at the Middle Temple in June, 1900, and practised on the Northern Circuit. Later he became Coroner for the Salford District of the County of Lancaster. Besides being President of the Oldham Munitions Tribunal, he is a Professor of Medical Jurisprudence at the Manchester University and a member of the Senate. He is also a member of the Royal College of Surgeons. When the late Mr. Gibson was appointed City Coroner, Mr. Sellers, in the final voting, received only one vote fewer than Mr. Gibson.

How Disease is Spread.

At the Alfreton Urban Council meeting on January 4th, the Medical Officer reported that whilst scarlet fever was so prevalent in Somercotes some people were very careless, and caused the disease to be spread. One young woman, whilst suffering from the disease, travelled in a closed cab with a soldier to the station. This was a very serious matter, as the soldier at the time was returning to camp and might have carried the disease inside. The Council decided to take action in the case.

Housing Problems.

At the first Scottish National Conference on Housing, which was held in Glasgow on January 3rd, under the auspices of the Local Labour Party Housing Committee, Mr. William Gallagher, of the Scottish Co-operative Society, the Chairman, characterised the stoppage of the house-rent increases as a great victory for working-class solidarity. He was sorry the public had not acted similarly towards increases in the price of food, clothing and coal.

Dr. Chalmers, the Glasgow Medical Officer of Health, said the quickest way to reduce the price of

land in the cities was to cut down the height of tenement houses. The time had come when the abolition of the apartment houses should be considered.

Councillor Wheatley declared that the famine in houses in Scotland could be traced in a measure to combines among the manufacturers of building materials. Private building enterprise had failed. He outlined a labour scheme for free State house-building grants.

British Gift to Canadian Red Cross.

THE Canadian Medical Service and Canadian Red Cross have received a donation of £25,000 from the British Red Cross, to be devoted to the building and equipping of recreation-rooms at Canadian hospitals and convalescent homes now established in England and on the Continent. This may be regarded as a practical acknowledgment of the generosity of the people of the Dominion towards the Red Cross service of the Mother Country.

French Canadian Hospital.

At the end of this month there will be opened at St. Cloud the French Canadian hospital, the gift of the Canadian Government for the wounded of the French Army. It is the outcome of the meeting between Sir Robert Borden and President Poincaré in August.

Hereford Asylum.

THE new Medical Superintendent of the Hereford County and City Asylum, in succession to the late Dr. Morrison, is Dr. T. C. Graves. The salary is £500 per annum, with emoluments, which are estimated at £250. Dr. Graves entered service at the asylum in April last as Assistant Medical Superintendent, and, owing to the illness of Dr. Morrison, has been in charge during the past six months, Dr. Stevenson, another assistant, having joined the R.A.M.C. Dr. Graves, owing to the difficulty in obtaining another junior, is still working single-handed.

The new Superintendent, who is 32 years of age, has held the following appointments:—House Surgeon at the University College Hospital, London; Obstetric Assistant at the University College, London; Casualty Officer at the London Temperance Hospital; Assistant Medical Officer at the Mile End Infirmary, London; Assistant Physician at the Royal Edinburgh Asylum, Morningside; and Assistant Medical Officer and Acting Medical Superintendent at the Hereford County and City Asylum.

Arrangements for Convalescent Officers in Switzerland.

We are asked by the Committee of the Public Schools Alpine Sports Club to announce that they have accepted an offer made to them by the Board of the Palace Hotel, Montana (Switzerland), to place that hotel at their disposal, rent free, for the present winter season for the reception of convalescent officers. It is intended to follow this immediately with arrangements for Great Britain. A charge of 6s. 6d. per day to cover cost of food and other expenses will be made to each officer. Friends who accompany them will pay 8s per day. Any balance remaining over after defraying the cost of food, wages, and other working expenses will be devoted by the Committee to defraying the expenses of necessitous officers.

Montana-sur-Sierre enjoys the highest record for winter sunshine of any Swiss mountain resort—7½ hours of possible sunshine on the shortest day.

All convalescent officers, especially those suffering from bronchitis, pneumonia, and general debility and overstrain, are invited to fill in the enclosed slip and send it to the Honorary Secretary of the Sub-Committee, Lady Waterlow, 1 Maresfield Gardens, Fitzjohn's Avenue, London.

Indian Students' War Service.

MR. C. E. MALLETT, in his report on the work of the Indian Students' Department for 1915, says that from August, 1914, onwards the great majority of students at British educational centres responded steadily to

the call for men. University, law, medical, and engineering students volunteered on every side for service, and Indians were as willing as any to take their part in the burdens of the war. A way was found of enabling many Indians in this country to render valuable service in connection with the war by the formation of an Indian Volunteer Ambulance Corps. In all 272 members were enrolled in that body, and 215 officers and men were at one time or another actively employed.

Hospital Saturday Fund.

At the quarterly meeting of the Board of Delegates of the Hospital Saturday Fund, held at the National Sunday League Offices, it was reported that the total receipts up to December 31st amounted to £26,454, which was an increase of £4,633 on the previous year's total. The accounts do not close until January 10th, and it is expected that the total will be increased by that date to an additional £10,000. The Lord Mayor has consented to act as President during his year of office.

Doctors and Enlistment.

PRESIDING at the Middlesex Insurance Committee on January 3rd, Mr. W. Glyn-Jones, M.P., said the panel committees were being asked how many more medical men could be spared for enlistment. Several of their doctors had enlisted, and he thought it desirable that others should be reminded that under their agreements they had to give notice to the panel committees so that the latter should be satisfied that the panel would not be rendered inefficient, and that satisfactory arrangements had been made.

Kaiser's Corfu Palace as Serbian Hospital.

It is reported from Athens that the British Government has announced to the Greek Government its intention of taking over the Achilleion, the Emperor William's Palace at Corfu, as a hospital for wounded Serbians.

Generous Russian Offer.

THE following is issued by the War Office:—
"Prince Oldenburg, head of the Russian Red Cross, has offered to place the watering places in the Caucasus and the Crimea at the disposal of the Government for the use of wounded and invalided British officers. The invitation included the grant of a free railway ticket to the officer's destination and free medical treatment. The Government regret that they have been obliged to decline this very generous offer as, under present conditions, access to these watering places is not practicable.

Ceylon and the Red Cross.

THE Secretary of State for the Colonies has been informed by the Governor of Ceylon that a further contribution of £9,325 3s. 11d. has been made to the Prince of Wales's Fund, so that the total contribution from Ceylon now amounts to £39,325 3s. 11d. Two remittances amounting to £3,017 11s. 6d. were also sent to the Red Cross Fund last November.

Heredity as a Factor in Alcoholic Degeneration.

THE Temperance Colleague Association offer two prizes, of ten and five guineas respectively, for the best essays on this subject sent in by September 30th next. It is stated that strength and clearness of argument, rather than conclusions reached, will influence the examiners; and that original and well-attested evidence will count more heavily than quotations from existing well-known sources. Conditions, with suggestive synopsis and bibliography, may be obtained from the Secretary T.C.A., "Strathblane," Alexandra Park, Nottingham. In this connection the Science and Education Committee of the National Temperance League is willing to consider applications from University and hospital students in physics and medicine for financial assistance in carrying on research or in making investigations. Address the Secretary, N.T.L., Paternoster House, London, E.C.

Royal Colleges of Physicians and Surgeons.

AT the first Professional Examination of the Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons of England, held on January 4th, 5th, 6th and 7th, the following candidates were approved in the under-mentioned subjects—viz.:—

Chemistry and Physics.—V. H. Barker, E. R. Boland, E. Brazao, H. Dryerre, H. M. Gerson, W. Hardman, E. R. Jagger, H. S. N. Menko, G. G. Newman, H. N. Schapiro, W. Walsham, and Octavia M. Wilberforce.

Chemistry.—S. Hazeldine, Madeline P. Parker, G. K. Reeves, and B. R. Reynolds.

Physics.—H. L. Bowen, J. W. Hulme, A. A. Knapman, Margaret O. Meek, and G. F. Smith.

Biology.—V. H. Barker, J. B. Barnett, E. R. Boland, H. Brookman, H. S. Chadwick, S. H. Coplans, C. W. Empey, H. M. Gerson, Kate Glyn-Jones, J. B. Gregor, Ahmed Hamid, E. Hardy, E. R. Jagger, Mohammed Abdul Razzak Khalifa, A. A. Knapman, Margaret Omler Meek, H. S. N. Menko, H. S. Morris, L.D.S.Eng., J. L. C. O'Flynn, E. A. I. Phillips, Betsy Porter, E. L. J. Reason, G. K. Reeves, I. Resnikoff, and H. N. Schapiro.

MEDICAL WAR ITEMS.

LIEUT. W. FRANK THOMPSON, Royal Army Medical Corps, has died of wounds received in action. Lieut. Thompson was educated at Leys School, Cambridge, and St. Bartholomew's Hospital, and was 28 years of age.

Officers in the Campbell Hospital, 10 Cambridge Square, Hyde Park, include Lieut.-Col. G. A. Troup, Royal Army Medical Corps, and Lieut.-Colonel H. M. Nicholls, Royal Army Medical Corps.

Captain Albert Guy Miller, R.A.M.C., attached 12th Middlesex Regiment, fell in France on December 29th, aged 31 years. A member of an old Australian family, he was the fourth son of the late Albert Miller, of Whernside, Toorak, Melbourne. After specialising in his profession in England, he offered his services, as a medical man, to the country. He was killed during the course of his duties in the trenches by a grenade discharged from a rifle. He leaves a widow.

Major Frederick Miller Johnson, A.M.C., M.D., who was killed at Anzac on November 29th, was formerly in practice in Melbourne, Australia. He received his medical education at Melbourne, Edinburgh, Vienna and Heidelberg, obtaining his M.D. at Edinburgh in 1888. Major Johnson was a grand-nephew of the late Sir William Gull, Bt.

Surgeon Douglas Whimster Keiller Moody, M.D., R.N., lost his life in the *Natal* on December 30th. Surgeon Moody, who was gazetted in September last, was educated at Montrose Academy and Aberdeen University, where he took the degree of M.D. He ultimately settled in London, and was for some time the Medical Officer on P. and O. liners. Before joining the Grand Fleet he was a Surgeon at the Haslar Naval Hospital. It was only three weeks ago that he spent his furlough in Hull. Surgeon Moody's great-grandfather, Capt. James Whimster, of the 70th Highlanders, fought in the Peninsular War in Lisbon and Coruña under General Sir John Moore. Captain Whimster also served in Wellington's campaigns.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

ROMAN (Norwich).—In the week ending January 8th, there were notified in Birmingham 463 new cases of measles.

G. N. B. (Perth).—We hope to publish a paper on the subject at an early date.

A LUCKY YAWN.

RENDERED deaf, dumb, and blind at Festubert, a corporal of the 7th King's Liverpool Regiment gradually recovered his sight and hearing but remained dumb until December 31 when, after dancing at a wedding at which he was best man, he yawned, and recovered his full speech. He then sang a song, to the pleasure of the wedding party.

BETA (Walsall).—We refer to the matter in our editorial columns.

A WILLING PATIENT.

A TOPEKA man was complaining of rheumatism. "There's no excuse for your being afflicted," said a friend. "I used to have rheumatism. When it would strike me I would go home and have my wife throw her arms around my neck and give me a massage treatment. It helped me every time. You ought to try it." "I will," said the man "When will I find your wife at home?"—*Pacific Medical Journal* for December.

ANXIOUS (Canterbury).—Authorities have not further limited the duration of treatment, even with the most modern therapeutics.

IS IT APPRECIATION?

SOUTHWARK guardians are offering £10 notes to nurses who remain in the service for a year.

ANON. (London, W.).—We reported the meeting of the society in question, and this week publish a notice of a future discussion.

SFES.—The last appointment was made in 1907, the holder being subject to re-election annually.

BART'S MEN IN THE WAR.

A SERVICE in memory of former St. Bartholomew men and students of the hospital who have fallen in the war during the past year, will be held on January 13th at one o'clock in the Hospital Church of St. Bartholomew the Less.

J. WATSON.—The suggestion appears to us to be sound. Our correspondent had best write to Sir Alfred Keogh, Director-General of the Army Medical Service at the War Office, with whom, no doubt, an interview could be arranged.

INDIAN WOUNDED AT BRIGHTON.

No more Indian wounded are to be accommodated at Brighton. About 5,000 have already been treated at the Brighton Hospital.

RAMPANT (Hexham).—No further correspondence on the subject has been received.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 12TH.

HUNTERIAN SOCIETY (1 Wimpole Street, W.).—9 p.m.: Hunterian Society Lecture.—Mr. T. H. Openshaw: Amputations, their Prevention and After-treatment.

FRIDAY, JANUARY 14TH.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith Road, W.).—8 p.m.: Special Clinical Evening.

MONDAY, JANUARY 17TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: A Discussion on "Gunshot Wounds of the Chest" will be introduced by Col. Sir J. R. Bradford, M.D., F.R.S., A.M.S., Capt. Hubert Henry, R.A.M.C., and Capt. Morrison Davies, R.A.M.C.T. Lieut.-Col. W. H. White, M.D., R.A.M.C.T., Dr. S. West, and Dr. Murray Leslie and others will take part in the discussion.

TUESDAY, JANUARY 18TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF THERAPEUTICS AND PHARMACOLOGY (1 Wimpole Street, W.).—4.30 p.m. Sir James McKenzie, F.R.S., will open a Discussion "The Soldier's Heart." Fellows desirous of taking part are requested to communicate with the Hon. Secretaries.

Vacancies.

Royal Infirmary, Sheffield.—Resident Surgical Officer. Salary £140 per annum, with board, residence, etc. Applications to Jno. W. Barnes, Secretary.

Bury Infirmary.—Senior House Surgeon. Salary £250 per annum, with board, residence, and washing. Applications to the Honorary Secretary, Infirmary, Bury, Lancs.

Bury Infirmary.—Junior House Surgeon. Salary £150 per annum, with board, residence, and washing. Applications to the Honorary Secretary, Infirmary, Bury, Lancs.

New Hospital for Women, Euston Road, N.W.—Pathologist. Salary £125 per annum. Applications to the Secretary.

North Riding Infirmary, Middlesbrough (General Hospital).—Lady Resident Surgeon. Salary £120 per annum, with board, apartments and laundry. Applications to Charles Postgate, Secretary-Superintendent.

Herefordshire General Hospital.—House Surgeon. Salary £250 per annum, with board, residence, and washing. Applications to Wm. A. W. Price, F.C.I.S., Secretary.

South Devon and East Cornwall Hospital, Plymouth.—House Physician. Salary £240 per annum, with board, residence, and washing. Applications to P. J. Langdon, Secretary.

Borough Hospital, Birkenhead.—Junior House Surgeon. Salary £180 per annum, with board and laundry. Applications to The Secretary.

Worcester County and City Asylum, Powick.—Junior Assistant Medical Officer. Salary £250 per annum. Applications to the Medical Superintendent.

Derbyshire Royal Infirmary, Derby.—House Physician and Casualty Officer. Salary £200 per annum, with board, residence, etc. Applications to E. Forster, Secretary.

Appointments.

FIELD, F. A. M.D.Lond., Deputy Medical Officer of Health of the Fallsworth Urban District Council.

GRAVES, T. C., M.B., B.S.Lond., has been appointed Medical Superintendent of the Hereford County and City Asylum.

MACKEITH, JOHN, M.B.Glasg., Medical Officer to the Tuberculosis Department of the Central London Throat, Nose, and Ear Hospital.

TAYLOR, P. C. P., L.R.C.P., L.R.C.S.Edin., L.R.F.P.S.Glasg., District Medical Officer of the Tenterden Union.

Births.

INGRAM.—On December 29th, at Puerto, Orotava, Teneriffe, the wife of Dr. J. K. D. Ingram, of a daughter.

KERR.—On January 7th, at "Ailsa," St. Helens, Lancs., the wife of James R. Kerr, Ch.M.Glasg., of a son.

PEACHELL.—On January 2nd, at Whitecroft, Carisbrooke, Isle of Wight, to Dorothy, the wife of Dr. Ernest Peachell—a son.

Marriages.

AINGER—WILLIAMS.—On January 7th, at St. James's Church, Brighton, and on December 29th, 1915, at the British Consulate, Rouen, William Bradshaw Ainger, F.R.C.S., Captain, R.A.M.C. (T.F.), late of 58 Sloane Street, and No. 2 Red Cross Hospital, Rouen, son of the late H. J. Ainger, of Christchurch, N.Z., to Elsie Mary, daughter of the late William Williams, of Courts Heart, Briton Ferry, S. Wales.

DAVIES—FOSTER.—On January 5th, at St. Michael and All Angels' Church, Northampton, Captain J. P. H. Davies, R.A.M.C. (T.), only son of the late Dr. Idris Naunton Davies and Mrs. Davies, of Ystrad Rhondda, to Marjorie Etheldred, only daughter of Leonard Burchaell Foster and Mrs. Foster, 9 East Park Parade, Northampton.

DE BOURG—DENNY.—On January 4th, at St. Columba's Church, Pont Street, Dr. Walter de Bourg to Helen Leslie Denny, only surviving child of the late William Denny, of Dumbarton, and the late Lelia Lady Samnelson.

GIBSON—HALL.—On 6th January, at the Parish Church, Holt, Norfolk, David Gibson, M.B., Ch.B., S. Sylhet, India, to Christina Collinge, youngest daughter of Mr. and Mrs. W. J. Hall, late of Heaton Mersey, Manchester.

GRIEVE—BELL.—On January 4th, at Wallasey Parish Church, Kelburne King (West African Medical Service), fifth son of the late Dr. Robert Grieve, C.M.G., Surgeon-General of British Guiana, to Ethelwynne, youngest daughter of the late Dr. Bell and Mrs. Bell, Ivy Cottage, New Brighton.

STEVENSON—MCCRAE.—On January 5th, at St. Alban's Church, Birmingham, Captain G. H. Stevenson, R.A.M.C. (S.R.), son of G. H. Stevenson, Esq., and Mrs. Stevenson, Haddington, N.B., to Grace Dorothy, youngest daughter of the late James McCrae, Esq., and Mrs. McCrae, of Mosley.

WARNER—MALLET.—On January 6th, at St. Alban's Church, West Kensington, Charles Horne Warner, B.Sc., F.I.C., D.I.C., youngest son of the late Yardley Warner, Esq., of Philadelphia, and of Mrs. Warner, to Refina Mallet, M.R.C.S., L.R.C.P., elder daughter of Mr. and Mrs. Chas. Mallet, of Fiskerton, Notts.

WILKINSON—GROOM.—On January 8th, at Stokesay Parish Church, John Douglas, Lieutenant, R.A.M.C., only son of Mr. and Mrs. John Wilkinson, of Sutton, Surrey, to Ida, youngest daughter of Mr. and Mrs. Herbert Groom, of Stokesay, Shropshire.

Deaths.

ATKINSON.—On January 1st, as the result of an accident, Hugh Latimer Atkinson, M.B., 211 Lower Road, Rotherhithe, S.E.

DAVIS.—On December 30th, Surgeon Lieut.-Colonel J. Norman Davis, of Clondarragh, Foxrock, co. Dublin, in his 78th year.

FAGGE.—On January 2nd, at 15 Effingham Road, Lee, Kent, Frederick Thomas Fagge, M.R.C.S., L.R.C.P., aged 76.

HEWITT.—On January 6th, at 146 King's Road, Brighton, Sir Frederick William Hewitt, M.V.O., Anaesthetist to his Majesty the King, late of 14 Queen Anne Street, W.

IMPEY.—On December 30th, Elizabeth Stephens Impey, M.B., Ch.B., by torpedoing in the Mediterranean of the S.S. Persia.

SCOTT—ROBERTSON.—On January 2nd, at 14 Cheyne Walk, Chelsea, Sir George Scott Robertson, K.C.S.I., M.P., aged 63.

WILLIAMS.—On January 7th, at Bournemouth, Samuel White Duckworth Williams, M.D., elder son of the late William White Williams, M.D., F.R.C.P., of Hayes Lodge, Cheltenham.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, JANUARY 19, 1916.

No. 3.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

Medical Matters and the **Lay Press.** THERE have recently been a good many very pertinent and timely letters addressed to the more influential of the dailies on subjects connected with the medical side of the war. A curious and disappointing fact about these letters is that they are all of them pseudonymous, a feature which deprives them of more than half their weight. I suppose it is not in consonance with military discipline for an officer, under his own name, to criticise the War Office in the public Press, and as an enormous number of medical men have been cajoled or whipped into the military fold, the profession, the members of it at any rate who can speak from first-hand knowledge, have thus automatically been rendered inarticulate. This is a serious, but by no means the most serious, disadvantage of the militarising of the profession which has been steadily going forward since war began.

Militarisation. It has always been a puzzle to some of us to discover any adequate reason for this militarisation. That a man is willing to place a portion of his time and brains at the disposal of his country, in the service of the sick and wounded, is no sufficient reason for putting him into uniform and labelling him with a military title. I do not refer to those who are entirely given over to military work either at home or abroad, but to those who merely because they are on the staffs of the large general hospitals in London, are made to masquerade as military. This useless procedure was bound to give rise to many anomalies, and there have been bitter complaints of the many undignified absurdities which have thus been caused. A civilian medical man is a medical man first, and the fact that he is looking after soldiers cannot make him into a military medical man. Let the shoemaker stick to his last and the civilian doctor to civilian garb. The be-uniforming, the shaving of grey beards and the other concomitants of militarisation are really very undignified.

Incongruity. I RECENTLY saw a list of names of those who were to speak on some scientific question at the Medical Society of London. Nearly all of them were well-known and honoured

names in the medical world, and most of them wore the disguise of military rank. That kind of thing is simply childish. I was once present at a function at which the degree of LLD. was conferred upon John Bright. One of the University functionaries, in speaking of the great tribune immediately after the ceremony, referred to him as "Dr." Bright. The same shock of incongruity as then overcame me finds itself repeated when I see it recorded that Surgeon-General Rolleston, or Major Sir John Bland Sutton are to record their views on the proper treatment of wounds or on the nature of trench foot. The distinction which properly attaches to the names of these and other gentlemen is purely scientific, and they should decline to allow it to be hidden beneath unsuitable trappings borrowed from a temporary sphere. Very few LLD.'s or D.C.L.'s call themselves "Dr." It is done, but not in the best circles. Imagine Dr. Tennyson, Dr. Arthur Balfour, or Dr. Asquith. D.D.'s, on the other hand, are not infrequently referred to as "Dr." Occasionally a Mus. Doc. likes to be thus addressed.

The Khaki Woman.

BUT if the uniformed, beard-bereft elderly physician is an unedifying spectacle, what is to be said of the khaki-clad woman? In extenuation of the plight of the former it is to be urged that he is only obeying orders; if anything can be advanced in excuse for the frightfulness of the latter I have not yet heard it. That civilian men should be forced, not always unwillingly be it admitted, to play at soldiers is a pity; that women should thus voluntarily mask themselves is an insult to good sense and good taste. We are constantly being reminded of the marvellous work which women are doing in the war. It is not necessary to belittle the work in order to realise that it is being uncommonly well advertised. We shall not be allowed to forget that women have undertaken a great deal of work which used to be done by men, but that does not necessarily mean that the work is being as well done as it was before, it merely means that, after a fashion, it is being done. The public and employers are properly indulgent to women in these new spheres. Because of her sex, inefficiency in these new activities is tolerated in a woman, and mediocrity is aggrandised

into genius. If the khaki-clad woman has any *raison d'être* it is merely as a part of an uncommonly well-organised advertising scheme, the full fruits of which will not be brought home to us until peace is declared. If these stupid women must ape the military, they might at any rate seek to cultivate some degree of military smartness in appearance. The *tenue* of some of them is deplorable in its combination of sloppiness and unsuitability.

Furlough.

A CORRESPONDENT of the *Times*, signing himself "X," makes the excellent suggestion that "the time is come when the remnant of the famous Expeditionary Force that went to France in August, 1914, should be withdrawn from the front for a period of three or four months." These officers and men, more especially, perhaps, the officers, are entitled to a period of relative comfort and lessened responsibility, and it would add to their efficiency if they obtained it. "X" goes on to say, "I saw them after the great retreat and the advance on the Aisne, and was delighted to observe their fine condition of mind and body. I have seen some of the same men lately home on short leave, and although they were all resolute and confident, they seemed to be many years older, war-worn and jaded." That is exactly what one would expect, especially from the monotonous conditions imposed by trench warfare. There are hundreds of very efficient officers and men who are bursting with impatience to go out; why are not the former replaced by the latter?

The Medical Future.

THE Editor of the *British Journal of Dental Science* writes a letter to the *Times* in which he says: "Those who assert that sickness among civilians can be dealt with, even if the new Armies withdraw from civil practice the majority of the younger doctors, claim that the older men and even retired practitioners can undertake their duties. As a member of the teaching staff of a London hospital for many years, I know that the medicine and surgery taught to-day are absolutely new systems when compared with those current a generation ago. If all the young educated doctors leave us not only will the civil population have too few doctors, but it will be deprived of most of those educated in modern scientific methods. The preservation of infant life is to-day of paramount importance; to ensure it we need clean midwifery and assured knowledge of pædiatrics."

THIS is sound sense. No one knows better than the medical man who has been out of harness for a year or two how quickly the tide of moving ideas and improving methods sweeps over him. Even the country practitioner, who has to be physician, surgeon, midwife, oculist, and the rest, when, after a few years he revisits his hospital, is forcibly struck with the changes, not only in *technique*, but in underlying principles which have taken place since he was a student. The public thinks that once a man is a doctor he is always a doctor. This is, of course, in one way

true; a rusty doctor in any medical post is infinitely better than the keenest layman, but it is also true that there is no profession in which rust gathers more surely than in ours, and what is wanted for the near future is not rust, but the latest knowledge and the greatest keenness, and these are what are now being withdrawn wholesale from the effective ranks of the profession.

The Dental Future.

THE writer then proceeds to state the case from the point of view which specially appeals to him and on which he is eminently qualified to be heard: "The recruiting authorities are dealing even more hardly with dentists, dental students, and dental mechanics than with medical men. All three classes, unless possessing a medical as well as a dental qualification, are told they must enter the ranks as combatants. If they are medically qualified they must join the R.A.M.C. The result is that a most serious deficiency of dentists imbued with modern methods is rapidly developing, while there are no students left at the dental schools preparing to follow on." This is, of course, as much a medical and hygienic matter as it is a dental. The time is long past when dentistry was regarded as a mere side track on the road of medical science. The dental surgeon of to-day is scarcely less important than the abdominal surgeon, but he must be of to-day and not of the day before yesterday. The mouth is now recognised as one of the most frequent and potent provokers of disease, and to be efficient its care must not only be skilful, artistic and learned, but it must, above all things, be unremitting in its vigilance. To make combatants of the men who are qualified, and were qualifying for such work is typical of the unimaginative wastefulness in human material which is now rampant. Mr. Lloyd George has been reproving himself and his colleagues for their tootleness. I hope some imagination and foresight will be brought to bear upon the medical situation before it becomes too late to remedy it.

"Advice" from the L.G.B.

IN the *Leicester Mail* it is reported that at a meeting of the Hinckley Guardians, "Dr. Murray, who is succeeding to the late Dr. Barrett's practice, applied for the position of medical officer held by the latter. As he is of military age, it was decided, on the advice of the Local Government Board, not to appoint him." I sincerely hope that some one in the House of Commons will ask a question of the President of the L.G.B. on this subject. On the available information, it would be difficult to imagine a more tyrannical exercise of influence or a more unwarrantable piece of interference than this "advice" of the Local Government Board. It probably means that Dr. Murray bought the death vacancy, and that he calculated upon obtaining the appointment. That his chances of so doing should be spoilt from "on high," owing to the fact of his being of military age, is a scandalous injustice. The high-handed manners of Government departments want careful watching. That we are fighting the Prussians abroad is being made an excuse for imitating them at home. The Local Government Board had neither the right nor

the power to interfere in this matter, but it evidently bounced the Hinckley Guardians into thinking it had. Dr. Murray ought not to let the matter rest there. He has unfortunately now no remedy except the unsatisfactory one of bringing the whole matter into the full light of day by a well-worded question in the House.

Preston Councillor's Facetiousness.

At a recent meeting of the Preston Town Council, the new order making compulsory the notification of measles was under discussion, and, on the question of the fee payable to the doctor for the notification, Councillor Cartmell is reported to have said: "Somehow in these times all the ripe plums fall into the doctor's basket." The reporter in the *Preston Herald* calls this "facetious." It is nothing of the sort: it is merely coarse. "Facetious," according to the authorities, refers to elegant wit. This sort of remark is singularly devoid both of wit and of elegance: it is a form of stupid vulgarity which is all too frequent among provincial jacks in office in their reference to medical men. To call the fee of one shilling a "ripe plum" is doubtless considered in some classes as very funny, and when that fee is regarded as more than adequate payment for the ability to distinguish between the rash of measles and the prodromal rash of smallpox, the plum becomes so succulent as to provoke the envy even of the opulent.

Titled.

W. G. WRITES: "As a now 'constant reader'—with pleasure and profit—of your 'At the Periphery,' may I venture to comment on your present issue? I find there an exact reproduction of my own ideas a little while ago—unwritten ideas on my part—as to the inadequacy of medical honours in this country and the exclusion from the "Upper House" of some of the men who shed most lustre on the national name. But of late I have thought differently. Now I ask myself, 'Is that assembly worthy of them?' and I am sure of the contrary. After all, avoiding extreme views, is not an hereditary honour an anachronism and a very mischievous one? Is not our remedy the remedy of the time—abolish all such. Look at the hereditary nobles of Germany and Austria! Has the world anything more exclusive or anything more vile?"

Another View.

TITUS is trenching upon a domain—the political—which it is my purpose as far as possible to avoid, but I may at least venture to point out that there is another side to the view here expressed. Hereditary titles are, of course, an anachronism, but like a good many other antiquities they lend a certain colour and dignity to life which many of us would be very sorry to be without. I do not go so far as the scion who, in a burst of poetic frenzy in his Oxford days, wrote the couplet which brought him even greater fame than the dukedom to which he ultimately succeeded. It ran something like this:—

"Let art and commerce, wit and learning die,
But give us still our old nobility."

I am nevertheless of opinion that hereditary rank, especially when it is worthily borne—which in this country it usually is—stands for something which lends atmosphere and picturesqueness to a social system which is otherwise for the most part drab and dull and uninspiring. And, if this class is to be maintained and its inevitable gaps filled, some at any rate of the recruits should come from those who have been real benefactors of the human race.

Twells Brex on Dentists.

THE writer in the *Daily Mail* who signs himself "Twells Brex" must add enormously to the popularity of that paper, for he is gifted with a drollery of outlook, a quaintness of expression and a lightness of touch which raise his articles into the highest class of humorous writing. Recently (January 3rd) he had an article entitled "The Woman Dentist—Another Sex Illusion Shattered," which was calculated to provoke mirth in the most pessimistic. "Even when Pullhard silenced me with the rubber gag, I could express myself by spasmodic knee-jerks. Once even I kicked all his strafers off their pivoted tray and gained four minutes' armistice while he collected the fallen." But Pullhard was at the front and his *locum* was a lady, and the writer submitted himself to what he fondly hoped would be gentle mercies. "But I went away with an aching disillusion. If women are, indeed, the tender sex, how can they become dentists?"

On Cab Whistles.

BUT "Twells Brex" can be serious and very incisive when he pleases. Here is a passage from an article (January 7th), "Murder by Cab Whistle":—"The cab whistle is an older nuisance. It has always been a puzzle to Londoners why the cab whistle is tolerated, even by its friend the noise-loving law. The cab whistle is, perhaps, the most callous and selfish ebullition of the individual that modern civilised urban life permits. The scream of the cab whistle is the most piercing and distressing noise that man has invented. Its very intention—a signal, travelling far and insistently—makes it flick the awake, rouse the asleep, and rack the ill of a whole street. And this for one man or woman who is too lazy to walk to a cab rank, or is vulgarly desirous of proving to a hundred neighbours, 'Listen, how many dinner guests I am speeding again to-night!' In these two classes come the majority of the users of private cab whistles. For the cab whistle is an implement of refined torture that no decent inhabitant of a residential street would use except under the stress of a foul night or an urgent call. Its only legitimate use is by porters of offices, theatres, and restaurants in streets without private inhabitants. The good sense and neighbourliness of Londoners have hitherto kept its use to some extent limited. The shortage of taxi-cabs and some strange and sudden decadence in the humanities have made an intolerable misuse of it that is making residential London a purgatory."

Neurasthenia.

THE article which we publish this week from the pen of Dr. Tom A. Williams, of Harvard University, deals with the much-debated question of "neurasthenia" from the modern common-sensical point of view. To plaster a symptom-complex with a name of Greek derivation does not make a disease. The labels which are thus manufactured to satisfy the demands of the laity are all too often instrumental in throwing dust in the eyes of the profession. It is this dust which Dr. T. A. Williams seeks in this article to remove, and I feel sure our readers will be grateful to him for his effort. Writing to our esteemed contemporary the *Lancet* a letter under much the same title as Dr. T. A. Williams' paper, Dr. C. A. Mercier has some very pithy and pertinent things to say which he has apparently said at greater length in an article which the *Lancet* will shortly publish. Anything from Dr. Mercier's pen is always worth reading, and I await the publication of his article with joyous expectation.

CURRENT TOPICS.

Remuneration for Disablement Benefit Insured.

A CORRESPONDENT wrote, under date January 9th, as follows:—"I presume it is too late for you to communicate with the author of the interesting articles on insurance. In the first he states we are not paid for those in receipt of disablement benefit, but Dr. Richmond writes me to say that there is no truth in the statement that practitioners on the panel receive no remuneration in respect of treatment provided for insured persons in receipt of disablement benefit. Which of the two is correct?"

This letter we sent to "Delta," who replied as follows: "Please forgive my delay, but your letter and enclosure arrived with a broken fibula, the former being the more welcome. In answer to your correspondent, the case may be thus stated: Disablement benefit persons pay no contributions, hence nothing goes into the Medical Benefit Fund for them. There are in round numbers 15,000,000 insured. If I have on my list 1,500 of these—really I haven't half this number—I get 1/10,000 of that fund. The Commissioners say that owing to the method of book-keeping I am paid for some number over this 1,500—say, for argument—1,600—and that this arrangement compensates me for the absence of contributions from the class under notice. But this will, of course, apply to every Panel doctor. Therefore the Insurance Committees are paying doctors for 16,000,000 persons instead of the 15,000,000 for which they hold funds in the 'Medical Benefit.' Which is very, very absurd. For no stretch of the imagination can picture the Commissioners paying for more than 15,000,000 insured, if the Medical Benefit Fund only has contributions for that number. I hope this is clear; a broken leg does not clarify one's powers of expression, except in respect to the lesion."

Magistrates on Milk.

ON the public health authorities throughout the kingdom is thrown the responsibility of supervising the milk supply of the people; on the magistrates is thrown the duty of visiting breaches of the law with suitable penalties. Without the activity of these two sets of public functionaries the public has no protection against the fraud of the dishonest purveyor of milk. There is, perhaps, no meaner commercial fraud, and none more dangerous to the health of the most delicate members of the community than the adulteration of milk. It is the infant and the sick person who suffer most, and impure or adulterated milk is one of the potent causes of infant sickness and mortality. We have before now noticed how little support is given by the Dublin magistrates to the praiseworthy efforts of the health authorities to deal with the evil of the adulteration of milk. From the report of the Medical Officer of Health for 1914 it appears that in case after case the penalty inflicted was a more or less trivial fine. Even when the same defendant was convicted twice or three times in the same year, a fine was deemed adequate penalty. Surely the magistrates of Dublin must know that water is cheap, and the sale of watered milk highly profitable, and that a few days' fraudulent trading will go far to pay even a heavy fine. In a case heard a week or two ago, analysis showed the presence of 11.8 per cent. of added water; there were four previous convictions; the defendant was fined £3. Until magistrates are willing to impose the real penalty of imprisonment it is hopeless for health authorities to attempt to cope with the milk fraud. As things are at present, cheating pays.

The Medical Superintendent.

It might be to the advantage of many hospitals were they to adopt a system already existing in some of having a fully-qualified medical practitioner in the capacity of plenipotentiary, so far as general administration was concerned. Such a functionary, in dealing with the clerical work, would be in a position thoroughly to comprehend the direct bearing of his arrangements upon the medical side of the institution. Moreover, in connection with the supervision and control of the resident staff and pupils, his sympathies would be more acute, and his judgments less resented, than we fear is occasionally the case when the secretary or matron take upon themselves the necessity of interference—no matter how just that interference may be. He would fully understand what was essential in the dieting and treating of cases, and could discourage the foolish economy which is too often practised by hospital administrators, in the absence of complete grasp of the features of certain cases. Attention is drawn to this matter by certain instances which have come under our notice, where no matter how good the intention of the matron and secretary, for lack of a broad outlook, such as is gained by a practitioner of some years' standing, the domestic administration and the management of patients by resident staff do not proceed upon parallel lines. Inasmuch as the members of the resident staff are junior and temporary, they either do not interfere at all, or do so unwisely. It would be clearly understood, of course, that such an official would have nothing to do with treatment, which would remain as at present, in the hands of the visiting staff.

The War House Surgeon.

THE manner in which the unequalled resident pupil has risen to the occasion created by the war, is, in many instances, worthy of close attention and high praise. Such men, in several hospitals have been called upon to discharge the offices of house surgeon and house physician, and in those cases which have come under our notice, appear to do so in an admirable fashion, all things considered. One is struck by the thinness of the line which separates the final year's student from the first year's practitioner, and hesitates as to whether it might not be well to perpetuate the scheme by laying more responsibility upon the clinical clerk and surgical dresser than heretofore. In district maternity practice such a scheme exists and is amply justified by results; still more, it might be urged, would it succeed in a hospital where a qualified man, in the shape of the resident medical officer, is to hand. Such an arrangement would necessitate the cutting down of the number of resident clinical clerks, but this might prove eventually an advantage. There would be more efficient discipline, and less shirking of work, inasmuch as no deputies could be found. The system of deputy duty, in a hospital having many clinical clerks, is a continual source of annoyance to house surgeons and hospital porters alike. Under such an arrangement as we suggest, the house surgeon would be set free from much minor work, notably in the extern, and could devote his time to learning more advanced routine of practice. The greater responsibility placed on students in the Irish than in the English hospitals, has had a high educational value, and we could wish to see the system extended.

Export of Cocoa.

AFTER the Lords had passed the Munitions Bill through Committee on Thursday last, their attention was called by Lord Sydenham to the cocoa

exports from this country to the countries of neutrals during the war. An export of 6,638 tons between August, 1913, and July, 1914, had increased to 30,086 tons between August, 1914, and July, 1915. Our total exports of cocoa in the first 16 months of the war had been 33,357 tons, as against 8,883 tons in the corresponding 16 months before the war—an average of 2,000 tons a month during the war and of 500 tons a month before it. Holland, Denmark, Norway, and Sweden had taken between them only 1,161 tons of cocoa in 1913, as against 7,581 tons in 1914 and 15,316 tons in 1915 up to December 21st. The Board of Trade returns showed that our exports to Holland had been 984 tons in 1913, and that they had run up to 5,048 tons in 1914. In the 11 months before the war Denmark had imported 2,211 tons and Sweden 1,550 tons; in the corresponding 11 months of the war Denmark had imported 18,071 tons and Sweden 11,120 tons. He could not see why cocoa, an important food and source of military supply, should not have been made contraband.

This is a very important matter as cocoa is a foodstuff of great value, not only on account of its nutritious power, but on account of its portability. Some of our British houses have consistently advocated, both in interviews with Government Departments and in the Press, the total prohibition of the export of cocoa to Holland, Denmark, and Scandinavia during the war. Messrs. Cadbury Bros., of Birmingham, have made themselves very prominent in this campaign. They are able to point to the fact that their own exports of chocolate during 1915 were of the value of £768 only.

The Suppression of Quackery by the Edinburgh College of Physicians.

In pursuance of their campaign against unregistered practice of medicine, the Royal College of Physicians seeks to interdict the "Dr. Temple Company" from using the title "Dr.," or from pretending that they are doctors, or are persons qualified to practise medicine in connection with the business carried on by them in Edinburgh and Glasgow. After hearing counsel, Lord Dewar, on December 22nd, granted interim interdict, and on January 14th Lord Anderson passed the note for trial of the case in the Court of Session, and continued the interim interdict, but modified it by limiting it to Edinburgh, and excluding Glasgow from its operation. His Lordship said that the respondents' argument was that the curt process of interdict was incompetent, because when Parliament made the use of the title "doctor" by unqualified persons illegal, it at the same time prescribed a remedy, namely, to prosecute for penalties in a criminal process, and that remedy excluded a civil action. The complainers averred that the College was entitled to protect the medical profession generally, and also the right of the public. This was a wide proposition, and his Lordship thought that if it was the complainers' only reply he would have had great difficulty in allowing the process to remain further in court. He, however, proceeded on the point that the complainers had relevantly averred that they were being injured by the illegal actings of the respondents. There was an important question of title to try, and it should be tried by the Court of Session. As the College was only entitled to speak for themselves, and with regard to Edinburgh, he modified the interdict by excluding reference to Glasgow.

It may be remembered that the College has already successfully prosecuted the firm in question under the Medical Act, and that the statutory fines were imposed.

Vital Statistics of Ireland.

It is with regret we notice a further diminution in the amount of information contained in the "Weekly Return" issued by the Registrar-General for Ireland. It is possible that the change is only temporary and due to war conditions, such as the necessity for economy or depletion of the staff. We hope that it is so, but we cannot but remember similar changes made prior to the war, the sum of which has robbed the "Weekly Return" of much of its interest and value. One of the most valuable tables in the return for many years past was the table of figures relating to some twenty or thirty large cities of the world—not only in Great Britain but in Europe, India, Egypt, and America. This table is now gone, and there is no reference anywhere in the return to vital statistics outside Ireland, beyond what is contained in the following two sentences:—"The mortality last week in 96 large English towns (including London, in which the rate was 13.3), was equal to an average annual death-rate of 14.3 per 1,000 persons living. The average rate for 16 principal towns of Scotland was 15.9 per 1,000, the rate for Glasgow being 15.0, and for Edinburgh 15.4." For comparative purposes the return is now quite useless. As the figures no doubt still reach the General Register Office, it seems a false economy to refuse to print them. In other ways the return has become even less informative than heretofore, instead of developing, as it should, from time to time.

PERSONAL.

THE Academy of Medicine in Paris has elected Sir Dyce Duckworth, Bt., M.D., of London, to be a foreign corresponding member.

AFTER 32 years' practice at Fochriw, Wales, Dr. E. Davies, J.P., is now retiring owing to ill-health. He was presented with a gold watch by his patients.

WE regret to learn that Dr. W. J. Potts, Medical Superintendent of the Bethnal Green Infirmary, has been injured in a motor-car accident.

DR. ERNEST PEACHELL, Medical Superintendent of the Isle of Wight County Asylum, has been appointed Medical Superintendent of the Dorset County Asylum at Dorchester.

LIEUTENANT-COLONEL EDWARD LYMAN MUNSON, the well-known authority on problems of military hygiene, has assumed the editorship of the American journal the *Military Surgeon*.

A MEMORIAL to the late Dr. Alexander Graham, who died of wounds received at the Dardanelles, which took the form of an enlarged photograph of the deceased, was unveiled at Stratford last week.

LIEUTENANT-COLONEL DR. ROBERTSON WILSON, J.P., made his first public appearance since he was wounded at the Dardanelles at the Wallasey Police Court on January 13th, where he entered upon his magisterial duties.

MR. WILLIAM TAYLOR, Vice-President of the Royal College of Surgeons of Ireland and Surgeon to the Meath Hospital, Dublin, has been invited to become Consulting Surgeon to the Coombe Hospital in succession to the late Mr. F. S. Heustan.

SIR WILLIAM TURNER, K.C.B., Principal and Vice-Chancellor of the University of Edinburgh, completed his 84th year on January 7th. Migrating to the Scottish capital over 60 years ago, he has long been recognised as a tower of strength to the Edinburgh Medical School, and later to medical education generally as a member and finally as chairman of the General Medical Council.

CLINICAL LECTURE

ON

THE MANAGEMENT OF FUNCTIONAL NERVOUS AFFECTIONS: MODERN METHODS ILLUSTRATED.*

By TOM A. WILLIAMS, M.B., C.M.Edin.

Lecturer on Nervous and Mental Diseases, Harvard University, Washington; President, Washington Society of Nervous and Mental Diseases; Foreign Correspondent, Member of the Society of Neurology, Paris, etc.; Neurologist, Freedmen's Hospital and Epiph. Dispensary, Washington.

THE general idea is that a functional nervous disorder is one in which the physician has been unable to make a diagnosis; and, therefore, by exclusion of structural changes, he calls it functional. Some physicians say that there must be some organic substratum for any disorder whatever, and that we only call it functional from lack of knowledge. I wish to protest against that attitude. So we must begin with what we do mean by functional diseases. Disorders of the nervous system may be divided into two classes:—

First, there are organic, by which we mean disorder of function showing itself in consequence of some actual physical changes in the nervous system itself, even although those changes are only histologically discernible. We are not going to speak now of any such diseases.

Secondly, there are nervous diseases which do not include any actual disturbance of the structure of the nervous system, but are due to a disordered reaction of the nervous system on account of the fact that it is not receiving the proper nutrition necessary for proper activity, or because the excretory conditions are not such as to permit it to metabolise properly. Those, of course, are physical in origin. But there is another kind of disturbance of nervous reaction in which there is no physical disorder whatever, but in which the orderly reactivities of the arrangements of the nervous system into functional systems are not accomplished because of some manner or trend of direction in which they are orientated. These we call psychogenic disorders. An example will best explain the type of psychogenic disorder which we see in the experimental animals with which Pavlov worked on the digestive glands. He tells us how he made the gastric fistula in dogs in order that he might study the flow of gastric juice, and that he subjected the dogs to various influences to modify that flow. The nature of all these influences is psychological. You remember, for example, that a dog normally secretes gastric juice when he is shown a piece of meat, and that one can substitute for the stimulus of showing a piece of meat such a stimulus as the ringing of a bell which the dog has learned to associate with receiving his food, so that when the bell rings, the dog's gastric fistula secretes gastric juice just as when shown a piece of meat. That is a "conditioning" of a reflex; but you can readily see that it is not the ringing of the bell in itself that causes the secretion, but the *idea* that the dog has of the *meaning* of the bell—a psychological process—which causes it to have an emotion of pleasurable anticipation, which leads to the flow of the gastric juice. In the same way he performed the opposite process with a whip by a reverse mechanism, inhibiting the flow of the gastric juice in spite of the fact that the dogs were shown a piece of meat—so powerful was the stimulus of fear from the whip, not by the mere visual elements of a long body with a flexible appendage, a whip, but on account of the fact that that body to the dog

had a meaning—a meaning of apprehension of impending physical pain and fear thereof, and it was the meaning (which is a psychological factor) which prevented that dog from secreting gastric juice.

Those are simple experimental illustrations of psychological processes influencing bodily reactions. We know of Cannon's experiments of proving the effect of fear in causing hyperadrenia in cats, and Crile's clinical work proving that fright can kill.

Now I say these things because they are experimental; because they correspond to some of the clinical facts; in order that there may be no further scepticism as to the real efficacy of psychological reaction.

Now we go back to a study of those functional nervous conditions which have a physical source other than diseases of the nervous system. The prototype of these conditions is comprised in the old "waste-bag" that we used to call neurasthenia. Neurasthenia is a word used in the sense of psychological disturbance by some writers—Dejerine, Raymond—but we are not going to use it in that sense at all. Neurasthenia is a syndrome, often of complex causation, of which exhaustion is the chief feature, accompanied or not by pains and other symptoms. It should not be regarded as a clinical entity. If we take a number of patients who are really capable of being classed in the old neurasthenia, we shall find various types speaking aetiologically. Let us enumerate a few. Most of the cases of so-called neurasthenia can be differentiated into one of the following types: In the first place the middle-aged neurasthenic is nearly always found to have some actual demonstrable physical disorder, and since the use of the sphygmomanometer we find a large number of cases with high blood pressure, and many with renal disorders, even short of the exhibition of hypertension in the blood vessels. Many of us believe that hypertension itself is merely one of the signs of toxicosis, and our reasons for that belief are that in such patients, when they reach a more advanced stage, there are manifestations, clinically and pathologically, definitely due to failure of proper metabolism of proteins. We know in therapy that many of such patients are immediately relieved when there is a limitation of the intake of food protein, and we are beginning to know, since going more into the study, that it may not be a matter of quantity of protein, but a matter of the kind of protein, which to certain persons is toxic in that respect; just as we know there are other than food-proteins which are toxic to various parts of the body. This subject is new and is yet to be worked out in detail, but it is not new that we can by appropriate therapy keep many of these patients comfortable for a great number of years by appropriate dietary.

As an example:—An engineer, 35 years of age, had obsessions. He felt he could not concentrate on his work, believed he was losing his mind, believed it necessary to take a European trip for two years. He had been away for several weeks in the mountains without any benefit, came back to work

* From an address given to the Chicago Medical Society at the opening of their new hall in the Marshall Field Building, October 7th, 1914.

—fell asleep over it, felt discouraged, did not know what the upshot might be. Investigation showed that since leaving active field work he had been employed in a large company, which necessitated staying in town, doing only office work for three months; all this time he had been taking the food he had been accustomed to. Without going into further detail, he had the usual clinical syndrome of disordered metabolism in a robust man. To have diagnosed neurasthenia would have led to most irrational therapy, and yet current custom might have been content with such diagnosis.

The man was given a rational diet with a limitation of protein and over the average amount of the vegetable saline, so that in a week he cleared up perfectly. He did not have to go to Europe, and has been quite well for three years.

Contrast that case with a similar one. A robust man who in the same condition refused to consult a doctor, although strongly urged to do so by myself at the request of his friends, instead adopted Christian Science; believed himself perfectly well, went on with his work, and finished up with suicide, the result of business reverses caused by optimistic rashness at the end of six months for lack of rational medical treatment of a toxic condition. In contrast, I multiply successful cases; but I think every physician of experience has seen examples due to a toxic condition removable by dietary. (1)

Another kind of neurasthenia is the type first spoken of by Dr. Haskell, of Bridgport. He found that a large number of dispensary ambulant "neurasthenics" were in reality, tuberculars, and not altogether latent. A still more striking presentation of the same fact was that made by Dr. Head, of Minneapolis (A.M.A.), who found that even well-to-do neurasthenics were, in a large proportion, tubercular. Dr. Head believes that tuberculosis accounts for many of the cases which Dr. Weir Mitchell benefited by his well-known methods. (2)

Other cases classified formerly as neurasthenics are those having disorders of the internal secretions. We now know a great deal about the clinical manifestations of "nervousness" caused by disorders of the thyroid secretion. Nowhere do we see so aggravated a syndrome of erythism with psychological excitement as in hyperthyroid patients. We know, too, the depression of hypothyroidism, which more particularly in elder people, is often overlooked by careful observers and called neurasthenia. In disthyroidism there are peculiar recurrent states of neurasthenia, great prostration, inability to concentrate, as have been well described by Dejerine, whose book is well worth reading; pituitary disorders too create neurastheniform symptoms. Lastly, there are the cases which I described at the A.M.A. meeting last June, where the insufficient secretion of the adrenal gland produced what I think is the clearest and simplest type of neurasthenia. These patients complain of no severe headache but merely of extreme asthenia, an inability to think clearly, discouragement in consequence, accompanied as a rule by a low blood pressure.

Now the therapy of all these different types, obviously should not be the rough empiricism of the so-called rest cure, which would to many do a great deal of harm; for instance, in a case of toxic-hypertension from poor metabolism, or in any hypoadocrinism, obviously therapy should be directed to the cause of the condition. I am not going, of course, into the details of that kind of treatment, because it is a medical problem we are all to some degree acquainted with, although in some instances the problem has still to be worked out.

Now, lastly, before proceeding to the psychological cases, it is necessary to speak of another physical

condition which we cannot class under any of these heads, which does not create a picture of exhaustion, but which gives rise to a state of general discomfort, restlessness and excitement. That also I believe to be a toxic condition. It is frequently caused by caffeine. It is the type of what the laity calls nervousness or nervous temperament or disposition. It often shows itself in children by a wriggling, a twitching or tic. Psychologically there is the feeling that the time is out of joint; nothing goes right. Later on, if the condition remains chronic, the person never feels right, he feels that things are all wrong, he does not recognise that it is his ideas of reference—that is to say, there is a pessimistic tone and when he finds any circumstances which seem to reflect upon him, or to be unfavourable, he seizes upon that just as a magnet seizes upon a piece of iron. These ideas of reference may become the foundation of paranoia; and we believe that some paranoia may be physical in the first place. Now when a physical condition which may give rise to restlessness, which leaves a jerking for instance, even when this physical state subsides, either spontaneously or from better hygiene, or from medical assistance, the habit which has occurred may persist and the patient who has learned to jerk his shoulder because he has a tight coat may go on jerking his shoulder from habit for the rest of his life. These latter patients then will require for their therapy psychological measures. We shall find later that some of the cases which originated psychologically require for their management physical measures also.

This brings us to a consideration of the clinical types which we most commonly meet which originate psychogenetically. Let us study the mechanism of some of the cases of that kind. A man was referred to me by Dr. Williams, of Boston, because unable to write his name clearly on account of a tremor. This had existed only for one month, and as his occupation was that of a naval paymaster, it necessitated the writing of several hundred cheques a day, and so he feared he might be unable to keep his position. Now the tremor of the hand was not due to an organic condition of the nervous system nor to a toxic condition of the patient. We know tremor is a symptom of toxæmia or of nervous disease. But in this particular case, by finding out that the man is able to draw without trembling, which he could not do if his neurons were diseased or intoxicated, we concluded that his tremor was psychogenetic. We then analyse why writing in particular causes this man to tremble, and we find out that the first time he trembled was when he went back to work after being operated upon and not fit to go back. He was tremulous when he went back to work, and the cheques he signed were refused by the bank, who could not recognise the signature. Apprehension of this caused him to tremble thereafter when attempting to write. This case was published in the *New York Medical Journal* (March, 1911), and the method and management of the case described. The patient was only seen once, and this led to his cure by re-education.

Another case, also of occupational writer's cramp, began in a woman of about 40, referred to by Dr. Little, on the occasion of sickness of her children from scarlet fever. At Christmas time she had to write many letters, and she found herself unable to do so. Formerly she had been proud of her speed in writing, but at the time she was occupied by the anxiety of her children her writing became almost illegible. After she was taken in hand, the mechanism was worked out and the methods of cure established. (3) This patient had been

treated by massage, which I shall call a spurious treatment of functional nervous affection. Many treat by electricity, some are treated by rest of the part—absolutely useless; some by distraction, going away for a change. You can see that none of these measures meets the real issues of not being able to write, and until that is analysed and the patient shown the methods, all other therapy is meaningless and, indeed, it directs the patient to the member which she supposes is diseased from a real source of psychological reaction.

Another most instructive type of functional disorder, often, too, an occupational one, is the traumatic neurosis. (4) Let us again study the situation by a case. A brakeman on the railway, seen with Dr. S. S. Gale, Roanoke, Va., was thrown from a car, his back injured severely, strained and bruised. He was laid up for the better part of a week in consequence. During that time he saw several physicians. The railway physician, of course, told him there was nothing serious in the matter, he would be all right; which opinion was discounted because it was, he thought, to the interest of the railway surgeon not to find anything the matter with him. His private physicians told him there might be spinal disease; and that was the central feature in his mind. Six months later I saw this man: found him hobbling on crutches, in pain, with anæsthesia up to the hips, lost 20 lb. in weight, having a sallow, unhealthy complexion, a dull eye, frequent attacks of weeping and extreme dejection, a hopeless outlook—simply because he believed he was damaged for life. Examination showed there was no lesion of the spinal cord or of the peripheral nerves. His sensibility was not impaired because of any lesion, but was only impaired because he did not believe he could feel. At the one sitting we had the sensation was restored down to the knee. His motor impairment was merely due to his own belief that he could not walk; his emaciation and sallow tint were simply due to the depression of mind in which he lived for six months which hindered sleep, appetite and assimilation. All these would disappear when he ceased to be anxious about his general condition. Now, this man had been treated by reassurance, suggestion, by various drugs, and, possibly, by various physiological applications without any effect whatever. The man was perfectly restored to health in a month as a result of one interview, which lasted three hours, during which the condition was explained to him so that he could understand the mechanism of his disorder. (5)

Another case, without any physical manifestations of disease, such as writer's cramp or paralysis, was that of a farm lad, seen with Dr. A. B. Hooe, ret. 24, who had endeavoured to commit suicide four times, twice in a sanatorium where he was sent to be treated, but there all the attention he received was incarceration and surveillance. Becoming worse, he twice tried suicide there, and was then brought to Washington. There the proper therapy was begun by trying to find the cause of the boy's impulsion to commit suicide. The cause was shown by the analysis of his psychological content. The reason he tried to commit suicide was because he was ashamed of himself, this because he could not make good in life; he believed he was a half-idiot. In school first, and latterly in his youth, and again in managing his mother's farm, which he could not successfully do, and he felt humiliated all the time.

The beginning of the feeling that he was not as other boys arose from the fact that he had been told by other boys that self-abuse led to softening of the brain, and as he had been indulging in self-abuse he became shame-faced, and he lived in this vicious circle until he was 24 years old.

Treatment was conducted in a general hospital, and after this was discovered, and it was all explained to him clearly, in a very simple way, he was given freedom, and in a week left for home, having rid himself of his desire for self-destruction as a result of rational therapeutics.

Another very common functional disorder is nervous dyspepsia. A woman was brought to me by Dr. Jackson because she was becoming more and more anxious, nervous and disturbed, more and more difficult to feed, although she consulted a very well-known gastrologist and was under his care for six months. It was found that this woman was hysterical. I shall not go into the case at length. She had been taken to the gastrologist because she was so thin; she became thin through worry on account of domestic difficulties; but I found that she was so impressed by the opinion that she had a weak stomach, and that she must follow a certain dietary, that it became a fixed idea; her life was a misery about diet; she had the idea that she could not digest, and hence would not eat. (6) The treatment of such cases is not gastric stimulants or general tonics, or physical measures at all; the treatment of these patients is to persuade them that they are in reality capable of digesting nourishment, and it is sometimes very difficult to persuade them, because they are called dyspeptic so often by physicians that they find it hard to believe that the disorder is not in the stomach itself. Those are the cases for whom isolation is most applicable.

Another case where the digestive organs were affected was that of a young woman, seen with Drs. Watkins and Staverly, with pain in the region of the appendix, which had been removed two months before. It was discovered that the pain was, in reality, an apprehension of further pain, and also it was re-enforced by the fact that when she had pain she got morphine, which felt very nice. She was cured in two hours by a physician who persuaded her that the pain was really purely imaginary.

Another patient, seen with Dr. J. S. Stone, with appendicitis of six years' standing, finally was operated upon; but the pain persisted because there was a constant reference by the patient to the region formerly painful, which produced a spasm of the ilio-psoas and oblique abdominal muscles of the right groin. Re-education was started by showing the patient how to relax the muscles affected. (7)

Lastly, we must consider the psychogenic mechanism occurring in children. Those are very common and easy to deal with. A child, seen with Dr. Perrie, of McKeendree, Ma., who had been kept out of school for a year and a half on account of the advice of the doctor that she was too nervous, and on account of the fact that when her mother attempted to teach her one evening the child could not sleep for four or five hours, which seemed to corroborate the opinion that study made her nervous. This child began with a series of tics, which had been removed in a sanatorium; they had been treated by physicians with arsenic in the belief that they were chorea. They consisted of smacking of the lips and bending down, touching the floor. These movements arose from the child's belief, from the physiology she was taught at the age of five years, that her breath was noxious. She had always been taught that she must never hurt others, but that as her breath was noxious she knew a means to offset its hurt by "the healing kiss." She kissed the air which she expired; that was the source of the movement of the lips which had been interpreted as chorea. The touch of the floor: it had lived; nothing living must be hurt, not even the floor. Her heels were hard, they hurt the floor; she would render this harmless

by another Biblical expedient—"the healing touch"; she would touch the floor with her hands. These are beautiful illustrations of what a child mind can evolve of itself. In reality, this child was not "nervous" at all. She was neither apprehensive nor fidgety, nor irritable, nor of a difficult temperament. She was a natural child, the only difficulty being that she was an only child, and her parents had been somewhat over-anxious. It was explained to the parents that the child lay awake after being taught because the parents had let the child see that they were afraid of it—it was by suggestion that the child stayed awake. When the matter was explained to the parents, the child was sent to school, and the child has been going to school ever since perfectly well. (8)

I might mention many more cases, but I shall not enlarge, and in conclusion I have one more word to say. There are many cases in which the discovery of the aetiology is not of great therapeutic importance and where psychological habits show that a particular proceeding is required for their removal—and I want to quote cases of that kind—the first case is particularly striking. This was a man referred by Dr. T. C. Martin because of a grunting noise which he made with respiration while at the same time he bent his body. This was a tic, a bowing tic. I shall not go into the analysis of when and why it occurred. It was not completed. I shall merely trace the method of removal in contrast to the method which had been used. It had been recognised by the physicians in North Carolina that this was a functional affair and possibly psychological and they had used the method of suggestion; it was an absolute failure. They then used indirect suggestion with failure again. They then used a third method of suggestion, indirect by obtaining from a remote country a powerful drug, guaranteed to cure this particular disease. There was no effect. Such means of psychotherapy should be stigmatised as irrational procedures, although they have often succeeded in removing psychological symptoms. My procedure was different. I reasoned that this bowing tic took place because of a sudden contraction of the recti abdominis and that if the patient could be taught control of the recti and of the diaphragm, the movements would necessarily cease. We then started in to show the patient how to perform the contraction of the recti and of the diaphragm—a very simple procedure which he quickly learned. It should be apparent that when the patient was voluntarily moving his muscles he would not perform the tic, and when he voluntarily contracted the diaphragm he could not make the grunting noise. He learned all this very quickly and was cured, having been seen only twice.

SUMMARY.

Now I might extend this list with a number of cases, illustrating rational removals of psychological situations, but my time forbids. I want to say one or two words in summary.

Spurious treatment of functional nervous disorders means any treatment which does not take account of the aetiology or a treatment which taking account of the aetiology applies such a crude measure as "suggestion" to it; or, treatment which, taking no account of aetiology, but recognising it as functional nature, transfers the patient to the alleged therapy of the commercial which is sanitarium, useless and often detrimental, unless the sanitarium is under the management of a neurologist who has made a study of this kind. In sending the patient to the sanitarium, you are really sending him to another man, to whom the sanitarium is incidental. Now, if we treat these patients, psychological cases, by suggestion, or if we treat them by crude, ill-conceived, misapplied physical measures, or by physiological therapeutics

like massage, electricity, distraction, rest, isolation and feeding, we are not doing any better than the people that we are always finding fault with—viz., the Christian Scientists in the name of theology, who treat them by suggestion, not knowing so, or the osteopath and chiropractic, who treat them by suggestion applied in ignorance by means of crude manipulations, without knowledge of the aetiology.

We may cure for a while by suggestion cases which are purely psychological, but this often does a great deal of harm by exalting the patient's suggestibility, which it should be our object to remove in order to prevent future disorders. Now, as to Christian Science suggestion, it is far superior to suggestion that we can give, because it is clothed in the cloak of religion, which gives to it a tremendous appeal; and, secondly, it gives a definite something to hold: "there is no disease," "nothing can be wrong"; whereas medical suggestion merely says "Your arm is not paralysed," "You can speak." This does not take advantage of a universal negation like that of the Christian Scientists, which, after all, has in it something philosophical and is a logical system after all in spite of the illogical presentation in their book. So that, if we adopt suggestion in therapeutics, we are merely using an inferior method which the charlatan can use more effectively. Even massage, a useful means in conditions of asthenia, must be applied in all cases where it is meant to have a definite indication in physical cases, but not used indiscriminately. We then have to distinguish the genetic factor in each case, and when possible to direct our attention to that in order to remove it. When this is not necessary, we must get rid of the effect of that initial cause in cases of physical disorder by the appropriate medical measures we possess, in cases of psychological disorder by creating a mechanism whereby the psychological reactions are re-established in harmony with the environment.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by M. J. Levy-Vallesi, *Medecin aide-major of First Class*. Subject: "Clinical Characters and Thermal Curve of Paratyphoid Fever."

ORIGINAL PAPERS.

MILITARY AND CIVIL HOSPITAL PRACTICE—A COMPARISON.

By HAMILTON G. LANGWILL, M.D.ED., F.R.C.P., CAPT. R.A.M.C. (T.).

To anyone who has had the honour and satisfaction of acting as a visiting physician to a large hospital, the termination of his period of service—even after 15 years—comes with no little regret. The care and treatment of patients in a hospital ward in many ways is so much more satisfactory than is possible in private practice that the regret is natural, apart from any personal feelings in severing a tie of fairly long continuance. What a different aspect the management of any serious case in practice assumes when the patient is removed to your hospital ward. Here not only is there generally the

benefit of a resident doctor for any emergency, but the change of environment to a light and airy ward—with a conveniently accessible bed, constant skilled nursing night and day, implicit obedience to orders and freedom from the well-meant but often far from helpful efforts of relatives—renders the case much more manageable.

It was therefore with no slight amount of pleasurable anticipation that the writer, after some years of cessation of hospital duty, responded to the summons to hospital service when war broke out. For though one had for several years held His Majesty's commission in the R.A.M.C. (T.), this carried no duties with it until mobilisation occurred.

The Hospital, being what is termed a General Hospital, draws its inmates primarily from the territorial troops stationed within a radius of some thirty miles; and since this particular area happens to be fairly strongly garrisoned, there has not been available in the wards such a large amount of accommodation for returning Expeditionary cases as with other General Hospitals situated in areas less thickly occupied by troops. Nevertheless a considerable proportion of Expeditionary men from both the Eastern and Western fronts have been admitted, so that the following notes on military as compared with civil hospital practice are based on experiences of both home and foreign service patients.

The writer desires, at the outset, to make clear that he is writing purely from the *medical* standpoint; his position being that of a physician in charge of medical wards, surgical questions (though naturally bulking largely in a war hospital) do not fall within his province.

The first point of contrast, of course, is the wearing of one's outdoor headgear throughout the ward visit, a practice which soon, however, becomes such a habit that one is rather apt to forget to remove one's cap in a private patient's room!

The organisation of the nursing staff offers another point of contrast. The arrangements for a nursing staff were completely drawn up several years before 1914, the mobilisation order being the signal for calling together those nurses who had been already chosen for the staffing of a hospital of 520 beds. What struck one immediately was the fact that *all* of the nurses were *fully trained*—there were no probationers. Nay more, one found that not infrequently the "sisters" had been holding the position of matron in smaller hospitals, while those now under them had themselves often been "sisters." There was thus to some extent—to use a financial phrase—a "writing-down," so to speak, of the various grades of the nursing staff as compared with their position in civil hospitals. Moreover, in a large civil hospital many of the sisters and senior nurses generally have been trained in the institution itself, so that there is a continuity, if one may say so, in the standard of training, and the most junior "pro" thus grows up in the methods and "atmosphere" of that hospital. Here all was different. Not only was there a nursing staff collected together who had been trained in different institutions, but the junior members of it—themselves fully qualified—naturally did not always readily fall in with the methods of some of the (ex-matron) sisters. Moreover, the resumption by the junior nurses of duties usually allotted to a probationer made no small demand upon their stock of patience. The more recent introduction—to fill the vacancies due to nurses sent abroad—of V.A.D. members who occupy the position largely of probationers in civil hospitals, has, in the writer's opinion, rather been an advantage. There is thus restored that blend of nursing ranks which makes for smoother work-

ing than if a senior is allotted the work of a neophyte.

As regards the class of cases admitted (referring, of course, merely to the medical wards), several points were noticeable. The variety of patients (due to sex and age) met with in a civil hospital was, of course, not to be expected here. No senile and few degenerative cases may occur—one seldom feels an atheromatous radial artery—but in another aspect the cases in a military ward rather resemble those seen in the rounds of general practice. For whereas in a civil hospital, as a rule, only fairly serious cases are admitted, here comparatively slight ailments—*e.g.*, tonsillitis, febricula, vaccination, or skin troubles, will often be found alongside cases of graver disorder. The soldier in tent, billet, or barracks, if "medically unfit" for duty is sent to a hospital, practically no one being treated as an out-patient. The general aspect, therefore, of a medical ward in a military hospital has not that somewhat depressing "sick-bed" appearance which is often noticeable in a civil hospital with its larger proportion of serious or even hopeless cases.

This contrast is further reflected very markedly in the extremely small mortality rate as compared with civil hospital practice, though another reason, of course, for the low mortality, or (to put it another way) the high recovery rate, is to be found in the *age* of the patients. With patients all in the prime of manhood, recently living for the most part a healthy, active, regular, temperate, outdoor life—all of them being (or supposed to be!) picked lives to begin with—one naturally looks for a high recovery rate, even when serious illness attacks them. Especially noticeable is the comparative rarity, in the writer's experience, of the "alcoholic" type in cases of pneumonia, which was so commonly seen in civil hospital practice.

Another reason for the small death-rate lies in the fact that any case which is regarded as hopeless is at an early date sent before a medical board with a view to his discharge, and, if able to travel, the patient then passes out of the wards of a military hospital. When one recalls one's experience in civil wards, the absence of cases of internal malignant growth is also noteworthy, and the importance of the *age* factor in affecting this incidence is shown by the relatively greater frequency with which such cases as do occur are to be found amongst men in the National Reserve—*i.e.*, mainly over 45.

It is not to be inferred from these remarks that in the medical wards of a military hospital only trivial or uninteresting cases are to be found. On the contrary, apart from the special interest of what one may call "war diseases" (trench-feet, "gassing," etc.), a wide variety of ordinary cases occurs. Especially is this the case in a General Hospital, which draws a large share of its inmates from troops stationed in the neighbourhood. Acute cases of illness (*e.g.*, pneumonia, pericarditis, cerebrospinal fever, etc.) naturally are not to be looked for in the list of *medical* cases brought back in our hospital ships and trains, a large proportion of whom are patients with more chronic, non-pyrexial affections, *e.g.*, sciatica, chronic bronchitis, dilated heart, or convalescing cases of postfebrile debility.

Cases which come under the vague category of indigestion form a very large class, and are amongst the most difficult to deal with satisfactorily. The truth of the saying that "an army marches on its stomach" is constantly borne in on the physician in a military hospital. The men with dental defects—often a broken or missing dental plate—can have their gastro-intestinal troubles, to some extent at least, lessened by appropriate dental treatment; just

as others with decayed stumps can—if they will!—have their digestion improved by removal of these followed by suitable artificial dentures. But there is a much larger proportion of patients whose digestive troubles cannot thus be overcome. So long as they are inmates of a hospital, on suitable light diet, they can usually be relieved of their discomforts, but the difficulty of their *future* dietary still remains. Army regulations do not provide light diet for men *on duty*, but only for those in hospital who are ordered it. Whereas, then, a *civil* case of chronic gastric trouble, returning from hospital to work, can continue at home his light diet and so get along satisfactorily (if not perfectly comfortably), the *military* dyspeptic, on returning to his unit, is supplied no longer with light diet, but with the ordinary rations. Now, with the quality and quantity of this no fault can be found (though the cooking of it in certain circumstances may not be always of the best), but for digestive organs that cannot assimilate beef or mutton—even when well cooked and daintily served in hospital—the ordinary army dinner proves impossible. For such patients it is not “light duty” that is required so much as “light diet” which would enable them to continue to perform ordinary duty. One finds that a large number of the recently mobilised Territorials and Kitchener’s Army men have for years, when in civil life, lived upon light diet and regularly carried through a hard day’s work upon this, and it is a pity that, on joining the Army, such men should be required to spend so much of their time in hospitals and convalescent homes because of their inability to obtain in barracks a diet which they can digest. A “light diet section” of a regiment—with fare provided accordingly—is doubtless too much to expect; but instead of being recommended by a board, after repeated spells of treatment in hospital, for discharge from the Army, might such men not be utilised by being transferred to duties in connection with *hospitals* in which light diet, or mince, is being provided regularly as part of the daily fare? Such “light diet” men, of course, would be of no use for a draft for foreign service unless they were transferred to another hospital unit where similar facilities could be obtained.

Before passing from the subject of digestive disorders, the writer would allude to a condition not infrequently seen in patients who have been “gassed,” viz., the occurrence of an intractable form of retching or vomiting, occurring almost daily. Sometimes the retching had no apparent relation to the presence of food in the stomach, in other instances dinner especially would be rejected. In most of the cases even of long duration it was noteworthy that there was very little evidence of emaciation, so that apart from a certain depression of spirits (sometimes very marked) the man *looked* little the worse.

The great advantage in hospital practice of the methodical and punctual carrying out of orders has already been alluded to, and in a military hospital with all its discipline one might expect this to be even more marked, since the physician pays his ward visit in the position of an officer. And undoubtedly the appearance of a military ward, with its “out of bed” patients standing promptly to attention at the entry of the physician, gives an aspect of smartness which is lacking in a civil hospital. But there is another side to the picture. Paradoxical though it may seem, in a military hospital the physician or surgeon in charge of a ward (even though he may be a Lieut.-Colonel) is not able to exercise over the most newly-joined recruit the power which is vested in any visiting

“chief” of a civil hospital! Thus whereas in a civil hospital any patient who declines to have carried out some method of diagnosis or treatment thought necessary (*e.g.*, passing a stomach tube, or tooth-extraction in pyorrhoea, etc.), can be at once dismissed from the ward, this procedure cannot be adopted in a military hospital. The civil patient can be dismissed, and knows he will be, for declining diagnostic measures or treatment advised for him, but the military patient can only be dealt with (by sending him back to his regiment for punishment) for *disobedience* to orders (*e.g.*, smoking if forbidden, getting up if told to keep bed, etc.), not for refusal to allow the doctor’s orders to be carried out.

The importance of this difference will be still more appreciated if it is borne in mind that whereas in a civil hospital no patient has any power over another, in a military ward the senior non-commissioned patient in a ward is partly responsible (with the “sister”) for the discipline of the other patients. The effect in a ward, therefore, should *e.g.*, a sergeant decline to allow the carrying out of some medical measures ordered for him can thus be realised. A recalcitrant patient in a civil hospital can be at once dismissed and his influence thus absolutely got rid of; not so the military “passive resister.” He can be sent back untreated to his regiment, but if he is still medically unfit for duty he will be returned.

It must be borne in mind also that in civil hospitals patients are all there from their own choice, whereas a military patient may be sent there against his wishes, *e.g.*, for observation or with a view to treatment to make him more fit. Nay more, the man may wish to get out of the Service, and therefore not only decline treatment which would improve his fitness, but may be rather inclined to exaggerate his symptoms so that he may be discharged. This, however, would lead on to a consideration of the difficult question of malingering which is outside this article, for that is one aspect in which civil and military hospital experience alike present points rather of similarity than contrast.

DIET AND THE CARE OF CHILDREN'S TEETH.

BY SHELDON FRIEL, M.DENT., ETC.

ERRORS in the diet of children are the chief cause of early dental decay, and of malformation of the jaws, which result in irregularity of the teeth and facial disfigurement. It is hardly necessary to point out that food cannot be properly masticated if the teeth are decayed or irregular. Insufficient mastication is a fruitful source of indigestion.

DIET.

If we compare our food with that of barbaric nations, whose teeth are for the most part beautiful, sound and regular, we notice that their food is not soft and sticky like ours. It is owing to the stickiness of our food that particles ferment and produce substances which eat away the enamel and cause decay; and as our food is soft and friable when taken into the mouth, little exertion on the part of the jaws to chew it is required. If an organ is not exercised it does not develop, and unless a child’s jaws are exercised they do not grow sufficiently to allow the teeth to erupt in a regular line.

To resume entirely the diet of our early ancestors is out of the question, but it is quite possible by a change in the nature of our food, and in the order in which the various articles of our meals are eaten to prevent the onset of decay and irregularities.

The refinement in the preparation of foods, so

that all fibrous and coarse particles are eliminated; the enormous consumption of sweets and biscuits; the want of contrast in the taste of different articles of diet; and the number of meals and "bits" are the chief faults in our modern diet.

GENERAL PRINCIPLES OF DIET.

When the temporary teeth erupt, Nature has designed that the infant should no longer be fed wholly on milk or liquid foods, but on something that requires chewing, as a crust of bread. The child's own instinct, just like a puppy's, is to be always chewing at something, and it is unwise so to prepare all its foods that it has only to give a squeeze of the food between its tongue and palate before swallowing it. By such a method of mastication the food is swallowed without sufficient admixture of saliva, and without any exercise leading to the development and growth of the jaws. It is just as necessary to exercise the jaws as any other part of the body. It is infinitely easier to teach a child of nine months the habit of proper mastication than a child of four or five years, who has already acquired the habit of not chewing.

The majority of foods have a more or less neutral taste which does not tend to a large flow of saliva, therefore it is advisable that there should be a contrast in the taste of the articles of a meal—*e.g.*, beginning the meal with a radish and ending with fruit or savoury.

The liquids of a meal should be reserved to near the end, as they inhibit the flow of saliva and gastric juice. The habit of "bite and sup" is very harmful.

It has been found that any mild acid produces a copious flow of saliva, which tends to neutralise the products of fermentation from the little bits of food remaining around the teeth, which products cause decay. For this reason fruit is strongly advised to be eaten at the end of every meal.

Too much emphasis cannot be laid on giving foods that require mastication to children over nine months old.

The following diet is suggested:—

Breakfast.—Porridge, made out of whole oatmeal or "pin meal." It is better than Quaker Oats, Flake Oatmeal, or Hominy.

Grape Nuts, Shredded Wheat, Force or Rusk as a variety occasionally from porridge.

All these with stewed fruit-juice or jam, or sugar and butter, but *not* flooded with milk, as no chewing is then necessary, and there is very little distinctive taste to stimulate a flow of saliva.

Fish, meat, bacon or eggs. If meat is cut up, it should be cut in flat squares about one inch square. It necessitates mastication. Minced meat is not advocated.

Fried potatoes—not mashed potatoes.

Home-made brownbread, toast, pulled bread. No fresh bread; all crusts to be eaten.

Butter. Jam (home-made, if possible).

Diluted milk. Tea, very weak, three-quarters milk.

At the end of the meal a small portion of fruit should always be eaten. Fresh fruit is better than stewed. Apples and oranges are best. Half an apple is quite sufficient.

Lunch at School.—Sandwiches, bread and butter, jam. Cocoa, diluted milk or water, soup as a drink.

Small portion of fruit.

Dinner.—Hors d'œuvre. Very small portion of anything with a very distinctive taste. This is specially advised for children over ten years of age. Vegetable relishes in preference.

Soup. It is of very little nutritive value, and being a liquid, it comes too early in the meal. The very common dinner of bread and soup is not the thing for children. To prepare this is, unfortunately, so easy that it forms the main part of the meal.

Fish, meat, fowl, eggs—no mince.

Vegetables—not mashed up.

Raw vegetables as celery and salads are excellent.

Potatoes, boiled or baked, not mashed.

Plain puddings—not sloppy. Milk puddings, as rice pudding, twice baked.

Stewed fruit.

Savouries; small portion with distinct taste.

Water, diluted milk, home-made lemonade, lime juice.

At the end of the meal always fruit, fresh or stewed.

N.B.—At the end of every meal fresh or stewed fruit should be eaten.

Tea.—Bread—pulled, toast, home-made wholemeal, or baker's bread, not fresh.

Eggs.

Butter.

Jam, home-made if possible.

Tea, very weak, or diluted milk.

Fruit.

Supper.—If any is taken, to consist of a little fruit. Biscuits are not advocated, as they crumble into such fine powder and stick in crevices around the teeth.

It is quite possible that if the whole diet were changed suddenly the child would suffer from indigestion, but if the change is made gradually during three weeks, no ill effects whatsoever should follow.

CLEANLINESS.

Owing to the finely powdered and sticky nature of so many foods, it is necessary to clean the teeth by artificial means, night and morning. If appliances to correct irregularities of the teeth are being worn, it is necessary to rinse the mouth after each meal. In brushing the teeth, a small brush with fairly hard bristles of uneven lengths should be used. The teeth are brushed in every direction, especially up and down to remove the particles of food between the teeth. The outside of the back teeth should receive special attention.

The following routine is advised for everyday use:—

The mouth first to be rinsed with a small mouthful of the following wash recommended by Mr. Pickerill:—

Potass. tart. ac., gr. ii.

Sodii chloridi, gr. ii.

Aquam, ad oz. i.

The teeth then to be brushed with plenty of warm water and no tooth powder, and finally the mouth to be well rinsed with a mouthful of another solution of Mr. Pickerill's, designed to induce a flow of saliva:—

Potass. tart. ac., gr. ii.

Ac. tartarici, gr. i.

Ol. limonis, m. iii.

Aquam, ad oz. i.

No rinsing with water after this to take the taste away. The same procedure at night time. After each meal the mouth is to be well rinsed with warm water, and then with a mouthful of the second solution. This is especially advisable if appliances are worn in the mouth. It is important to see that each step is carried out regularly each day till the process becomes a "habit."

SWEETS, BISCUITS AND CAKES.

There is no doubt that the constant eating of

sweets and chocolates is most injurious to the teeth and general health, and it is strongly advised that none be eaten between meals. The giving of sweets or biscuits to children just before they go to sleep is pernicious, as it allows the solution of sugar and particles of biscuit to lodge in the interstices of the teeth, and the fermentation products of these substances promote decay. The least harmful of sweets are "acid drops." Money spent on sweets can be devoted to fruit.

BREATHING.

Mouth breathing is one of the greatest causes of irregularities of the teeth. Infants and children should always keep their mouths shut at night time, and if they find it is not possible to do so, the nose and throat should be examined to discover the presence of adenoids or other obstruction.

HABITS.

Such habits as sucking fingers, piece of blanket, comforters, or biting the lips, are injurious to the teeth and should be stopped at once. If they are allowed to continue for some time it is extremely difficult to stop them.

DECAYED TEETH.

It is advisable for children to be brought to their dentist every four months to see if there are any decayed teeth. It is much simpler to fill a small cavity than a large one and not so painful. When a tooth starts to ache it is often too far gone to fill. If irregularities of the teeth occur, they should be corrected without delay, as they are more difficult to treat later. The preservation of the temporary or "baby" teeth is important, for if a temporary tooth is lost prematurely either by decay or extraction, the space for the permanent tooth closes up, and there is no room for the latter when it erupts.

GRAVES' DISEASE AND SYMPATHICECTOMY.

By ANDRE CHALIER, M.D.,

Of the Faculty of Medicine of Lyons.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

At a time when the tendency to resort to operations on the thyroid gland for the relief of Graves' disease is becoming more and more pronounced, it may not be out of place to insist once again, with additional cases in hand to support my thesis, upon the advantages and good effects of partial resection of the cervical sympathetic in accordance with the method introduced by the late Professor Jaboulay.

Here is a young chemist's apprentice who has been under medical observation ever since the outset of his disease, and has been treated by several hospital physicians. Notes of his case were published by Dr. R. Lepine in the January, 1910, number of the *Revue de Médecine*. He was suffering from a severe form of Graves' disease with quite a small goitre but extremely pronounced tachycardia and marked exophthalmos, intense tremor and striking nervous disturbances.

After undergoing treatment in vain by innumerable drugs, radiotherapy, etc., Dr. Jaboulay, in December, 1911, performed double resection of the superior cervical sympathetic ganglion, in two sittings. The operative sequelæ were quite uneventful, the temperature never exceeding 102.3° F., and from that time he steadily improved; so much so that about three months after the operation the subject, who had been obliged to relinquish work of every kind, was enabled to resume his occupation, feeling, as he remarked, better than ever before.

At the present time, two and a half years after the bilateral sympathicectomy, he may be regarded as completely cured, and were it not for the exophthalmos, which has diminished but slightly, it would be impossible for anyone to discover any trace of the affection. As you see, he is "well nourished," without corpulence, his mind is quite clear, the heart is quiet and regular, and his hand is free from the slightest trace of tremor. To employ his own words—which express the opinion of those best acquainted with him—he is "quite another man." Here, then, is a case which practically can be looked upon as a complete, permanent cure of two and a half years' standing, to be added to the long list of similar cases comprised in my paper in the *Lyon Chirurgical* in 1911.

The second case is that of a woman, 27 years of age, sent to me by Dr. Plauchu. Here, again, the case was one of typical Graves' disease in which all the cardinal signs of the syndrome were present and several of the accessory symptoms.

On May 7th last, under general anæsthesia, I performed resection of the upper part of the left cervical sympathetic in accordance with Dr. Jaboulay's *technique*; that is to say, I made a long retro-sterno-mastoid resection, cutting through the soft parts, lying on the mastoid process right down to the bone. In doing this I cut through a big vessel giving rise to sharp bleeding. This turned out to be the enormously dilated mastoid emissary vein, which was the size of a penholder. As the vessel had been cut rather obliquely just where it quits the bony canal it could not be seized with forceps and ligatured. The mastoid aperture, through which it passed, was itself rather large, since it admitted without difficulty the blunt end of the largest pressure forceps. The bleeding was temporarily arrested by means of a plug held in position by an assistant. The rest of the operation went off without let or hindrance, and as soon as the sympathicectomy was done the plug was taken away, whereupon the bleeding set in as freely as before. In vain did I endeavour to arrest it by plugging the mastoid orifice with catgut; the catgut was pushed out. It then occurred to me to have recourse to "muscle hæmostasis" introduced by Cushing. A cubical fragment of the sterno-mastoid muscle was removed and pushed into the mastoid canal. This "muscle stopper" was kept in position with the finger for a few seconds and then fixed *in situ* by the aid of two or three sutures, bringing together the soft parts—periosteum, aponeurosis and muscles over it. From that moment the bleeding ceased and there was no recurrence. The operative sequelæ were uneventful, and after the fourth or fifth day the patient began to feel better, and was really better both objectively and subjectively. This improvement has steadily proceeded since that time, so that I anticipate shortly being in a position to class the case as a definitely successful one.

Apart from the interest of this case as bearing on the method which I recommend, it presents a special point of interest in that the patient presented an enormously dilated emissary mastoid vein, though this fact ought not to cause any surprise in view of the usual vaso-motor disturbances associated with Graves' disease. In addition to this was the mastoid anomaly exemplified in the unusual size of the mastoid venous canal. It also shows the advantage to be gained from using the "muscle plug" in cases of bleeding which happens to be difficult to control.

I do not, of course, deny the good results to be obtained by thyroidectomy in cases of Graves' disease associated with a big goitre; in such cases, indeed, the latter operation is to

be preferred. But *cæteris paribus* I feel convinced that for everyone who is familiar with the surgery of the neck, resection of the superior cervical ganglion of the sympathetic will appear easier and, operatively speaking, milder than thyroidectomy, which necessarily remains less methodical, less identical in all cases, and exposes the patient to serious accidents, more particularly to pulmonary complications and hæmorrhage. Then, too, I feel very strongly, from the experience of the cases I have met with and followed up, that the immediate and remote effects of thyroidectomy are less satisfactory than those of sympathicectomy. I can recall two cases of the kind in which the patients were thyroidectomised by Dr. Jaboulay two or three years ago. In one case, that of a young woman, in which we had removed part of the thyroid we saw her on several occasions afterwards, and the portion of the gland removed was gradually being reconstituted, until ultimately it was larger than before the operation. With this thyroid regeneration, the nervous disturbances which had at first improved after our intervention returned. I proposed sympathicectomy in this case, but the patient refused it, having lost faith in the value of surgical interventions for the cure of the disease. I also saw recently an upholsterer, 50 years of age, who was thyroidectomised two years ago, yet he is subject to recurring attacks of nervous excitement, tachycardia and depression the like of which I have never met with after sympathicectomy.

In Dr. Jaboulay's statistics I only remember one case of sudden death after sympathicectomy, and in that instance *post-mortem* examination showed marked hypertrophy of the thymus, to which the fatal result was, in my mind very properly, ascribed. I do not attach much importance to hypertrophy of the thymus in Graves' disease in spite of the, in several respects, contradictory works of German authors on the subject. I have made careful search for evidence of hypertrophy of the thymus in twelve sympathicectomised or thyroidectomised patients, by radioscopy and by percussion, without succeeding in satisfying myself of its existence. I have even examined the bodies of several patients who had suffered from Graves' disease after death from the (unoperated) progress of the disease, without in any one instance finding a hypertrophied thymus gland, so that I fail to see any valid reason for aggravating an already grave operation by a concomitant operation on the thymus.

In conclusion, since we are by no means in possession of certain knowledge of the pathogenesis of Graves' disease, why should the majority of surgeons look askance on the operation of sympathicectomy, which, after all, is physiologically a perfectly logical operation; one, too, which, in most instances, yields excellent results.

SOME BRITISH MEDICAL MEN OF LETTERS.*

PART II.

By W. H. MAIDLOW, F.R.C.S.

(Concluded from page 32.)

JOHN KEATS is the poet-medical student of the last century. We know he was apprenticed to Dr. Hammond at Enfield, and in 1813 worked at Guy's and St. Thomas's, where he mixed a good deal of poetry with his medical studies. He got a medical (a) qualification in 1815, and seems to have kept up throughout his too short life some little interest in medicine—quite enough, indeed, to realise the import of his own symptoms. But inclination to literature, and his disease, pulmonary tuberculosis,

soon made him abandon the active practice of medicine; travelling in search of health, and, with an unreturned love for Fanny Brown, he died unmarried at the age of 26 in the arms of his friend Severn at Rome, on October 23rd, 1821. Whilst at Guy's he wrote "La Belle Dame Sans Merci."

"Oh what ails thee, knight-at-arms,
Alone and palely loitering?
The sedge has withered from the lake
And no birds sing."

He left us the lines:—

"Beauty is truth, truth beauty:
That is all we know on earth and
All ye need to know."

And his immortal "St. Agnes' Eve" (January 20th):—

"St. Agnes' Eve, ah! bitter chill it was—
The owl, for all his feathers, was a-cold;
The hare limp'd trembling through the frozen grass,
And silent was the flock in woolly fold;
Numb were the Beadsman's fingers, while he told
His Rosary, and while his frosted breath
Like pious incense from the censor old
Seem'd taking flight for Heaven, without a death,
Past the sweet Virgin's picture, while his prayer
he saith."

The famous OLIVER GOLDSMITH was born at Pallas, Ireland, in 1728, the son of a cleric, probably the prototype of the "Vicar of Wakefield." After trying various forms of occupation he went to Edinburgh to study medicine, but soon left Edinburgh for the great European tour, with little more than a penny in his pocket. He always said he obtained an M.D. of Padua, but this is extremely doubtful. Returning to England, he made some vain endeavours to practise medicine; was rejected by the R.C.S. in 1758. On one occasion was urged only to treat his enemies! He finally gave up all idea of medicine and got some humble literary work. Then he attracted the attention of Dr. Johnson, who retained till the end a great affection for him. He became one of the original nine members of the Literary Society and in the first rank of writers. He died in 1776, £2,000 in debt, which Dr. Johnson said showed him to be a great man. A warm-hearted, generous man, full of genuine love and pity for humanity, his writings possess that native charm of style so difficult to acquire by mere learning or education. Johnson wrote for his epitaph in Westminster Abbey in Latin:—"He touched nothing which he did not adorn." He has bequeathed to us "The Vicar of Wakefield" and "The Deserted Village," amongst other great works.

"At church with meek and unaffected grace
His looks adorn'd the venerable place,
Truth from his lips prevailed with double sway,
And fools who came to scoff remain'd to pray."

You may remember the story of Johnson selling the MS. of the "Vicar of Wakefield" for £60 to pay Goldsmith's debts to his landlady.

JOHN WOLCOT, better known as "Peter Pindar," deserves passing mention, although his literary work is now read chiefly by people who stumble across it or collect the quaint. Devonshire claims him and his several ancestors who had practised medicine before him. He was born at Dodbrooke in 1738, qualified M.D. Aberd., went with Sir William Trclawney to Jamaica, where he seems to have acted in the varied capacity of doctor, secretary, chaplain and steward. Once the King of the Mosquitoes asked for more alcohol. "Your Majesty is drunk already." "Me drink the whole ocean!" replied His Majesty! When there was the scantiest of congregations, or he wanted to get off for some sport, they would buy off what might have formed a quorum. People would come in order to be "bought off" when this became known. As can

*A paper read before the Thimister Literary Society.
(a) I find this is not so.—W. H. M.

be read in his "Physic and Delusion," he had no great affection for medicine.

One of his claims to fame, and his best, is his discovery of the artist Opie. Him he introduced to London as the "Cornish Wonder." He was, too, patron of another Cornishman, Bone, the painter in enamel.

Wolcot died at Somers Town, 1819.

ERASMUS DARWIN, who lived from 1731 to 1802, deserves also mention. He is remembered now chiefly as the grandfather of the great "Charles," the apostle of the theory of evolution; but the grandfather also was an exceedingly great man. He foreshadowed the evolutionary theory in his long poem, "The Lives of the Plants."

The Darwins are a most remarkable family of geniuses. The son of Erasmus was a physician above the average, and his grandson was the immortal Charles Darwin, who had two sons—one a professor of astronomy and the other professor of biology—both of them F.R.S. They intermarried with the Wedgwoods of pottery fame, who were related to the Hollands, who were related to Mrs. Gaskell; and Sir Douglas Galton, the great eugenicist, is another member of the family.

The works of CHARLES LEVER, who practised medicine in various parts of Ireland and in Brussels, are not much read now; but in my boyhood "Harry Lorrequer" and "Charles O'Malley" were standard books—books full of rollicking humour, a wealth of anecdote, and a rarely flagging vivacity.

FRANCIS THOMPSON, mystic, who must not be confused with James Thomson, pessimist, author of "The City of Dreadful Night," does not come next in chronological order, but he belongs to the group of three who had but comparatively little to do with medicine. Like Keats, his life was saddened by disease, and, like De Quincey, Coleridge and Rossetti, he became the victim of certain drugs not conducive to the health of a normal citizen, manifestation though it may be of the waywardness of genius. As a youth he was sent to Owens College, Manchester, to study his father's profession of medicine. But all went wrong, and medicine as a profession was abandoned. He was left stranded on the rocks of disease, and was discovered in the streets of London selling his poems and hawking. Kind friends restored him to some health and happiness, but he died, aged 48, just as he was becoming known outside his own little circle, in 1907. This is how he was once helped in the street:—

"I waited the inevitable last,
Then there came past
A child like thee, a spring flower
Fallen from the budded coronal of spring,
And of her own scant pittance did she give
That I might eat and live,
Then fled, a swift and trackless fugitive."

His finest piece of sustained writing is, of course, his "Hound of Heaven." In this one can see all his qualities standing revealed—his amazing exuberance, mountains of mystical detail, fertility of imagery, and his mastery of metrical effect, as Mr. Chesterton says somewhere, "his sudden and sacred blasphemies."

"I fled Him down the nights and down the days,

I fled Him down the arches of the years,

I fled Him down the labyrinthine ways

Of my own mind; and in the midst of tears

I hid from Him, . . .

From those strong feet that followed, followed
after."

DR. MACBETH MOIR (1789-1852) was the famous "Delta" of Blackwood's Magazine. He faithfully performed his work of medical practitioner in Edinburgh, where he was well known. The four hundred poems he wrote are now out of fashion; but his "Life of Mansie Wauch" is one of the rather celebrated books of genuine sketches of Scotch

character. I must say, however, I have tried to read it without success.

I will conclude with a sketch of the life of one of my favourites, Dr. JOHN BROWN, the author of "Rab and His Friends" and "Marjorie Fleming." I think I could interest you a whole literary evening in the life and work of this man, than whom no gentler or kinder soul ever lived. Goodness of a broad human kind, free from all feebleness and conventionality shine through the pages of his works.

Born in 1810, he became M.D. of Edinburgh in 1833. He was the descendant of three generations of learned ancestors. The celebrated Syme, probably the surgeon in "Rab," was the first master for whom he ever felt the greatest respect, both as a man and a surgeon. His practice was never extensive, for he was too retiring and never a seeker of popularity. But he was loved and respected by all who knew him as a faithful friend and physician in whom all secrets were safe, whose ear was never deaf to sorrows and anxiety, whose visits were like a gleam of sunshine.

Mrs. Seller wrote of him: "No one had such delight in such a variety of human qualities than he—provided only they were genuine. The rugged humour of a carter, the grace of a high-bred woman, the wit of a man of the world, the innocence of a child—all were dear to this man who was dear to God." She goes on to say: "More than once when I have been prostrate in the dark with headache I have sent the message, 'Mrs. Seller's compliments, and she is too ill to see the doctor' (a joke which he was constantly retailing against himself). I waste little of his visits on professional talk."

It was after his marriage in 1840 that Dr. John Brown drifted, as it were, to writing, but at no time did it interfere with his main life's work—that of medicine.

Thackeray, at a dinner given in his honour, spoke of him thus:—"I know you will join with me in acknowledging the worth, kindness and goodness of a gentleman you all know, and whose goodness I shall always remember."

He kept up his interest in medicine to the end of his life. To him the Great Consoler came in the evening of his days when all the shadows of his life seemed to have resolved in tranquil shade.

Swinburne wrote:—

"He had gone to some happy island in the Elysian Sea,

Where Rab may lick the hand of Marjorie."

Everyone must read "Rab and His Friends" and "Marjorie Fleming." Three of his great medical tenets were:—

(1) The doctor should be able or willing to cure us—that is what he is here for.

(2) He should be sincere, attentive and tender, keeping his time and our secrets.

(3) He must tell us all that is good for us to know and no more.

What Landseer is upon canvass, Dr. John Brown is upon paper. The canine family was never so well represented in literature. I regard him as one of the best exponents of this essay. He was not only a good doctor but a good man of letters. Now he is where "Beyond these voices there is Peace." Keep his "Horæ subsecivæ" in your bookshelves in memory of him.

In conclusion, I have, pageant-like, shown you a procession of medical men who were in their day, and still are, more or less famed for their intimate association with English literature. To some extent they throw a light also on the history of medicine which may be not without interest. The power and originality of modern medicine, the vigour and success with which it has opposed scientific methods of observation and experiment to

the old reverence for systems, inevitably tend to create some contempt for medical history—a half-confessed feeling that we are the men and knowledge was born with our generation. But study the history of medicine, and those of us who are so apt when in health to cast unmerited ridicule or sarcasm on medical aid, and so readily when health fails to run after every new "cure," will find history repeating itself. What is new is not always true, and is often discarded by many as "tried and failed."

By such a study also we learn something of the nature and complexity of medical problems, something of the labours of those great men who have by slow and painful steps advanced the bounds of knowledge. In the words of the great Laureate of Medicine, O. W. Holmes:—

"Always striving in the unequal contest with the hundred-armed Giant who walks in the noonday and sleeps not in the midnight.

"As Life's unending column pours,
Two marshalled hosts are seen,
Two armies on the trampled shores
That Death flows black between.
One marches to the drum-beat's roll,
The wide-mouthed clarion's bray,
And bears upon a crimson scroll
'Our Glory is to slay.'

"One moves in silence by the stream
With sad yet watchful eyes,
Calm as the patient Planet's gleam
That walks in clouded skies.
Along its front no sabres shine,
No blood-red pennons wave;
Its banner bears that single line—
'Our Duty is to save.'

Both armies indeed fight to save. Who shall say to which the greater glory?

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

QUACKERY AND THE ETHICS OF JOURNALISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—One of your correspondents suggests that I "try to get at the root of things"; but surely this is not a singular attitude among men of science, least of all among medical men of science. I know not whether there still exist any *bona-fide* followers of that pre-scientific dreamer Hahnemann—whether there are still to be found men, who, having undergone a medical education can yet believe that the symptoms constitute the disease and that by suppressing the symptoms they can put an end to the malady. Scientific medical men note and weigh signs and symptoms in forming a diagnosis, and although they may with caution often attempt to alleviate suffering by treating pain or discomfort with an anodyne, they know very well that in doing so they are not touching the *fons et origo mali*. Morbid signs and symptoms can be done away with only when we have put an end to the pathological processes, of which they are the manifestations. The observations which apply to a single person apply also to the social maladies of the people—what we call the body politic. There exists some deep-seated malady at the root of the symptoms of what is now called neo-commercialism—a cult, the votaries of which devote themselves to the acquisition of wealth by every foul means, undeterred by moral considerations and constrained only by fear of condign

punishment. Signs of this malady of the body politic, of which I do not pretend to know the nature, are found in the work of the City shark and in the performance of medical quacks of all denominations. Neo-commercialism is a contagious moral disease. We cannot at present cure it. We can deal with it only as we deal with certain infectious diseases of cattle, namely, by stamping it out. We can stamp it out by constructing the simple laws which would make punishment for these crimes swift and certain. It is said that the receiver is worse than the thief, but it is quite certain that if there were no thieves there would be no receivers. Once put down quackery and the careers of those who share its plunder, including hypocritical newspaper proprietors who pose as lay preachers of morality, whilst amassing wealth by knowingly conniving at fraud, would be at least beneficially curtailed. Finally, I would personally thank you for the persistency with which you have kept this subject to the front. My knowledge of it and my recognition of its importance have been entirely acquired from the reading of your paper during the six or seven years I have been a subscriber. I thank you especially for so forcibly drawing attention to the report of the Select Committee on Patent Medicines. This document, with the evidence of witnesses, forms one of the most interesting pieces of literature that have appeared during the past eighteen months. It is to a large extent made up of real "human documents," and should be of absorbing interest to every latter-day sociologist.

I am, sir, yours truly,

A STUDENT OF SOCIOLOGY.

January 14th, 1916.

THE DISCOVERY OF AN-ESTHESIA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Permit me to thank you for your favourable editorial notice of my contribution, "C. W. Long," and to say that I think that W. T. G. Morton's part in the introduction of anaesthesia is absurdly overrated, and is almost wholly due to the enthusiasm begotten of the successful anaesthetisation of Gilbert Abbott, Dr. Warren's patient.

Morton's claim to the discovery was the subject of a deeply interesting monograph, "A History of the Gift of Painless Surgery," by E. Waldo Emerson, in 1896. He remarks: "The heat of the controversy has passed away and the claimants are gone. The evidence remains. It is to this . . . that the present generation should look in assigning the meed of gratitude and praise for this discovery." E. Waldo Emerson has made clear that any knowledge Morton had of anaesthesia was obtained from America's distinguished geologist and chemist Charles Thomas Jackson—a view I put forward in 1886. Those familiar with the history of the discovery need not be told that Jackson heard of C. W. Long's etherising patients, and visited him in Jeffersonville, Georgia, and solicited Dr. Long to acknowledge him as a fellow-worker in the discovery. This fact, which is well authenticated, was not known to E. Waldo Emerson, who accepted the dates given by Jackson for his experiments with ether.

Before settling down in Boston, Jackson made a tour of the principal European cities. He studied in London and Paris, conversed with men who had known Priestley, Beddoes, Davy, Cullen, Dalton, Lavoisier, and others. He knew of the inhalation of ether as a therapeutic agent, and learned to produce "fictitious airs." He lived in Paris when all France honoured and read Honoré de Balzac, and

"Ursule Mirout," in which the author gives such a vivid picture of the power of hypnotism, would undoubtedly excite an interest in the student for information on Esdaile's work in India; and all the more so as Velpeau was at that time operating on hypnotised patients.

When we recall to mind that these facts were common knowledge, it is unaccountable to find that in the "Address of Welcome" of the President of Massachusetts General Hospital on October 16th, 1896, the Gilbert Abbott operation is said to have been the first surgical operation under which the patient suffered no pain, no discomfort, no anxiety." And another speaker on the same occasion declared: Fifty years ago to-day occurred the first authentic, unquestionable, public exhibition of anæsthesia during a surgical operation." At best, Morton's claims to the discovery rest on an ignorance of the past; to the suggestion of ether by Jackson; and, most unhappily, to a greed of gain. The very name "letheon" stifles sympathy for his fate.

I am, Sir, yours truly,
 GEORGE FOY.

Dublin,
 January 13th, 1916.

SPECIAL CORRESPONDENCE.

FROM OUR OWN CORRESPONDENTS.

SCOTLAND.

COL. H. A. THOMSON, A.M.S.

AMONG the recipients of honours whose names appeared in the list recently published is Professor Alexis Thomson, at present acting as a Consulting Surgeon to the Expeditionary Force, who has been appointed Companion of the Order of St. Michael and St. George.

SANATORIUM TREATMENT AND MUNICIPAL ECONOMY.

A reply to the statements of the Edinburgh City Chamberlain as to the futility of expenditure on sanatorium treatment is contributed to the *Scotsman* of January 10th. Exception is taken to the statement that the cure of the individual and the eradication of the disease cannot be attained by sanatorium treatment. The contributor, who obviously supports the present system, goes over the familiar ground. If cases are got early, the results are good; if they are got later, they improve; if they do not improve, their pains are lightened. He urges that the Chamberlain's report depends on a misconception of the views of the Medical Officer of Health and of the Tuberculosis Officer, who, when they speak of housing and other antituberculosis measures, do not go further than to suggest that sanatorium treatment must be backed by other measures—"by the fearless exercise by a local authority of all its sanitary powers." The article then goes on to suggest that neither the housing crusade nor the sanatorium system can stand alone, and it enumerates the many other social factors to be considered—density of population, milk supply, temperance, etc., and finally argues that by giving up the present system the Corporation will spend £6,300 more, and get for its money 70 beds fewer, than at present. The contributor of the article states his case well, and his views will no doubt be thoroughly considered before any radical changes are made in anti-tuberculosis work in Edinburgh.

REGISTRATION IN THE MEDICAL SERVICE.

The Scottish Medical Service Emergency Com-

mittee urgently request those doctors who have not filled in their registration forms to do so without any further delay and to forward them to the secretary of the Committee at the Royal College of Physicians, Edinburgh.

GIFT FOR MEDICAL RESEARCH.

Sir Alexander M'Robert has given to Aberdeen University an endowment of about £750 per annum for a Georgina M'Robert Lectureship on Pathology, with special reference to malignant diseases.

The donor recently gave an endowment of £373 per annum to the Aberdeen Royal Infirmary. He is manager and director of the Cawnpore Woollen Mills Company, Ltd., but before going to India 30 years ago he was Neil Arnott, Lecturer in Experimental Physics at the Aberdeen Mechanics' Institution and Lecturer in Chemistry at Robert Gordon's College, Aberdeen.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, NOVEMBER 12TH, 1915.

The President, J. A. LINDSAY, M.D., F.R.C.P.,
 in the Chair.

SOME OBSERVATIONS UPON THE ELECTROCARDIOGRAPH, WITH NOTES OF CASES.

THE PRESIDENT read a paper upon the above. He said that amongst the recent advances in medicine an important place must be assigned to the development of instrumental methods of observation in connection with the heart in health and in disease. The polygraph and the electro-cardiograph had opened up a new chapter in this field, and had rendered many former observations more or less obsolete. While too much importance could not be assigned to a careful observation of the whole clinical complex, instrumental methods added new and important facts. By their agency the heart wrote its own message, and the cardiac script could be interpreted with increased precision as the work of observation and experiment went on. The phenomena of disease were thus presented at first-hand, and the duty of the clinician was that of interpretation. These methods were of special value in certain departments where the difficulties of diagnosis were formerly greatest, as, for example, in the differentiation of the cardiac arrhythmias, the detection of heart-block and of auricular fibrillation, and, in general, in the recognition of myocardial changes. The history of electro-cardiography was briefly summarised. The structure of the electro-cardiograph and the methods of employing the instrument were described, and the electrical phenomena of the normal heart explained. The chief applications of the instrument in disease were then dealt with, the following conditions being passed under review—viz., heart-block, auricular fibrillation, auricular flutter, myocardial degeneration, extrasystoles, and hypertrophy of the ventricles. In these various conditions the electro-cardiograph gave first-hand information, confirming a diagnosis which in some cases with the older methods of observation did not rise above a high degree of clinical probability. Electro-cardiography was probably destined to throw light upon the action of drugs, especially that of the cardiac remedies of the digitalis group. Electro-cardiography could not be expected to throw direct light upon valvular lesions. Its message was from the cardiac musculature, not from the cardiac valves. None of the usual valvular lesions had a precisely distinctive cardiogram, though that of mitral stenosis could sometimes be recognised. Hence, a normal electro-cardiogram was no guarantee of a normal heart.

But valvular lesions sooner or later produced muscle changes, and these wrote their story upon the cardiogram. The general question of the differentiation of the cardiac arrhythmias by mean of the electrocardiograph was discussed. In conclusion, the speaker deprecated any exclusive reliance upon instrumental methods. They were to be regarded as important adjuncts to the usual clinical procedures. The final test of cardiac sufficiency or insufficiency must remain the appeal to experience and to clinical observation. Science was, however, essentially measurement. Clinicians craved precision, and towards this end instrumental methods afforded an important contribution.

The paper was illustrated by numerous diagrams, tracings and a lantern demonstration.

Professor THOMPSON referred to the numerous difficulties in the employment and interpretation of the method, but expressed the belief that time would elucidate the majority of these. He pointed out that while the $p-r$ distance was important, the "t" wave was even more so, as showing whether ventricular contractions were dropped or not. The electrocardiograph was a clinical instrument, and it was noteworthy that its employment in the hospital in Belfast preceded the laboratory work. Every hospital would have to provide itself with the apparatus in the near future.

Dr. LITTLE, in adding his thanks, regretted that the meeting synchronised with one of the worst storms ever experienced in Dublin, which had, doubtless, prevented many, at least of the older members, from attending. His acquaintance with the instrument was confined to the literature of the subject, and as he deprecated the use of such complicated apparatus without full knowledge, he would refrain from a technical discussion.

The PRESIDENT, in reply, said that while the tracings shown were not entirely his own work, practically all had been obtained in the Victoria Hospital, Belfast. He was not a devotee of instrumental methods, which could never replace trained clinical observation, but they had one most important quality—namely, the elimination of the personal factor.

RECENT MEDICAL CLINICAL EXPERIENCES.

SIR JOHN MOORE read a paper on the above subject, which was printed in the MEDICAL PRESS AND CIRCULAR, December 22nd, 1915.

SPECIAL REPORTS.

ARMY MEDICAL HONOURS AND PROMOTIONS.

A SUPPLEMENT to the *London Gazette* issued on January 13th contains the following record of honours and awards for services in connection with the war:—

ORDER OF THE BATH.

The King has been graciously pleased to give orders for the following promotions in, and appointments to, the Most Honourable Order of the Bath, for services rendered in connection with military operations in the field:—

To be Additional Members of the Military Division of the Third Class, or Companions, of the said Most Honourable Order.—Surgeon-General Richard W. Ford, D.S.O., Col. Blenman B. Crayfoot, M.D., Indian Medical Service, Colonel James Maher, Army Medical Service, Colonel Michael J. Sexton, M.D., A.M.S., Colonel John J. Russell, M.B., A.M.S., Colonel Edward G. Browne, A.M.S., Lieutenant-Colonel (temp. Colonel) Walter C. Beevor, C.M.G., M.B. (retired pay), R.A.M.C., Major (temp. Colonel) Henry McL. Williamson Grav, M.B., F.R.C.S., R.A.M.C. (T.F.), Temporary Colonel Sir Bertrand E. Dawson, K.C.V.O., M.D., R.A.M.C. (T.F.). Australian Force: Colonel (temp. Surgeon-General) Michael W. Russell, Dep. Director-General, A.M.S., War Office.

SAINT MICHAEL AND SAINT GEORGE.

The King has been graciously pleased to give directions for the following promotions in, and

appointments to, the Most Distinguished Order of Saint Michael and Saint George, for services rendered in connection with military operations in the field:—

To be Additional Members of the Third Class, or Companions of the said Most Distinguished Order.—Colonel William W. Pike, D.S.O., F.R.C.S.I., Army Medical Service, Colonel Charles E. Nichol, D.S.O., M.B., A.M.S., Colonel Bruce M. Skinner, M.V.O., A.M.S., Lieutenant-Colonel and Bt. Col. Frederick Smith, D.S.O., R.A.M.C., Colonel George D. Hunter, D.S.O., A.M.S., Temporary Colonel John Atkins, M.B., F.R.C.S., A.M.S., Temporary Colonel William T. Lister, M.B., F.R.C.S., A.M.S., Colonel Charles A. Young, A.M.S., Colonel Stuart Macdonald, M.B., A.M.S., Colonel Gerald T. Rawnsley, A.M.S., Temporary Colonel Cuthbert S. Wallace, A.M.S., Temporary Colonel Henry Alexis Thomson, M.D., F.R.C.S., R.A.M.C. (T.F.), Lieutenant-Colonel Ransom Pickard, M.D., R.A.M.C. (T.F.), Lieutenant-Colonel Alfred Bertram Soltan, M.D., R.A.M.C. (T.F.), Lieutenant-Colonel John Archibald Hamilton, M.B., F.R.C.S., I.M.S., Lieutenant-Colonel Alexander Dunstan Sharp, R.A.M.C. (T.F.), Lieutenant-Colonel (temp. Colonel) Harry Alexander Hinge, R.A.M.C., Lieutenant-Colonel Alexander Milne-Thomson, R.A.M.C. (T.F.), Lieutenant-Colonel Winsmore Hooper, D.S.O., R.A.M.C., Lieutenant-Colonel George Abraham Moore, M.D., R.A.M.C., Lieutenant-Colonel James Robert McMunn, R.A.M.C., Lieutenant-Colonel Claude Kyd Morgan, M.B., R.A.M.C., Lieutenant-Colonel Frederick Kiddle, M.B., R.A.M.C., Lieutenant-Colonel William Henry Snyder Nickerson, V.C., M.B., R.A.M.C., Lieutenant-Colonel Frederick Septimus Penny, M.B., R.A.M.C., Lieutenant-Colonel Jonas William Leake, R.A.M.C., Lieutenant-Colonel Francis John Brakenridge, R.A.M.C., Lieutenant-Colonel Arthur Chopping, R.A.M.C., Lieutenant-Colonel Henry Edward Manning Douglas, V.C., D.S.O., R.A.M.C., Lieutenant-Colonel Langford Newman LLOYD, D.S.O., R.A.M.C., Temporary Hon. Lieutenant-Colonel Charles Gordon Watson, F.R.C.S., No. 1 British Red Cross Hos.; Major William Bertie Mackay, M.D., R.A.M.C. (T.F.), attached Northumberland Fusiliers (T.F.); Major Hamilton Maxwell Cruddas, I.M.S., Major William Riach, M.D., R.A.M.C., Major Percival Davidson, D.S.O., M.B., R.A.M.C.

Australian Force.—Lieutenant-Colonel Thomas Morgan Martin, Comm. No. 2 Australian General Hospital

Canadian Force.—Colonel Murray MacLaren, Canadian A.M.C., Lieutenant-Colonel George Gallie Nasmith, Canadian A.M.C., Lieutenant-Colonel Arthur Edward Ross, Canadian A.M.C., Lieutenant-Colonel William Henry Parkes, M.D., F.R.C.S., Comm. New Zealand Hospital.

MILITARY PROMOTIONS.

His Majesty the King has been further pleased to approve of the undermentioned rewards for valuable services rendered in connection with the war:—

To be Brevet-Colonels.—Lieut.-Colonel A. J. Macnab, F.R.C.S., I.M.S., Lieut.-Colonel J. M. Sloan, D.S.O., M.B., R.A.M.C.

To be Brevet Lieutenant-Colonels.—Major H. Boulton, M.B., I.M.S., Major G. Browse, M.D., I.M.S., Major F. G. Fitzgerald R.A.M.C., Captain M. G. Dill, M.D., R.A.M.C., Captain C. N. Draycott, R.A.M.C. (T.F.), Captain C. H. S. Frankau, M.B., F.R.C.S., R.A.M.C. (T.F.), Captain R. C. Ozanne, R.A.M.C. (S.R.), Captain R. G. H. Tate, M.D., R.A.M.C.

To be Honorary Captains.—M. Cohen, R.A.M.C. (T.F.), G. W. Harris, R.A.M.C. (T.F.), I. Keogh, R.A.M.C. (T.F.), J. H. Maunier, R.A.M.C. (T.F.), H. C. Okill, R.A.M.C. (T.F.).

COMPANIONS OF THE DISTINGUISHED SERVICE ORDER.

Major Ralph Bignell Ainsworth, R.A.M.C., Major Ernest Brabazon Booth, M.D., R.A.M.C., Major George Herbert James Brown, M.B., R.A.M.C., Major James Pearson Brown, M.B., R.A.M.C. (T.F.), Major Bernard Bruce Burke, R.A.M.C., Major James Hamilton Campbell, M.B., R.A.M.C., Major Patrick John Hanafin, R.A.M.C., Major Daniel Litton Hard-

ing, F.R.C.S.I., R.A.M.C., Major James Andrew Hartigan, M.B., R.A.M.C., Major Arthur Edmund Stewart Irvine, R.A.M.C., Major Nelson Low, R.A.M.C., Major Alban Anderson Meaden, R.A.M.C., Major Richard Arthur Needham, M.B., I.M.S., Major Michael Balfour Hutchison Ritchie, M.B., R.A.M.C., Major Frederick Emilius Roberts, R.A.M.C., Major William Francis Roe, R.A.M.C. (T.F.), Major James Samuel Yeaman Rogers, M.B., R.A.M.C. (T.F.), Major Eugene Ryan, R.A.M.C., Major Francis Cornelius Sampson, M.B., R.A.M.C., Major Arthur Briton Smallman, M.D., R.A.M.C., Major Richard James Campbell Thompson, R.A.M.C., Major Charles Harold Turner, R.A.M.C., Captain John Downie, M.B., R.A.M.C. (T.F.), Captain Joseph Wilfred Houston, M.B., R.A.M.C., Captain William Porter MacArthur, M.D., F.R.C.P.I., R.A.M.C., Captain Edward Michael O'Neill, M.B., R.A.M.C., Captain Frank Worthington, M.B., R.A.M.C., Temporary Lieutenant John Fraser Steven, M.B., R.A.M.C.

THE MILITARY CROSS.

Captain Jonas William Anderson, M.B., R.A.M.C. (T.F.), Captain David Charles Gordon Ballingall, M.B., R.A.M.C., Captain Henry Cuthbert Bazett, M.B., F.R.C.S., R.A.M.C. (S.R.), Captain Frederick Arnot Bearn, M.B., R.A.M.C. (S.R.), Captain Edward Charles Beddows, R.A.M.C., Temp. Captain Lancelot Gerard Bourdillon, R.A.M.C., Captain John Errol Moritz Boyd, R.A.M.C., Captain Noel Godfrey Chavasse, M.B., R.A.M.C. (T.F.), Captain Albert Geo. William Compton, R.A.M.C. (S.R.), Captain Harry Slater Cormack, M.B., F.R.C.S., I.M.S., Temp. Captain Robert Ewart Cree, M.B., R.A.M.C., Temp. Captain Claude Gordon Douglas, M.D., R.A.M.C., Captain John Cecil Alexander Dowse, M.B., R.A.M.C. (S.R.), Captain Philip Gordon Moss Elvery, R.A.M.C., Captain Roger Errington, M.B., R.A.M.C. (T.F.), Captain Eric Alfred Charles Fazan, R.A.M.C. (T.F.), Temp. Captain James Henry Fletcher, R.A.M.C., Temp. Captain William Foot, M.B., R.A.M.C., Captain Robert Forgan, M.B., R.A.M.C. (S.R.), Captain Archibald John Gilchrist, M.B., R.A.M.C. (S.R.), Captain Owen Hairsine, R.A.M.C. (S.R.), Captain Travis Hampson, M.B., R.A.M.C. (S.R.), Captain Frederick Duke Gwynne Howell, R.A.M.C., Temp. Captain Henry Rylands Knowles, M.B., R.A.M.C., Captain Stanley Dermott Large, R.A.M.C., Captain Hyman Lightstone, R.A.M.C. (T.F.), Captain (temp. Major) Edgar Rainey Ludlow-Hewitt, Royal Irish Rifles and R.F.C., Temp. Captain Eric Francis Wallace Meckenzie, M.B., R.A.M.C., Captain John MacMillan, M.B., R.A.M.C. (T.F.), Temp. Captain John Richardson Marrack, M.B., R.A.M.C., Captain William Hilgrove Leslie McCarthy, M.D., R.A.M.C., (S.R.), Captain Campbell MacQueen, R.A.M.C., Temp. Captain George Millar, M.B., R.A.M.C., Captain Sinclair Miller, M.B., R.A.M.C. (S.R.), Captain Thomas Mackinlay Miller, R.A.M.C. (S.R.), Captain John Murdoch, M.B., F.R.C.S., R.A.M.C. (T.F.), Temp. Captain George Ernest Neligan, M.B., F.R.C.S., R.A.M.C., Captain John Joseph O'Keefe, M.B., R.A.M.C., Captain William Calder Paton, M.B., I.M.S., Captain Gerard Petit, R.A.M.C., Temp. Captain Robert Cecil Robertson, M.B., R.A.M.C., Captain Henry Bowler Sherlock, R.A.M.C. (S.R.), Captain Sumner Hugh Smith, R.A.M.C., Captain Clifford William Sparks, R.A.M.C. (S.R.), Captain Owen William Dyne Steel, R.A.M.C. (T.F.), Captain Evelyn Alexander Sutton, R.A.M.C., Captain Fredk. Thomas Turner, R.A.M.C., Captain Quentin Vaughan Brooke Wallace, M.D., R.A.M.C. (S.R.), Temp. Captain John Richard Menzies Whigham, R.A.M.C., Captain Charles Albert Wood, M.B., I.M.S., Captain Thomas Wilson Wylie, M.B., R.A.M.C. (S.R.), Temp. Captain Robert Frew Young, M.B., R.A.M.C., Temp. Lieutenant Patrick Cagne, R.A.M.C., Temp. Lieutenant Harold Cane Godding, R.A.M.C., Temp. Lieutenant James Towers Kirkland, M.B., R.A.M.C., Temp. Lieutenant Richard Hugh McGillcuddy, R.A.M.C., Temp. Lieutenant Alfred Reginald Roche, R.A.M.C., Temporary Lieutenant Harold Arthur Rowell, R.A.M.C., Temp. Lieutenant Algernon

Charles Stanley Smith, R.A.M.C., Temp. Lieutenant William Norman Watson, M.B., R.A.M.C., Temp. Lieutenant Archibald Francis Wright, M.B., R.A.M.C.

Australian Force.—Captain Joseph Espie Dods, Aus. A.M.C.

New Zealand Force.—Captain Robert Neil Guthrie, New Zealand A.M.C.

OBITUARY.

DR. T. W. BUTCHER, BLACKPOOL.

DR. T. W. BUTCHER, Blackpool, died at his residence on January 10th. Deceased, who was 49 years of age, was for some years police surgeon, and had taken an active part in various movements in the town. He was hon. surgeon to the Foxton Dispensary, president of the Blackpool Microscopical Society, and a former hon. secretary of the local Literary and Scientific Society. He was out of doors up to a few days before his death, but for some time had suffered from diabetes.

MEDICAL NEWS IN BRIEF.

Hospital Saturday Fund.

ACCOUNTS of the Hospital Saturday Fund (London) for 1915 were closed on the 10th inst. Notwithstanding the many appeals in connection with the war made to the public during the year, the income of the fund steadily progressed, with the result that the total reached £36,790 as compared with £30,130 for the previous year. Between December 28, 1915, and January 10, 1916, inclusive, the sum of £11,406 was forwarded to the head office.

The following figures show the fluctuations in contributions received and the benefits granted during the last three years:—

Contributions received—

	1913.	1914.	1915.
General fund	£30,375	£30,130	£36,790
Distribution committee	8,244	8,701	7,899
Surgical appliance committee	1,728	1,743	1,961
Ambulance committee...	56	102	88
Totals	£40,403	£40,676	£46,738

Benefits granted 55,264 52,334 46,472

The splendid manner in which the Metropolitan hospitals have succoured our sick and wounded soldiers has touched the hearts and stirred the wills of all sections of the community, as evidenced by the remarkable increase in the incomes of the three large Metropolitan Hospital Funds for 1915.

Duchess and Red Cross Work.

THE Duchess of Connaught has accepted the Presidency of the Canadian Red Cross Association.

Health of the Troops.

MR. TENNANT referring to sickness and mortality among troops in the Salisbury Plain district, states that the annual ratios per 1,000 are, during the period September 1st to December 31st:—Admissions, 325.4; deaths, 1.88. Both these ratios are lower than those for peace time.

Medical Practitioners and the R.A.M.C.

It is officially announced that the Army Council consider that no qualified medical practitioner who is willing to accept (if offered) a commission in the Royal Army Medical Corps should be accepted as an ordinary combatant. It is understood that the Central Medical War Committee will circularise the profession, stating that any medical practitioner who has enlisted under the group system should immediately enrol himself under the Committee's

scheme as willing to accept a commission in the Royal Army Medical Corps if offered him. To every practitioner who enrolls the Committee issues a certificate of enrolment. Every medical practitioner who has attested and enrolled under the Central Medical War Committee's scheme should, when called up, produce to the recruiting officer his certificate of enrolment. He will then not be posted to a combatant unit, and will await instructions from the Central Medical War Committee.

New Hospital for Nervous Diseases.

A NEW military hospital for neurasthenic soldiers will be ready for occupation at the end of this month. It almost directly faces King's College (the Fourth London General Hospital), and has been taken over by the War Office from the London County Council. The Maudsley Hospital, as it is known, was built out of money left to found an institution for mental cases which were not suitable for asylum treatment. It is equipped on up-to-date lines, and, though it was originally planned to contain only 100 beds, the military authorities are providing equipment for 150, which will allow the treatment of about 600 patients a year. The hospital communicates directly with Grove Lane London County Council Schools, an annexe of King's College, now used also for patients suffering from neurasthenia.

Germany's Decreasing Births.

At a recent meeting in Berlin of the society for the study of the population statistics, with the object of preventing the alarming decrease in the birth rate, Professor Wolff announced that the Russian people are increasing annually by from three to four millions, whereas the increase in Germany is only 800,000 per annum. It was therefore held to be of the greatest importance to find means by which to add to the population. The *Süddeutsche Monatshefte* strongly supporting this view says that 200 million Germans will be required to defend the Empire in the year 2000.

General Seely's Gift.

BROOKE HILL, Isle of Wight, the fine new residence built by the late Sir Charles Seely, has been placed at the disposal of the Royal Flying Corps by Brigadier-General J. E. B. Seely, M.P., to be used as an officers' convalescent home. It will be opened almost immediately.

Public Health Training.

COURSES of training for men and women for work in the public health service of the country have been arranged by the Royal Sanitary Institute, Buckingham Palace Road. The course for sanitary inspectors, which is open to women as well as men, begins on February 7th, and the course for health visitors on February 21st.

Serum at Fire Stations.

THE District Council of Edmonton proposes to use the fire brigade for public health work. The suggestion is to keep supplies of serum at the brigade station, so that when doctors are called to cases of diphtheria they can provide anti-toxin treatment without delay.

Curative Baths at Bournemouth.

At the last meeting of the Bournemouth Town Council a letter from the Bournemouth Medical Society was read to the Health Committee, stating that the society had come to the decision that every effort should be made to promote Bournemouth as a definite health resort in order to compete as far as possible with other health resorts in this country in taking the place of those Continental spas and health resorts which, in consequence of the war, would be avoided by the people of this country. For this purpose the society had appealed to the medical practitioners of Bournemouth, Poole and Christchurch inviting them to join a general committee, and they

asked the Council that such committee should be recognised by them as an advisory medical committee by whom suggestions could be made and to whom the Council could at any time apply for advice in all matters connected with the best means of furthering the object named. The Town Clerk was instructed to reply that the Council would be very pleased to co-operate with the proposed new committee in the direction indicated.

Relief for Hospitals.

In the House of Commons on January 11th Sir P. Magnus asked the Chancellor of the Exchequer what steps he had taken to give effect to his promise to remove the duty on alcohol used for medical or surgical purposes in hospitals.

Mr. McKenna, in reply, stated that it was proposed that the relief should take the form of grants from public funds. A committee had been appointed to advise as to the basis of such grants.

National Memorial Hospital at Newport.

THE offer of Sir A. Garrod Thomas's house at Newport, Monmouth, for the purpose of a hospital for children suffering from tuberculosis was accepted at a conference of the medical side of the Welsh National Memorial Association at Cardiff. It was decided also to recommend that the gift of £1,000 by Messrs. Griffiths, of Newport and Cardiff, for fitting up the house, be accepted and the work proceeded with.

St. Bartholomew's Memorial Service.

THE memorial service held on January 13th for those members of the medical staff of St. Bartholomew's Hospital who have fallen in the war was attended by Lord Sandhurst, treasurer of the hospital and Lord Chamberlain to the King, who represented His Majesty; the medical staff, including Sir Lauder Brunton, and relatives of the dead.

Numbers of the Medical Profession.

We have received from the President of the General Medical Council the following statement regarding the number of medical practitioners and medical students registered in 1915:—

Medical Practitioners Registered.

	In 1915.	Annual average during the five years 1910-1914.
England	863*	591
Scotland	412	384
Ireland	251	197
Total	1,526	1,172

* This number includes 269 practitioners with Colonial and foreign qualifications.

Medical Students Registered.

	In 1915.	Annual average during the five years 1910-1914.
England	754	620
Scotland	694	517
Ireland	470	304
Total	1,918	1,441

Antityphoid Inoculation in the Army.

ASKED whether it was intended to inoculate with antityphoid serum all or any men who might be compulsorily attested under the operation of the Military Service (No. 2) Bill, Mr. Tennant replied that he thought the men in question would be in the same position as men who undertake voluntary enlistment.

Poor Law Military Hospital Nurses.

OWING to protests from many Poor Law authorities, the War Office has cancelled its order restricting the pay of nurses in Poor Law war hospitals.

The War Office ordered that probationer nurses in war hospitals established in Poor Law buildings should be restricted to the rates of pay they were

receiving before the conversion of such buildings to military use.

The consequence of this was that the nurses were paid much less than those employed in other military hospitals.

The War Office has now cancelled the order as to the restriction of pay, and consequently nurses employed in Poor Law military hospitals will be permitted to receive the same rates of pay as prevail elsewhere.

Military Service of Medical Students.

THE President of the General Medical Council has received from the War Office the following intimations relating to medical students :—

I. Students who at or before the close of the present winter session will be qualified for entry to one of the examinations for third-year students in medicine, and duly enter for the examination for which they are studying, will not be attested until after its conclusion; and if they are successful will be included in the class of fourth-year students (under Lord Derby's scheme).

II. Directions have been sent to all commands in England and Scotland, instructing them to inform military representatives [on recruiting tribunals] that in cases where students, attested in Army Reserve, Section B, appeal for their calling-up to be postponed until after they have taken an examination, this request may be granted provided the examination will be held before March 31st, 1916.

The President will be grateful if steps are taken by the authorities of each medical school to call attention to these official intimations, which have special reference to students of the first, second and third years of the professional course.

Conjoint Examinations in Ireland.

THE following candidates have passed the 1915 examination by the Royal College of Physicians and the Royal College of Surgeons :—

Preliminary Examination.—Isaac W. Arnovitch, Lucretia H. H. Byrne, Anthony B. Clery, William E. Colahan, Robert M. Corbet, John J. Clune, Thomas E. Donovan, Anthony B. Doyle, Thomas C. Doyle, Anthony C. Esmonde, M. W. Fraser, Roberta E. Fisher, William A. Graham, Sidney G. Gilmore, Thomas M. Goldon, Thomas Heffernan, John Hewitt, Margaret Holliday, Patrick Killeen, J. J. A. Lord-Flood, Thomas J. McCormack, Alexander McLean, Henry T. Macaulay, Abraham Martinson, Patrick Moylan, Robert J. Ogden, Patrick J. A. O'Connor, Thomas L. Quinn, Joseph Rubenstein, George E. Strahan, John Sheil, Richard T. Taylor, Mary E. Tempest, John W. Tighe, H. E. W. Watts Waters.

Second Professional Examination.—Miss H. G. Rea (with honours), S. H. Berwitz, J. P. Brennan, J. A. Cunningham, P. J. Filose, S. A. Gailey, Miss E. Gleeson, W. J. McElhinney, P. J. McGing, C. Murray, M. C. Myerson, J. C. Rutherford, R. T. Stoney.

Third Professional Examination.—Miss E. Budd, D. L. Crowe, I. B. Culhane, F. Daly, E. H. H. Lloyd-Dodd, J. P. Doyle, P. J. Flood, H. Hurst, D. C. Kelleher, J. E. Lucas, T. P. McDonald, E. T. McFilligott, M. F. Murphy, M. M. Price, G. W. Pope, G. C. F. Roe.

Supplemental Final Examination.—Jack Cohen, John Dwyer, Thomas Farrell, Owen J. M. Kerrigan, John F. Saunders Magner, Thomas J. Ryan, John J. Walshe, Patrick W. Walshe.

Final Examination.—Michael Burke, Lawrence L. Davys, Maurice de Caestecker, John A. Fretton, Daniel L. Kelly, Thomas F. Moran, Vincent A. Power, James Ryan, Cecil W. C. Robinson.

The Royal College of Surgeons in Ireland.

THE following candidates have passed :—

First Dental Examination.—Michael J. Bannigan, Peter P. Hogan, Matthew J. Hunt, Charles A. McGlade, Stephen J. Morrough, Richard Walters.

Final Dental Examination.—Peter E. F. Dunn,

George V. Hartigan, Charles S. Hillis, Montague R. Mosbery, John F. O'Sullivan, James P. Timony, Patrick J. Slattery.

Primary Fellowship Examination.—William E. Cooke, Sylvester J. Healy.

Final Fellowship Examination.—Lieut. Thomas Dowzer, R.A.M.C., Capt. John G. J. Green, R.A.M.C. Licence in Surgery Examination.—Myles Keogh.

Society of Apothecaries of London.

THE following candidates having passed the necessary examinations in December, were granted the L.S.A. Diploma of the Society, entitling them to practise Medicine, Surgery and Midwifery :—A. Z. Abushady, R. N. Craig, W. Fox, I. H. Pearse, and E. E. Samaraweera.

MEDICAL WAR ITEMS.

CAPT. CYRIL ARMAND BERNARD, Royal Army Medical Corps, attached to 4th York and Lancaster Regiment (T.F.), wounded in the North of France, practised, before going on active service, in Rodney Street, Liverpool, and is an L.R.C.P. and L.R.C.S. Edin.

LIEUTENANT M. A. SWAN, R.A.M.C., attached R.F.A., who has been wounded, graduated M.B., Ch.B., in Edinburgh, in 1903, after which he was house surgeon and physician at Paisley Infirmary. Prior to joining the R.A.M.C. last February he was in practice in South Shields.

LIEUTENANT WILLIAM WILKIE DEANS, Royal Army Medical Corps, who died of wounds received whilst serving with the Mediterranean Force, was an L.R.C.P. and L.R.C.S. of Edinburgh, and also since 1901 a Licentiate of the Royal Faculty of Physicians and Surgeons, Glasgow.

Capt. William Ernest Rielly, Royal Army Medical Corps, who died whilst serving at the Dardanelles, was attached to the 3rd City of London Regiment. He resided at Barnes, and was formerly House Physician at the Brompton Consumption Hospital. Captain Rielly obtained the joint M.R.C.S. and L.R.C.P. Lond. qualifications in 1891, and three years later took the M.B. degree at Durham and the Diploma in Public Health at Cambridge.

SURGEON CHARLES FRANK SCHULER, R.N., Hawke Battalion, who has been wounded at the Dardanelles, was in practice at West Norwood before volunteering for active service with the Navy. Educated at St. Thomas's Medical School, he was formerly Clinical Assistant to the children's department and House Surgeon at St. Thomas's Hospital, and House Physician to the Evelina Hospital for Children. He became M.R.C.S. and L.R.C.P. Lond. in 1910.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

NOTES CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 2s.; post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

"SPOONERISMS."

ACCORDING to the "Gazette" of the 3rd General Hospital, there has lately been an astonishing revival of "spoonerisms." It quotes a doctor who began by calling his audience tons

of soil, next informed them that the first thing they must learn was to shout and scot, and wound up by promising his hearers that on their return in triumph all the hags would be flung out to welcome them.

SOLON (Clifton).—The report of the Medical Officer of Health for Bristol shows that during the week ending January 8th, 151 births and 100 deaths were registered, corresponding to annual birth and death rates of 21.6 and 14.3 respectively. The death rate for the corresponding week of last year was 29.2, and the ten years' average was 16.1.

BANDON (Salisbury).—We do not favour an immediate inquiry.

CARPENTER AND JOINER.

A DOCTOR, giving evidence at Clerkenwell county court, said that in his younger days he was apprenticed as a carpenter. The correspondent who sends us this cutting states that the medico still executes repairs, of a professional kind.

REBOUND (Leith).—In last week's issue we gave prominence to the gentleman's utterance.

A DR. GRACE BAT.

A CRICKET bat autographed by Dr. W. G. Grace and used by him in 1912 was sold three times in one day at a sale for the Red Cross and the Allies' Agricultural Relief Fund held in Montreal Park (the seat of Lord Amherst), realising £35 14s.

LOTUS (Sandown).—Sinapis has referred to the subject on more than one occasion.

FELIX (Bath).—It is estimated that more than 2,000,000 women and girls have come into the labour market since the beginning of the war.

THE LATEST RECRUITING POSTER.

A GOOD remedy to stop your hat from blowing off on windy days is to wear a khaki cap.

PAGODA (York).—Queen Alexandra has given £25, her annual subscription, to the Chelsea Hospital for Women.

WASTAGE IN THE ARMY.

MR. TENNANT states that the wastage in the infantry is estimated by the military authorities at 15 per cent. per month.

A LANCE-CORPORAL of the Buffs, who had lain dumb in hospital in Boulogne for six weeks, recovered his power of speech on being visited unexpectedly by his mother.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 19TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF THE HISTORY OF MEDICINE) (1 Wimpole Street, W.).—5 p.m.: Dr. Arnold Chaplin: Mortality in the British Army 100 Years Ago. Dr. H. Selve Bennett: Joshua Ward. Books, MSS., etc., are on view at 4.30 p.m.

THURSDAY, JANUARY 20TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF DERMATOLOGY) (1 Wimpole Street, W.).—5 p.m.: Mr. J. E. R. McDonagh and Dr. H. Spence: Cases of Syphilis treated by "Intramine." Dr. Parkes Weber: Kaposi's so-called "Idiopathic Multiple Pigment Sarcoma"—a Case described in 1905, showing Improvement. Dr. J. H. Sequeira: Scleroderma with Graves's Disease. Exhibition of Cases (at 4.30 p.m.).

ROYAL SOCIETY OF MEDICINE (SECTION OF BALNEOLOGY AND CLIMATOLOGY) (1 Wimpole Street, W.).—5.30 p.m.: Paper: Dr. J. Campbell McClure: Hydrological Treatment of Gastro-intestinal Stasis. (At 7 p.m. the members will dine together at Pagani's Restaurant, Great Portland Street, W., and members may bring guests. Members who wish to dine are requested to send their names to Dr. J. Campbell McClure, 59 Harley Street, W.)

CENTRAL MIDWIVES BOARD (Caxton House, Westminster).—Meeting.

FRIDAY, JANUARY 21ST.

ROYAL SOCIETY OF MEDICINE (SECTION OF ELECTRO-THERAPEUTICS) (1 Wimpole Street, W.).—8.30 p.m.: Demonstration: Sir James Mackenzie Davidson will demonstrate a "Commutator Break" for Utilising the Current at "Make" as well as the Current at "Break." Paper: Dr. E. P. Cumberbatch: The Use of the "Simpson Light," with a Description of the Apparatus. Dr. Russ will give an Account of the Physical Properties of the Light. The Apparatus for the production of the Light will be shown. A Lethalising Couch designed by Sir James Mackenzie Davidson will be on view.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE (11 Chandos Street, Cavendish Square, W.).—5.30 p.m.: Paper: Dr. W. J. Penfold: The Etiology of Typhus.

CENTRAL MIDWIVES BOARD (Caxton House, Westminster).—11 a.m.: A Special (penal) Meeting.

MONDAY, JANUARY 24TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Discussion on Gunshot Wounds of the Chest (introduced by Colonel Sir J. R. Bradford, A.M.S., Captain H. Henry, R.A.M.C., and Captain M. Davies, R.A.M.C. (T.). Lieutenant-Colonel W. H. White, R.A.M.C. (T.), Dr. S. West, Dr. M. Leslie, and others will take part in the discussion.

THE ROYAL SOCIETY OF MEDICINE (SECTION OF ODONTOLOGY), 8 p.m.: Paper:—Mr. W. Courtney Lyne (communicated by Mr. Montagu F. Hopson): The Significance of the Radiographs of the Pitted Teeth. Professor Arthur Keith, Professor A. S. Underwood and Dr. Smith Woodward will take part in the discussion. Casual Communication:—Mr. Rushton: Total Absence from Deciduous and Permanent Dentition.

TUESDAY, JANUARY 25TH.

THE ROYAL SOCIETY OF MEDICINE (SECTION OF PSYCHIATRY), 8.30 p.m.: War Discussion:—A special discussion on The Functional Neuroses without Visible Sign of Injury caused by Shell Fire, will be opened by Dr. Mott, F.R.S., and will be adjourned to the meeting of neurology on Thursday, January 27th. N.B.—Members of other Sections interested in the subject are specially invited to be present.

Vacancies.

Birkenhead Borough Hospital.—Junior House Surgeon. Salary £180 per annum, with board and laundry. Applications to the Secretary.

Bridgwater Hospital.—House Surgeon. Salary £125 per annum, with board, lodging, and washing. Applications to the Honorary Secretary, Edward Trevor, Bank Chambers, Bridgwater.

Bury Infirmary.—Senior House Surgeon. Salary £250 per annum, with board, residence, and washing. Applications to the Honorary Secretary, Infirmary, Bury, Lancs.

Chesterfield and North Derbyshire Hospital.—Second House Surgeon. Salary £150 per annum, with board, apartments, and laundry. Applications to the Secretary.

County Asylum, Chester.—Junior Assistant Medical Officer. Salary £200 per annum, together with a war bonus of £50, with board, lodging and washing. Applications to G. Hamilton Grills, M.D., Medical Superintendent.

Derbyshire Royal Infirmary, Derby.—House Physician and Casualty Officer. Salary £200 per annum, with board, residence, etc. Applications to E. Forster, Secretary.

Hulme Dispensary, Dale Street, Streteford Road, Manchester.—House Surgeon. Salary £250 per annum, with apartments, attendance, coal, and gas. Applications to Honorary Medical Secretary.

New Hospital for Women, Euston Road, N.W.—Pathologist. Salary £125 per annum. Applications to the Secretary.

North Ormesby Hospital, Middlesbrough.—House Surgeon. Salary £150 per annum, with board, residence and laundry. Applications to Arthur Williams, Secretary.

Parish of Dunrossness.—Medical Officer and Vaccinator. Particulars of the appointment to be had from the subscriber. Applications to G. W. Jamieson, Clerk, Cummingsburgh, Shetland.

The Victoria Hospital for Children, Tite Street, Chelsea, S.W.—Senior Resident Medical Officer. Salary £250 per annum, with board, lodging, and washing. Applications to the Secretary.

Warneford General Hospital, Leamington Spa.—Resident Medical Officer. Salary £150 per annum, with residence, etc. Applications to Fred Smith, House Governor.

Appointments.

GRAVES, A. J., M.R.C.S., L.R.C.P., Certifying Factory Surgeon for the Cleator District, co. Cumberland.

GROVES, T. C., M.B., B.S.Lond., Medical Superintendent of the Hereford County and City Asylum, vice Dr. Morrison, deceased.

PEACHELL, G. E., M.B., B.S.Lond., Medical Superintendent of the Dorset County Asylum, Dorchester.

WEBBER, W. W., L.R.C.P.Edin., M.R.C.S., Certifying Factory Surgeon for the Crewkerne District, co. Somerset.

Births.

LAIRD.—On January 10th, at Peshawar, India, the wife of Captain W. Balfour Laird, Staff Surgeon, R.A.M.C., of a daughter.

MACKINNON.—On January 9th, at Nairobi, British East Africa, the wife of Murdoch Mackinnon, M.D., D.P.H., of a daughter.

PENNY.—On January 7th, to the wife of Captain C. H. Greville Penny, R.A.M.C., at Grenfell, Green Island—a daughter.

REYNOLDS.—On January 3rd, at Shameen, Canton, China, the wife of W. Graham Reynolds, M.R.C.S., L.R.C.P.—a son.

TROUP.—On January 9th, at Hawkwell Place, Pembury, the wife of Captain W. Annandale Troup, M.B., R.A.M.C., of a son.

WALKER.—On January 10th, at the Red House, Uxbridge, to Dr. and Mrs. Walker—a son.

Marriages.

BARFETT—HANCOCK.—On January 11th, at Christ Church, Sarbiton, Rev. J. C. F. Barfett, Vicar of Halesdown, Cornwall, to Mary Deborah Hancock, M.A. (T.C.D.), L.R.C.S.Edin., L.F.P.S.Glasgow, daughter of Mr. and Mrs. E. H. Hancock, Altrinton, Surbiton.

GRIFFITH—GULSTON.—On January 11th, at Adel, Leeds, by the Rev. W. H. Draper, Lieut. David W. Griffith, R.A.M.C. (T.F.), of Raglan, Mon., to Grace, eldest daughter of F. W. K. Gulston, of Kuling, China.

SINCLAIR—SOUTER.—On January 8th, at Forres, N.B. Neil Frederick Sinclair, M.R.C.S., L.R.C.P., eldest son of Dr. and Mrs. Sinclair, Jamaica, to Chrissie Stewart, second daughter of Mr. and Mrs. J. F. Souter, Roseville, Forres.

Deaths.

BALE.—On January 12th, at Heathbank, Stockport, William Barker Bale, M.R.C.S., L.R.C.P., second son of the late William Bale, J.P., M.R.C.S., L.R.C.P., of Heaton Norris, aged 49 years.

BOAM.—On January 10th, at his residence, 77 Great Brook Street, Birmingham, Herbert Boam, M.R.C.S.Eng., L.R.C.P.Lond.

WILLIAMS.—On Sunday, January 16th, at his residence, William Street, Greenwich, Herbert Williams, M.D.Lond., D.P.H.Camb., Port Sanitary Officer for London. Aged 53.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, JANUARY 26, 1916.

No. 4.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

FROM the vehemence of the official protestations to the effect that the Kaiser has been suffering merely from a harmless furunculosis, it is to be supposed that something really is wrong. I have heard it said that the affection of the larynx was tuberculosis and not cancer; but it is obvious that this is a mere guess. What is certain is that William II. would have fulfilled his promise to read the speech from the throne had he not been medically prevented from so doing; it is also certain that a furunculosis would not have been a sufficient reason for such a prohibition, and that an affection of the larynx would. Moreover, the walks in the garden and the excursions "to the front," which have been so much insisted upon, are quite as much in keeping with tubercle or carcinoma as they are with furunculosis. In the case of either cancer or tubercle the prognosis is necessarily grave. At his age and with his heredity, cancer is by far the more likely of the two, but tubercle is by no means unlikely.

THE popular saying that a green Yule-tide makes a full churchyard has, owing to the mild weather we have enjoyed, been much quoted recently. Such scientific support as may be given to the saying arises from the fact that frost is a germ destroyer. This factor is, however, probably more than counterbalanced by the opportunity given to germs by the hermetically sealed windows which hard weather brings in its train. Extremes of temperature are very trying to old people and delicate children. This is common knowledge of which ample confirmation may be found in the obituary columns during a spell of really cold weather. The old-fashioned Christmas weather may be very artistic; for the vigorous it is very agreeable, especially in the country; but for the old and feeble it not infrequently supplies the final straw.

ONE looks to the "Strand Magazine" for various delights—was it not from those pages that Sherlock Holmes thrilled and enthralled a whole generation?—but I have not hitherto thought of it as a medical contemporary. And yet

the current number forces me so to regard it. Dr. Edwin F. Bowers has contributed to this number an article on the subject of Zone-Therapy, which is the name given to a method of relieving and providing against pain, discovered and practised by Dr. William H. Fitzgerald, of Hartford, Connecticut. The name given to the article, "Squeeze Your Toe and Stop the Toothache," is characteristically Yankee, but unless the substance is much more than usually Yankee and yellow, it is well worthy of the attention of broad-minded men. Dr. Fitzgerald, it seems, occupies a position in his own country which commands respect. He is a graduate of the University of Vermont; he was for two years clinical assistant at the Central London Ear, Throat and Nose Hospital, and for another two years he acted as assistant to Professor Politzer in Vienna. He is now the senior surgeon to the Throat and Nose Department of St. Francis Hospital in Hartford.

Pressure as Analgesic. "ACCIDENT disclosed that pressure on a certain spot in the nostril gave practically the same result as the use of cocaine. That was six years ago.

He began experimenting, and he found there were many spots in the nose, mouth, throat and on the tongue which, when pressed firmly, deadened certain areas to all sensation. He began using nerve-pressure instead of local anaesthetics in his operations, and now he rarely has any use for cocaine." There is nothing in this which makes any undue claims upon our credulity; it may indeed be said to coincide with much that is already known on the subject. It is the subsequent development which, to many of us, must, to use another Yankee expression, appear rather "tall."

Zones. THE body is divided by Dr. Fitzgerald into ten more or less perpendicular zones, which zones correspond to the fingers or the toes on the same side of the body. Successfully to employ the method you must know your zones; which finger or toe to press, and whether that finger or toe is to be pressed antero-posteriorly or laterally. "If the first joint of the thumb is pressed firmly and steadily for three minutes it will relieve and favourably influence

pain in the stomach, the chest, the front teeth, the nose, the great toe, as well as everything else in this zone. But it will have not the slightest influence upon the tonsils, the liver, or the spleen, for they are in the fourth zone, and to affect them it is necessary to make pressure upon the fourth finger. Furthermore, pressure on the right hand will not have any effect on the left half of the body."

Zones and Dentistry. DENTISTS are said to be less hide-bound than physicians, and while the latter have been engaged in scoffing at Dr. Fitzgerald the former have been giving his methods a trial.

Herein the dentists are obviously right; for even if the methods do no good, they are obviously innocent of harm. "Many dental operators prefer to make pressure with thumb and finger over the root of the tooth operated upon. If this seems ridiculous to you, try it some time when you have an aching tooth. Start gently, increasing the pressure, and holding steadily for three minutes. Maybe your thumb and finger will ache more than the tooth. If the nerve is not exposed and there is no abscess at the root of the tooth, this pressure will stop the aching every time." Unless the whole article is an audacious piece of de Rougemontism, which it does not seem to be, the matter is well worthy of careful attention and serious investigation.

Dr. Guy Hinsdale. THE many friends in this country of Dr. Guy Hinsdale, of Hot Springs, Virginia (he is a Fellow of the Royal Society of Medicine), will be pleased to see that he has shared with Dr.

Adolphus Knopf, of New York City, the prize of 1,500 dollars offered by the Smithsonian Institution for the best treatise on "The Relation of Atmospheric Air to Tuberculosis." Dr. Hinsdale's treatise, which runs to 136 pages, is a most exhaustive, painstaking and scholarly production. It is published in Vol. XXX (1914) of the Transactions of the American Climatological and Clinical Association. The object of the Association is the clinical study of disease, especially of the respiratory and circulatory organs and of climatology and hydrology; certainly no more masterly contribution to the whole field of these studies could be produced than this well-written, well-illustrated, and scientifically-conceived treatise of Dr. Hinsdale's. It is a work which no one who is interested in the latter-day treatment of tuberculosis can afford to be without.

Science and Education. WRITING to the *Times* a short time ago, Sir Ray Lankester deplored the neglect of science in our system of education. As a contribution to this question, Dr. C. A. Mercier wrote a letter, which appeared on the 17th inst., in which he says:—"One subject that Sir Ray Lankester relegates to an insignificant position I should place in the forefront of education. I refer to the knowledge and use of the mother tongue. Clear thinking cannot be attained without accuracy in the use of language—of language as an instrument of thinking and a means of expression; and exercise in clearness and

accuracy of expression is itself exercise in clearness and accuracy of thinking. The neglect of this subject in our system of education is gross and unpardonable, and its disastrous effects are seen everywhere. Parliamentary draughtsmen, who should be the experts of experts in the matter, are a byword of incompetency. Politicians and philosophers are obscure of set purpose, but so low is the standard of clearness of expression that their utterances are allowed to pass without exposure. Writers and speakers of every class vie with one another in the use of language that is obscure, confused, ambiguous, and illogical, besides being often unidiomatic and un-English. It is not for its want of grace and elegance that I deprecate this practice; it is because the confusion and obscurity of the language faithfully reflect the confusion and obscurity of the thought."

Clearness and Elegance. THIS is a question on which anyone who has had anything to do with editing a paper, and—must I say it?—especially a medical paper, will cordially endorse Dr. Mercier's

strictures. The standard of clearness of expression in medical literature is deplorably low; and in saying this I am, with Dr. Mercier, distinguishing between clearness and elegance. Clearness is a duty which few take the trouble to perform; it can be, and ought to be, acquired by everyone who has anything to say which is worth saying. Elegance is a gift which is not possessed by many writers, lay or medical. With the exception of Dr. Mercier himself, Mr. Stephen Paget, Sir Clifford Allbutt, Sir William Osler, and Dr. Leonard Guthrie, the ranks of the profession cannot be said to hold more than one or two in whom literary grace is at all conspicuous. I first made Dr. Mercier's acquaintance as an author when about ten years ago I first read his article on "Vice, Crime and Insanity" in the 1st edition of "Allbutt's System of Medicine," Vol. VIII., which I have ever since regarded as a model of what such writing should be.

The late Lord Salisbury. It is many years since I heard the late Lord Salisbury, who was himself an exponent of elegance, both in the spoken word and the written, oppose the abolition of English as a subject in the competitive examinations for Sandhurst. I do not now recall the reasons which were advanced for the abolition which was proposed, and, despite Lord Salisbury's opposition, ultimately carried, but I well remember the picture which "the master of flouts and gibes and sneers," as Disraeli called him, drew of the probable results of the measure. One was that it would lower the standard of English not only among cadets, but in all classes of the educated community, because the subjects demanded by the Civil Service Commissioners would be cultivated in the schools and those not demanded would be neglected. To judge by the standard of English in current medical literature, this forecast has been abundantly justified in the event.

It is said that the same famous statesman was fond of advising people, sometimes very emphatically, to mind their own business. If this advice were more frequently acted

A Busy-Scottie-Body. upon, doctors would be spared a great deal of the irritation provoked by the unwarrantable interference of laymen, and especially of laywomen, in matters purely professional. A good example of the kind of busy-bodyism to which we are so often subjected by effusive hearts and muddle-heads was afforded by the action which Dr. J. G. Wallace-James, of Haddington, brought against Mrs. Georgina Fergusson or Baird, of Coulston, Haddington, for an alleged slander contained in a letter written by the lady to the Chairman of the Haddington Parish Council, representing that Dr. Wallace-James had been guilty of gross and wilful failure of professional duty in omitting to procure the services of the district nurse to a patient. The *Glasgow Herald* reports that "his Lordship considered that the lady was not warranted, without making further inquiry, to jump to the conclusion that the patient was entitled to the doctor's services in his capacity as medical officer. Her motive, as it appeared to his Lordship, was of the best. Her sole concern was for the welfare of the sick poor. She had no desire whatever to injure the pursuer's personal reputation, and so far as his Lordship could judge, she believed she had adequate information on which to base her charge. But she had not." Could there possibly be a better example of the truth of the saying that more harm is done by want of head than want of heart?

Recruiting Again. FROM a letter which appeared in *The Times* on January 18th, signed "Surgeon" (I wish he had signed his name), it is evident that the evils which I have so often referred to in

connection with enrolling the unfit are to be very much intensified under the order which has recently been issued. "Within the last few days the instructions have been altered, and the procedure now authorised is as follows:—Every recruit is first to be seen and the oath of allegiance administered by the recruiting officer, who decides whether he shall be medically examined or not, and if examined, whether found fit or not by the medical officers, he is to be paid his 2s. 9d. and receive an armlet. The result is that, although the new regulations have been in operation but a few days, in one recruiting office, with only a moderate number of applicants for enlistment, several cases of feeble intellect, epilepsy, stiff joints, and other conditions rendering them absolutely useless in the Army have been sworn in as soldiers and received their money and armlet. Such men must, necessarily, be a source of ridicule or pity to their friends and relations who know their condition, and it is a scandalous waste of public money to pay such cases (not a very small percentage either of the total enlistment), as they must obviously be rejected when brought up for their second medical examination in their groups. If the only object is to get numbers, surely the easier and quite as effective plan would be to distribute the money and

armlets broadcast without any inquiries or examination whatever in the first instance, but it is obviously unfair that a person physically or mentally unfit for military service should be put through the ordeal of enlistment at an expense to the public, without the slightest prospect of his services being of any use to his country."

The Doctor's Bill. THE question was bound to crop up soon after the New Year, and here it is! The doctor's bill, always a *bête noir*, is necessarily a heavier burden than usual in these troublous times, and several people have been moved to write protesting letters to various papers. One writes to the *Bulletin* as follows:—"The doctor's bill has just come in, and I observe with horror that there is no reduction in this year of want." The doctor also mayhap observes with horror that there is no reduction in his rent, very little in his rates, and a serious increase in his petrol, his coal and his foodstuffs. It also may happen that what little leisure he can snatch he is gratuitously devoting to the public service by helping at a hospital, giving lectures to nurses, and doing the club work of a friend absent on military duty. Patients are too apt to imagine that a doctor, being a gentleman, is possessed of private means, and in bad times can as easily reduce his fees as a great landlord can reduce his rents. The real fact is that bad times hit a doctor more severely than most, for more than half the money he earns he cannot touch, and many of his debts are hopelessly bad.

It would be difficult to find a more flagrant example of abominable treatment of a doctor in the matter of fees than that which was disclosed in an action brought by Dr. H. A. Mason, of Duffield, against a Mrs. C. A. Scott, of Eastbourne, for the fees which the lady had verbally guaranteed to pay in respect of attendance upon her deceased mother. As the undertaking was not in writing, the liability was repudiated.

"His Honour said he came reluctantly to the conclusion that defendant must succeed. That was not a court of morality or ethics, and he was not there to express views as to the propriety of the conduct of the defendant and her husband; but being human, he wished he could strain the law so as to make them responsible for what in his opinion morally they undertook to do. He should have thought that any affectionate daughter would be ashamed not to undertake that responsibility, more especially in this case as she was in a good position and her mother was ill able to afford the payment. There was no liability on defendant's part, however, and he accordingly gave judgment for her, though he made not order as to costs." Comment is superfluous.

Mr. Barker Better THE following gem, which recently appeared in the *Daily Sketch*, is sent to me by a correspondent for my views. On the subject of Mr. Barker I have no views, for I know very little about him. He appears to have a good many friends in the Press, one of whom seems to be a very indifferent journalist. To confuse the

General Medical Council with the British Medical Association is like confusing the High Court of Parliament with the Court of Aldermen, and to suggest that the General Medical Council, a judicial body, is a trade union is to display the crass ignorance of the bumptious penny-a-liner.

"Mr. H. A. Barker, the famous bone-setter, has been rather seriously ill, but is now better, and I make no bones about being exceedingly pleased at his recovery. For Mr. Barker is a valuable member of the community. I won't call his cures miraculous, because the word savours of quackery, and it is against such an accusation that Mr. Barker has for years had to wage an uphill fight. He has been, and still is, up against the stiffest and most jealous trade union in the world—the British Medical Council. The B.M.C. some time ago strafed utterly, and cursed with bell, book and candle a certain doctor who was associated with Mr. Barker in his work of healing. This association, you may remember, they termed 'infamous conduct.'"

Talked to
Death.

It is stated that not less than 24 patients died in a Chicago Hospital on Christmas Day, and that the Medical Superintendent gave it as his opinion that they were all talked into their coffins. "There were about four thousand visitors during the day, and the Superintendent's view was that the unfortunate patients could not stand the interminable chatter." There is probably a great deal of truth in this view, and I have often thought that the restrictions as to visitors should be more severe than they are. A really sick man's own friends, realising his condition, may be considerate, but it is impossible to prevent another man's friends from being jubilant and relatively noisy over his convalescence. Many are the complaints of the wounded soldiers over the boredom inflicted upon them by the pious well-meaning visitor. The crowning mercy is when she leaves a tract behind her.

SINAPIS.

CURRENT TOPICS.

The Lowering of Moral Standards.

THE sudden shifting of our ethical standards, as shown by the systematic training of men for mutual slaughter, is likely to have serious consequences when the war is over and the combatants return to civil life. Just as for many years to come we shall have thousands of mutilated men in our midst to lower the standard of national efficiency, so we must be prepared for a definite lowering of the moral standards which control us under normal conditions of existence. We cannot systematically encourage human beings to shoot, stab and blow up their fellow beings without vitiating their moral outlook on social relations. For reasons which we cannot hope to fathom, Nature inflicts this indignity upon us and destroys ethical conventions which it has taken centuries to consolidate. The primitive man tears off his mask and once again indulges his sanguinary and destructive instincts. And, worst

of all, none can evade the obligation, since our very existence as a nation is dependent on our throwing all such considerations to the winds. What a change of front, to be sure! But yesterday we were moved to anger by a display of brutality on the part of a costermonger towards his donkey; to-day we applaud the blowing up of a vessel with its precious freight as an accomplishment calling for meritorious recognition of the perpetrators. Nature seems to take a malicious pleasure in keeping us in our places. We are born under conditions which will not bear thinking of, and death, as de Morny is said to have remarked, is "a disgusting exhibition." We try to educate ourselves into the belief that we are fundamentally superior to the animals by virtue of our altruistic conceptions, and then, all of a sudden, we devote our whole attention and ingenuity to making mincemeat of other human beings. We can no more alter this state of things than we can change the phenomena of childbirth and death. We must sacrifice our ideals or perish, so our ideals have to be ruthlessly trampled under foot. We cannot but pity the ministers of religion who are called upon to conciliate the fundamental doctrine of Christianity—that of non-retaliation—with the imperious call to arms, who have to preach a religion of peace and good will to men, and to inculcate upon their flock the supreme necessity for going to the front, there to revel in gore and thereby to gain the esteem of their fellow Christians. We shall be told, of course, that the soldier does not "revel in gore" any more than the surgeon who calmly amputates a damaged limb, that what we respect and admire in the soldier is not so much his ardour to kill as his willingness to sacrifice his life on behalf of his country, but these are mere sophisms which cannot satisfy the sage, though they may assuage the qualms of the unlettered. The war into which we have been plunged shows up irrefragably the emptiness of our social conventions, it affords convincing proof that the primitive man, who is lying somnolent within us, is ready and willing to spring to life and to issue forth, booted and spurred, into the sunshine, there to accomplish once again the deeds that have been his from the time of his inception. Let who can explain and reconcile these moral and physical anomalies of human life, which seem to confirm Shakespeare's lines that life

"is a tale told by an idiot,
Full of sound and fury, signifying nothing."

Second Best.

THE organisation of the medical services of the Crown in the present war has been, on the whole, so good and so successful in its results that one is naturally loth to criticise matters of detail. Moreover, criticisms, whether just or not, are likely to be met with the complacent answer that never were things so well managed as at present. Nevertheless, we feel obliged to return to a point we have previously raised—the substitution of untrained women for trained nurses in the hospital service of the Army. We have no desire to cavil at the patriotic spirit animating the thousands of earnest amateurs who have importuned the authorities with requests to be

made use of. It is right that they should be made use of, but it is as foolish to send them straight to responsible nursing duties as it would be to send the raw recruit straight to the trenches. There are large numbers of trained nurses available for army work, but no serious attempt has been made to bring them into the service: the offers of many have been treated with a bare acknowledgment. There are thousands of probationers with one or two years' hospital experience, but not one of them, as far as we can learn, has been employed in army work. Until these two classes were exhausted, not a single voluntary aider, however patriotic and high-spirited, and however well connected, should have been entrusted with nursing work. We are slow to accept the current rumour that voluntary work has displaced professional because it is cheaper. Our soldiers are entitled to the best, not the second best.

Medical Recruiting in Ireland.

WE note that His Excellency the Lord Lieutenant, who is Director-General of Recruiting in Ireland, has sanctioned the recognition of the Irish Medical War Committee as the official channel of recruiting for the medical profession in Ireland. This Committee was formed last summer at a meeting of the medical profession held in Dublin, and is, we believe, thoroughly representative, and responsible. Most of the *personnel* of the Committee is made up of representatives of the several universities and teaching bodies. These gentlemen are naturally in a position to influence the men whom the medical services of the country most require—that is to say, the young men recently qualified—though, indeed, so far no persuasion has been required to bring these young men into the service. To the representatives of the licensing bodies have been added representatives of the Local Government Board and certain other medical men holding positions of influence. The Local Government Board has exerted itself to the full limit of its powers in assisting members of the Poor-law medical service to obtain leave in order to accept commissions. The Committee as a whole will endeavour not only to gain recruits for the national medical services, but to facilitate those who wish to join in making suitable arrangements for the care of their practices.

Hospital Recreations.

PROVISION of suitable amusement for the convalescent in hospital has possibly not received due attention. Nevertheless, vacant hours spent at the ward fireside during inclement weather, or occupied by monotonous constitutionals in the grounds, if they exist, do not distract the patient sufficiently, and tend to produce *ennui* and to aggravate depression. Literature, it is true, is sufficient enjoyment for some, but many patients of the class which frequents charitable hospitals are not addicted to reading, and require something further. Where grounds of any extent surround the hospital, a few games of a light nature would be a distinct benefit, both as improving the health and causing self-forgetfulness. As regards indoor amusement, the ideal to aim at would be some large spare room or ward, which might be employed as a recreation hall, but even in the absence of such utopian circumstances, much more frolic might be allowed in the general wards than at present, provided that it was confined to certain fixed hours. Children, as a rule are well catered for, but we think there is a tendency to overlook this matter where adults are concerned. It is a mistake to do so, inasmuch as the mutual self-obsession which develops where the sick are con-

gregated militates against recovery to an extent which to the casual observer might seem hardly credible.

The Operating Theatre.

THE disadvantages of the operating theatre as such, with its single, or at most double, tables, its relatively large size, and unwieldy auditorium, are fast becoming apparent. The initial expense of such a structure is extremely heavy, the cost of heating is great, and it requires for its efficient running a number of trained nurses, constituting a drain upon the resources of the domestic staff. Inasmuch as it is usually the one available place for surgery in the institution, cases pass through the surgeons' hands at a rate which is too slow to be desirable, both in the interest of patients and hospital alike. Moreover, with our present views upon the subject of asepsis, a large audience, even at a distance, is not to be commended. Upon the other hand, if we substitute for such a theatre a series of simple operating rooms, each containing a table, steriliser, and bare necessary equipment, such a system is as cheap, and possibly cheaper from the point of view of lighting and heating, can usually, if compact, be run by one expert nurse, and enables several operations to be performed simultaneously. A few students can be admitted to each room, if desired, the only difficulty being in connection with anæsthetics, but should the resident pupil come to occupy the position suggested in a previous issue, this impediment could be overcome. It would be quite possible to have three or four such rooms in any modern hospital—even six, in series, each opening consecutively by sliding doors into the next.

PERSONAL.

SIR VANSITTART BOWATER has been elected by the Court of Aldermen an Almoner of Christ's Hospital.

COL. GEORGE D. HUNTE, D.S.O., has been appointed a temporary surgeon-general while a director of medical services.

COL. HAROLD HENDLEY, M.D., I.M.S., has been appointed an honorary surgeon to the King, *vice* Surgeon-General Sir L. D. Spencer, K.C.B., M.D., deceased.

DR. KAIKER A. ANKLESARIA, L.M.S., of Bombay, has been appointed by the Islington Guardians third assistant medical officer at Highgate Hill Infirmary. Dr. S. B. Gadgil, deputy medical superintendent, was recently granted permission to join up for service during the war.

DR. AYLMER MAY, Principal Medical Officer of Northern Rhodesia, has been selected by the War Office to undertake research work on the Western front in connection with wound infection. Dr. May, who is now *en route* from South Africa, has done valuable bacteriological research work in Rhodesia and elsewhere, especially in regard to sleeping sickness.

COLONEL A. W. SHEEN, who has been appointed to take charge of the Welsh Overseas Hospital, is to be succeeded in command of the Welsh War Hospital at Netley by Dr. Herbert G. Cook. Dr. Cook resides in Cardiff. He obtained his M.D. (gold medal) in 1893; F.R.C.S., England, 1891; D.P.H., Cambridge, 1893. He has been in practice at Cardiff for 23 years and has been closely associated with the King Edward VII. Hospital for nearly 21 years, and is now senior assistant surgeon. He is also medical officer of H.M. prison at Cardiff.

CLINICAL LECTURE

ON

CLINICAL CHARACTERS AND THERMAL CURVE OF PARATYPHOID FEVER.

By M. J. LEVY-VALLESI,

Médecin Aide-Major, Première Classe.

THE collective clinical and pathological study of paratyphoid fever which is here submitted to the reader deals with the outstanding features displayed in a series of 50 cases of that disease. Of this number of detailed observations, 28 were made and personally recorded by the present writer. For the written records of the remaining 22 cases he stands indebted to the obliging kindness of Dr. Bichelonne, Médecin-en-chef, and of his associates, M.M. Kruger, Mazoux, Jacquet, and Lamaze.

In 40 of the total number of this series of cases, the hæmoculture yielded positive results; in each of the remaining ten the diagnosis was further corroborated by the evidence of the sero-diagnosis.

THERMAL CURVE.

There is no existing curve which can be said to be actually typical of the thermometric phenomena of paratyphoid fever. Nevertheless, we may regard with special attention three general curvilinear types, and some irregular forms which do not lend themselves to any definite classification of outlines. I shall here describe three types of thermal curve:—

- (a) Curve without plateau;
- (b) Curve with elevated plateau;
- (c) Curve with low plateau.

(a) *Curve without Plateau: the Brief Type.*—Here we are dealing with the class of individual patients who arrive in hospital on the third or fourth day from the onset of the disease. The temperature is then found to be at 39° (102.2° F.) or 40° (104° F.), but this elevated standard is not maintained, as the thermometric record immediately commences to display a graded serial course of descending oscillations, which extends over a variable period of time (varying from seven to fifteen days). We have here had an opportunity of obtaining a complete thermometric tracing from an official who contracted paratyphoid fever in the course of his service. This was found to display a period of ascending oscillations which occupied five days; afterwards supervened the jagged line of descent, which extended over an interval of eleven days. Thus, if we just suppress the plateau of the thermometric tracing of a case of normal typhoid fever, we have before us a typical one of this, the brief type of paratyphoid fever.

This outline curve of thermometric tracing appears to me to be specially distinctive of the course of paratyphoid fever (it was typically displayed in 17 of the 50 cases). I cannot, however, assert that it should be regarded as pathognomonic, inasmuch as I have met with it in two cases of genuine typhoid fever. On the other hand, I must not neglect to point out the possibly determining fact that these typhoid cases had received two and four injections of anti-typhoid vaccine, respectively.

(b) *Curve with Elevated Plateau.*—This type of thermometric curve presented itself in 19 cases of the 50 observed. It represents, indeed, the thermal chart of a case of serious genuine typhoid fever with a plateau ranged at 39° (102.2° F.) or 40° (104° F.). The period of duration of the fever is

one of fifteen days, in rare instances extending to three weeks; the defervescence is a rapid one, and is completed in three or four days. It is to this variety of paratyphoid, as will readily be conceived, that the graver forms will be found assignable.

(c) *Curve with Low Plateau.*—In cases of this type the plateau is found to maintain a standard level of about 38° (100.4° F.), while the maximum period of duration is limited to fifteen days.

Intermediate types of the thermal curve of paratyphoid fever may also be described: that of which the plateau is first maintained at an elevated standard, afterwards subsides to a low; that in which there is at first no plateau, and then a low one presents itself; these are irregular types, of course, but all the examples are found to be more or less definitely assignable to respective places under the heading of one of the three above-mentioned formulæ.

PULSE.

The pulse of paratyphoid fever is found to follow rigorously the grade of the thermometric curve. Its maximum varies from 80 to 100, but we have constantly observed (in 27 of the 28 cases specially noted) that a slowing of the pulse-rate occurred at the apyretic period, when it was found to fall to even 60 pulsations per minute, and often lower (48, 52, 54). In the single case of a patient who had presented an exception to the rule just now mentioned—whose pulse continued to maintain a rate of 80—a relapse occurred afterwards. (a)

These facts deserve to be studied side by side with those which we have collected in the clinical observation of typhoid fever proper. (b)

CLINICAL CHARACTERISTICS.

Taken as a whole, the clinical picture presented by paratyphoid resembles that of a benign form of typhoid fever proper in many of the cases, although pretty often it will be found to assume the features of a grave type.

My own observations have led me to the general conclusion that the degree of torpor presented by the patient is generally less than in true typhoid fever, while the rose spots are of frequent occurrence; and, indeed, as has been already stated by others, they sometimes present themselves in such abundance that one would be led to the conclusion that we were dealing with a case of an exanthematous fever.

The pulmonary manifestations are merely of the most ordinary type (bronchitis, congestion)

Three of the observations of which we have preserved the record appear to me to be specially worthy of note.

Observation 1.—Paratyphoid with relapse. Intes-

(a) Since the above article was written, the recorded observations of a new series which included twenty cases have without exception corroborated the conclusion above formulated.

(b) A serial study which included the clinical records of 150 cases of typhoid fever has conducted me to the prognostic conclusion that a slowing of the pulse down to 60 beats per minute, or less, which in typhoid proper is of frequent occurrence—although less constant than in paratyphoid—is a very valuable sign of *definitive* recovery. In the course of those cases which are destined to subsequent relapse the pulse-rate never falls so low.

final hæmorrhage. G., *étameur*. Had been ailing twelve days at the time of his admission to hospital (insomnia, cephalalgia, angina), to which he was conveyed by an ambulance on December 16th. On examination: temperature 40° (104° F.), pulse 80, diarrhœa, outline of spleen not perceptible. Hæmoculture: paratyphoid A.

Evolution.—Thermometric curve of the type without plateau; apyrexia on the thirteenth day; apyretic period continued during three days, the pulse still maintaining a rate of 80 per minute.

On January 2nd, the temperature went up to 39.8° (103.64° F.); on the 4th the plateau was maintained at the approximate standard of 39° (102.2° F.); this level was maintained during nine days, when an abrupt descent to 37° (98.6° F.) occurred. The ascent to 39.8° (103.64° F.) had been preceded by a descent to 36.4° (97.52° F.), which accompanied an intestinal hæmorrhage of moderate intensity (extending over two days).

Hæmoculture was again practised on January 4th, and revealed the presence of the *Bacillus paratyphosus* A.

Observation 2.—Pleuro-paratyphoid pneumonia, with purulent transformation of the exudate. B., *ret.* 20. Had previously been vaccinated against typhoid fever.

Taken in the ambulance on January 13th. He had already been ill during the previous three days: cephalalgia, insomnia, epistaxis, left thoracic pains. On admission, temperature 39.8° (103.64° F.), pulse 100. Indications of a small amount of pleural effusion at the left base. During the succeeding days the temperature was maintained in the standard vicinity of 40° (104° F.); the amount of fluid pleural effusion increased, and dyspnoea developed. On the 19th, 900 c.c. of sero-fibrinous fluid were evacuated by puncture.

From the 25th to the 28th there was a period of descending oscillations, which was arrested at 38° (100.4° F.); then followed a stage of ascending oscillation, which in the course of eight days brought the curve up to a height of 40.2° (105.36° F.); during this time the pleural effusion was being slowly replaced. On February 4th, the fever again began to diminish in degree, and reached 38° (100.4° F.) in the course of three days.

In brief, we had, up to that date, had to deal with two exacerbations of paratyphoid fever, of which the first presented a thermometric curve furnished with a plateau, whereas the second had none. The diagnosis was confirmed by the sero-diagnostic demonstration of a positive at 1-500, or paratyphosus B, with the blood and the pleural fluid of the patient; while this reaction proved negative with the bacillus of Eberth.

On February 9th a rigor occurred, a "stitch in the side" developed, and the temperature went up to 40.4° (104.7° F.), and all the evidences of pneumonia of the right summit rapidly developed (stethoscopic signs, rusty sputa, etc.). A thermometric plateau of 40° (104° F.) was then maintained during a period of six days. On the seventh day there was a rapid subsidence to 38° (100.4° F.) During the next eighteen days, the temperature was maintained at that level, and above. The pleural effusion continued to increase slightly; the face was pale; there were profuse sweatings, with a slight degree of albuminuria. On March 4th, an exploratory pleural puncture yielded a purulent fluid, which contained pneumococci. The patient was then transferred to a surgical ward, where he was operated on.

Observation 3.—Paratyphoid fever. Intestinal pseudo-perforation. Death. P., *ret.* 20. This

patient had reached the twenty-third day of a fever characterised by the presence of *Bacillus paratyphosus* A, and a thermometric curve with elevated plateau, when, on the third day after the appearance of the apyretic period, all the usual indications of intestinal perforation suddenly developed, and were followed by death after two days. The autopsy showed no perforation. (A full account of the case and of the revelation of the autopsy will subsequently be published.)

To this account of a fatal case it would be very suitable to add a note of the result of a case observed by my associate M. Kruger. The latter presented a course of fever of an ataxo-dynamic type, which on examination revealed the presence of the *Bacillus paratyphosus* B. A fatal result supervened, which was due to pulmonary complications. These two cases bring the mortality in the series of paratyphoid cases studied by us up to 4 per cent.

It would not seem to appear that the difference due to the presence of the A or B variety of the specific would prove to be a factor of gravity, or was even accompanied by any special clinical indication. In the series of 40 hæmocultures which were carried out, the *Bacillus paratyphosus* A was found in 23 specimens, and the *Bacillus paratyphosus* B in the other 17.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by James Campbell McClure, M.D., Physician to the French Hospital in London, and to the Hospital for Consumption, Margaret St. Subject: "The Hydrological Treatment of Gastro-Intestinal Stasis."

ORIGINAL PAPERS.

ON THE TRAUMATIC NEUROSES.*

By D. W. HARRINGTON, A.M., M.D.,

Milwaukee.

THE importance of a knowledge of the surgical neuroses has greatly increased during the last few years especially in the larger cities. The great increase in rapid locomotion, the greater complexity of modern human relations and the increase in the number of those especially predisposed to nervous disorders with the increase of urban population justifies increased study of these remarkable neuroses. The much larger knowledge of these phenomena by the legal profession makes it imperative that we do not neglect them.

I have long had the feeling that the special training and the daily work of the average general surgeon unfits him to appreciate the finer things of the nervous system, and develops in him scepticism concerning those nervous disorders that have not a basis of visible pathology. It has not been an uncommon thing in the past to hear a railway surgeon express the opinion that the traumatic neuroses amount simply to a question of the adjustment of damages.

Undoubtedly certain persons are more susceptible to injury of the nervous system than others; many have a special predisposition to the disorders that we call neuroses, yet as good an authority as Putnam states that "it is certainly true in the great majority of cases no neuropathic tendency in the usual sense, can be detected even when severe results arise from trivial accidents."

As to the classes of persons who are most frequently affected by such accidents, those with irritable, responsive, sensitive nervous systems,

* Read before the American Association of Railway Surgeons, November 15, 1915.

those with narrow experiences, restricted lives and limited resources and income and those with very little training in self-control are most numerous. They are more common in persons taken suddenly and unawares and to whom a horror or calamity is apparent. They are less common among those injured while asleep or intoxicated. It is an interesting and significant fact that the traumatic neuroses seem to be relatively infrequent among those injured in the various sports and during the horrors of war. It is possible that the tension of expectation or anticipation may account for this fact. What the result of accidents due to aerial navigation will be remains to be discovered. (Since the European war began it has been stated by Bonhoffer and Wygandt that while there is no special war psychosis, latent hysteria, epilepsy, delirium, slight imbecility, maniac depressive or catatonic tendencies are likely to be fanned into activity. Prompt removal from the field into a zone of quiet and comfort is important both in the interests of the patient and because of the danger of the development of "mass-psychoses" or "imitation psychoses" among the troops. Among the ethologic factors in the production of these psychoses are included emotional stress, fatigue and lack of alcohol among those accustomed to its use. These factors are active even during mobilisation. In battle we have in addition physical injury; air impact from the passage or bursting of a shell is sufficient to give any degree of trauma to the nervous system even to the production of instant death. The writers strongly recommend the immediate administration of morphine 0.01 to 0.02 gm. and scopolamin .0005 to .001 gm. The percentage of these cases of psychoses in war runs from about .5 to 2 per thousand).

The traumatic neuroses may for the purposes of our consideration be classed as neurasthenic and hysterical. There is some diversity of opinion as to exact classification. A few years ago we heard of traumatic neurasthenia; later it was stated that traumatic neurasthenia was characterised by frequent signs and symptoms of hysteria. Albutt, who wrote the article on neurasthenia in the last edition of his "System of Medicine," states that the most notable change in opinion since Victor Horsley wrote the article in the previous edition was "the intrusion of various degrees of hysteria into the process." Another authority says "the psychic element is much more prominent in these cases than we used to think." An English authority (Knopp) after an analysis of 200 cases finds that 70 are cases of hysteria and 50 of neurasthenia.

Dercum says hysteria must be clearly differentiated from neurasthenia with which it has nothing in common; it may not have a single fatigue symptom. Hysteria may be as clearly differentiated from psychasthenia and hypochondria which belong in the group with neurasthenia.

All authorities agree that hysteria is a purely psychic disorder and has no fixed symptoms. It is generally agreed that neurasthenia is a definite disease of mental origin with symptoms as real as those purely physical. Much of what is called hysteria in women is neurasthenia, or what is still more common—the most common neurosis in women according to Llewellyn Barker of John Hopkins—psychasthenia. Barker says that hysteria is a relatively rare disorder.

Of the traumatic neuroses, I think, we may say that neurasthenia and hysteria are equally common, and that like other definite and distinct diseases, the one may be a complication of or be superimposed upon the other. Neurasthenics may show signs and symptoms of hysteria at times and cases

of typical hysteria may have symptoms of neurasthenia.

The special distinguishing mark of hysteria is susceptibility to suggestion. It is further marked by lack of fixed symptoms, alterations of character, convulsive crises, paralyses, contractures, anaesthetics, amnesias, great desire for attention and notice, lack of judgment, variations in mood, and action on sudden impulse.

The special distinguishing mark of neurasthenia is fatigability. It is the fatigue neurosis, the irritable weakness. It shows weak volition and weak inhibition, physical and mental inadequacy, lack of self-confidence, persistency and concentration.

Psychasthenia, often included with neurasthenia, is marked especially by fears, anxieties, obsessions, impulses rarely yielded to, sense of danger of impending occurrences, sense of incompleteness, lowered psychologic tension and forced agitations. It shows a tendency to periodicity.

Hypochondria is marked by an all compelling fear of disease, excessive psychic distortion of sensations of disease, real delusions regarding one's physical condition as compared with true neurasthenia.

Pathology.—I hesitate to say a word about pathology in relation to the neuroses. If medicine has taught one thing positively it is not to theorise. Just a word. All the nerve cells and centres of the central nervous system are present at birth. What physiologists call the organisation of the nervous system takes place later, largely before puberty but not completely before the fiftieth year of life. By organisation is meant the connecting up of the various cells and centres by the development of neuroses, dendrons, dendrites and dendritic processes. If we are ever to know anything of the pathology of hysteria I feel confident that it will reveal a weakly organised nervous system and in the case of traumatic neuroses a partially disorganised nervous system, especially in the higher and phylogenetically later developments of will, reason and judgment, volition and inhibition.

With regard to the neurasthenic groups we have reason to believe that the essential deficiency is in the protoplasm of the nerve cells. Hodge showed these deficiencies in the protoplasm of thoroughly fatigued cells in the active nerve centres of lower animals. There are probably other deficiencies of a chemical nature. Hill and Bernard in London did some experimental work showing that lax abdominal walls with naturally low blood pressure permitting the blood to leak into the splanchnic area vessels was a characteristic of neurasthenia. There is much evidence to show that the neurasthenic group is often associated with the lowered conditions accompanying organic disease such as chronic tuberculosis, cardiac disease, arteriosclerosis and some organic diseases of the nervous system.

Age.—The neuroses seem to belong chiefly to the period of life from puberty to middle-age. Neurasthenic conditions are most frequent from 20 to 30 years of age. When neurasthenic symptoms appear after 50 one should search very carefully for some organic disease. Hysteria is most common from 20 to 40 but may appear at any age. Children resist the shock of accidents well, old age badly; it frequently precipitates premature senility.

Sex.—Women are more subject to the hysterias, mild neurasthenia and especially to psychasthenia. Men more frequently have the severe neurasthenias and hypochondria, and we know now that traumatic hysteria is much more frequent in men than was formerly thought. Women are more frequently afflicted than men in proportion to the number exposed to accidents and are slower to

recover, but as men are more frequently exposed to violence the majority of cases that come before us for examination are men. Cabot says labouring men have no right to such troubles as neurasthenia, but we find that the traumatic neuroses are not uncommon among them and they seem to be more common than formerly.

Diagnosis.—The viewpoint of the practical surgeon employed by a corporation and the modern neurologist is quite different. I think there is a middle ground where reasonable neurology and practical common sense may meet and in a measure agree. Our chief difficulty is in diagnosis, in the proper estimation of the value of signs and symptoms. Many of the subjects that come before us are interested in making out a case, in some cases wilfully, in others unconsciously. It is well to start with Weir Mitchell's admonition to "watch her enter the room." Another of the wise ones, Osler, says, "Observe him as he enters the room, his clothing, manner of carriage, facial expression, the humour he is in. The appearance of the patient is often quite characteristic, suggestive but difficult to describe." Osler further says "neurasthenia is a disease above all others which has to be diagnosed from the subjective statements of the patient and from an observation of his general behaviour rather than from the physical examinations." In hysteria the facts stated by the patient help but little; the method of stating them may help much. There is a diagnostic value in the rather extravagant language in which the trials and sufferings are related and in the unusual features and the halo of mystery with which an attempt is made to surround the case. It is very important to let the patient tell his own story and tell all there is to the case; avoid suggestion in the way of question. As one authority puts it: "The pain that is not, when asked for, soon becomes." The same is true of other symptoms.

We can hardly speak of an acute neurasthenia, though a quite abrupt appearance may show itself after unnoticed premonitory symptoms. But as a rule, neurasthenia is of gradual development through weeks or perhaps months after an accident; in some cases it may seem to develop out of the depression of the surgical shock if the accident involves severe physical trauma. But the depression of surgical shock is not neurasthenia. Hysteria may appear immediately after an accident, or it may appear suddenly or develop gradually after a so-called latent or "incubation" or "meditation" period. During this period the patient has time for the direction of concentrated attention to the accident, often to the particular part of the body involved or supposed to have been involved in the accident. During this period of meditation there goes on quietly the work of autosuggestion that finally develops the hysterical outburst. Traumatic hysteria differs from the ordinary hysteria of constitutional origin in that the outburst is often preceded by an unnatural calm; this seems particularly true of post-operative hysteria. It also differs in that it does not often show so many of the ordinary signs and symptoms; it is more likely to show major seizures; it is also more likely to be a mono-hysteria, for instance, an injury to a limb may be followed by a hysterical contracture involving that limb only.

Pain is a prominent symptom in both varieties of neuroses, and as in many other diseases, is often the first and most prominent symptom in the complaint. The average mind instinctively associates pain with injury, and, in making out a case, will emphasise, often overemphasise, the pain present, whether it fits into the rational symptomatology of the case or not. This is especially true in hysteria; the pain is agony. Speaking of pain in

hysteria, Starr says: "It is very acute and the patients appear to suffer intensely. It is more agonising than any disease of the organ could give. These are mental pains, true hallucinations of pain and are little affected by analgesic remedies, even hypodermics of morphine, except as these act by suggestion; these pains are often suddenly relieved by suggestion. In these cases joint pains are not attended by other signs of joint inflammation except spasm of the muscles on moving the joint." Starr quotes a case of such joint pain that, when the joint was amputated, appeared in the corresponding joint of the other limb.

Pain in the back is almost a constant complaint in both varieties of traumatic neuroses. It may be limited to certain spinous processes, with radiations from then, or it may be quite diffuse. Undoubtedly much of the pain in the lower back is real pain due to strained muscles and ligaments of the back in falling or resisting fall. Herbert Page believes that even where there has been no violence at the moment of jar or shock the lumbar and dorso-lumbar muscles, ligaments and articulations are thrown into such sudden stress and strain that pain, muscle spasm and deep tenderness are the legitimate result. Such pain is not part of the neurosis but is referred to because it is so very common in these traumatic cases.

The pain in neurasthenia is less severe than in hysteria; there is pain and tenderness in the nape of the neck and over the spinal processes, in the head, tenderness of the scalp, hyperæsthesia of the skin, sensitiveness of internal organs. Mental pain is often pictured in the face. The special senses are often acutely sensitive. The threshold of pain and sensation is often far above the normal. The headache of neurasthenia is usually occipital; it may be frontal. The headache is not a sharp pain but rather a strange band-like feeling. The feeling of pressure within the head is quite constant.

In traumatic hysteria two symptoms most frequently met are paralysis and anæsthesia. They are usually associated; of course, there may be much anæsthesia without paralysis. Motor paralysis in these cases means a mental inability to initiate volition. Paralysis on the left side seems to be three or four times more frequently found than on the right side. According to Burt, paralysis of the left arm and much less complete paralysis of the lower limb on the same side is most frequent. According to others the lower extremity is more frequently affected than the upper. In hysteria, as a rule, the paralysis is more complete than organic paralysis. There is never loss of the knee jerk as in organic paralysis. The knee jerk is usually increased but the whole leg or body is jerked. True ankle clonus is never present. The movement is an irregular to-an-fo movement. True Babinsky's reflex is never present. One can often succeed in developing sufficient voluntary motion in these cases to differentiate them from organic paralysis. Minor degrees, amounting to weakness of the part often follow trifling injuries. In extreme cases there may be very complete paralysis of large portions of the musculature of the body.

Anæsthesia and analgesia are very common. They are irregular in area, not corresponding to nerve distribution. The injured part may show anæsthesia especially if it be a limb. The chest shows none, as a rule, the head and particularly the face less than the limbs. The area is often glove-like, the sleeve-cuff or stocking-form. There are often patchy and variable areas; it comes and goes readily. Anæsthesia of the mucous membranes is more frequently found than has been thought. An authority says "the anæsthetic conjunctiva is the mark of hysteria." It is well to test the nares for

sneezing and the fauces for retching. The pain sense is more completely absent than in organic trouble. The outline of areas is better defined than in organic disease.

It is stated that concentric contraction of the field of vision may be the only positive sign of hysteria present. The field of vision may be of the "shifting type," narrowing during the examination. There may be partial or total deafness on either or both sides, usually on the side on which the cutaneous anæsthesia is well marked. In mild grades of hysteria hearing may be exceedingly acute. The "irritable eye," irritable to light, belongs to neurasthenia, but the victim of hysteria prefers a darkened room. Colour vision should be tested; the red field may be larger than the blue, which is contrary to the normal condition. One object may appear as several. A familiar object may not be recognised by vision, yet readily recognised by feeling it. One may be able to recognise very small objects, but not large ones. In these cases the examiner should not be too ready to assert that the person is indulging in conscious deception.

Tremor is frequently found in both hysteria and neurasthenic cases. In typical traumatic neurasthenia a fine tremor is almost constantly found about the eyes and often in other parts of the face. A fine tremor of the tongue is very common; tremor is not likely to be found in the case of a malingeringer, unless possibly in the case of a victim of alcoholism. Severe fright may give rise to a tremor which may become permanent.

In hysteria there may also be a very fine tremor often seen in the hands, at times in the face or tongue, not unlike the tremor of alcoholism. The tremor of hysteria is often coarse and jerky.

There is a characteristic tremor that belongs to "an obscure traumatic degenerative psycho-neurosis analogous to a severe form of paralysis agitans" (Putnam). The hysterical tremor in some cases is of the type of intentional tremor.

The more carefully the convulsions of hysteria are analysed the less they appear like those of epilepsy. The initial cry, the lack of suddenness of the fall, the character of the movements are all different. The epileptic convulsion rarely lasts longer than a few minutes, the hysterical often very much longer. The former are rarely immediately repeated, the latter frequently. The movements of the hysteric usually partake of the character of a purposeful struggle. Epileptic convulsions are most frequent at night or in the early morning; hysterical in the day or evening, after some excitement and always in the presence of some audience.

We should not lose sight of the fact that the traumatic neuroses may be present with organic disease; their symptoms may easily lead one to overlook the early stages of organic disease. One should inquire into the health of the patient for some considerable time previous to the alleged injury. An apoplexy may have caused the fall and the paralysis rather than the sudden movement of a car, or the shock of an accident may have superinduced an apoplexy in a subject already prepared to have one. Hysterical symptoms with an intentional tremor may all be the symptoms of a multiple neuritis, and in some cases it may be very difficult to make a differential diagnosis. A number of organic brain diseases such as tumours in their early stages, trauma with microscopic hæmorrhages or other lesions, hæmorrhagic meningitis and septic encephalitis may cause typical outbursts of hysteria. Other diseases and organic lesions in their early stages give origin to typical neurasthenic symptoms. One should always be on the look-out for tabes, paresis, multiple sclerosis, arteriosclerosis and especially the conditions that lead to an

apoplexy, chronic tuberculosis, cardiac diseases, the true insanities, and Albutt emphasises rheumatoid arthritis.

According to Dercum, the traumatic neuroses never originate the true insanities. Of course, a person with a strong predisposition to insanity after trauma or severe shock may become insane and the trauma or shock may have acted as the exciting cause.

During late years we have been learning that in the production of the traumatic neuroses the psychic factor is much more prevalent than was thought. We are learning that mental or emotional shock gives just as pronounced and troublesome symptoms as actual lesions of nerve tissues. We are learning that physical violence of the most trifling character may give intensified symptoms if it so disconcerts the victim that he cannot call into use the protective power of the will, or if the violence is of such a kind, as, for example, injury to the head, as to create apprehension of trouble to come. We are also coming to realise that what otherwise might be an innocent matter may become a serious and prolonged trouble if accompanied by severe pain and loss of sleep and that the proper management in the beginning of traumatic hysteria may save great distress and expense.

We are learning that injuries of moderate severity such as jars or falls without fracture or serious visible contusion may cause actual lesions of nerve tissue, minute hæmorrhages in the brain or cord, necrosis of nerve elements, and widespread vasomotor disorders, with typical traumatic neuroses as the only symptoms, just as they may be the only symptoms in the early stages of brain tumour. We are learning that many persons have diseases or disorders in a latent form or a latent tendency to disease that may be rendered active by physical or psychic trauma.

The diagnosis in these cases is often complicated by a variety of interests, medico-legal and others. Conscious simulation is often present. Unconscious simulation is largely in proportion to the degree of hysteria present, but that is the way of hysteria, and the person is not to be charged with feigning and fraud. The worry over legal complications, loss of work, expense which is always a serious matter to the poor, the possibility of permanent invalidism, all these play their part in affecting the course of the trouble and in making the case difficult to manage.

Scientific conclusions must be arrived at chiefly in those cases developing after accidents in which there is no possibility of making claims for damages or insurance. The tendency has been not to give these cases due consideration especially where there has not been gross physical injury.

Prognosis.—According to Bilstrom, a Swedish writer, complete recovery occurs in about 90 per cent. of the cases. The longer the interval the larger the percentage of complete recoveries. If a complete settlement could be made immediately it would shorten the course of many cases. Unfortunate suggestions and repeated examinations render the prognosis less favourable, especially in hysteric cases. The local or mono-symptomatic cases of traumatic hysteria do the best; as previously indicated, these are not likely to have a constitutional hysteric basis. Uncomplicated neurasthenia makes a good recovery as a rule. Complicated cases and those with a marked constitutional basis are often slow and trying. Strümpel says: "We know of many cases where such patients, in spite of the fulfilment of every desire, have lived for years in a state of permanent neurasthenia, incapable of anything, and finally have fallen into a state of profound mental dullness."

CURRENT INCOME TAX AND ITS INTEREST TO THE MEDICAL PROFESSION.

By ERNEST EVAN SPICER, F.C.A.,

Author of "Income Tax and the War"; "Income Tax, 1915-1916 and Before"; "Income and Super-tax and its Legal Evasion"; "Income Tax Claims and Appeals," etc., etc.; Joint Author of "Income Tax in Relation to Accounts," etc., etc.

THE increases in the various Rates of Income Tax which have been made since the commencement of the European War, and especially those now in force under the provisions of the Finance (No. 2) Act, 1915, cannot fail to be of interest to the Medical Profession, and it is desirable that all those who are called upon to contribute to the State in respect of this Tax should be alive, not only to the Rates in force, but also the rights and privileges which the various Acts, making up the Income Tax Code, give to the taxpayer.

The Standard Rate of Income Tax at the present time is 2s. 6d. in the £, with Lower Rates applicable to Earned and Unearned Income under certain conditions. For the Fiscal Year 1915-16 these rates are increased by 20 per cent.

So far as the payment of Tax is concerned, the amount due under the first Finance Act, 1915, is payable on January 1st, 1916, and the Additional Percentage, which is added by the Finance (No. 2) Act, 1915, is payable on July 1st, 1916. This, however, only applies as far as the Profits from carrying on business are concerned.

In future years it is proposed that the whole Income Tax for the year shall be payable, one half in January within the Fiscal Year, and the other half in the following July.

Earned Income.—Where the Total Statutory Income of a person, including that of his Wife, does not exceed £2,500, such person may claim to be assessed in respect of the Earned portion of the Income as follows:—

Where the total Income exceeds	But does not exceed	Rate of Tax on Earned Income.
£130 ...	£1,000 ...	1s. 6d. in the £.
£1,000 ...	£1,500 ...	1s. 9d. "
£1,500 ...	£2,000 ...	2s. 0d. "
£2,000 ...	£2,500 ...	2s. 4d. "
£2,500 ...	—	2s. 6d. "

and these rates are increased for the year ending April 5th, 1916, by 20 per cent., and in the year ending April 5th, 1917, subject to any subsequent legislation, by 40 per cent.

It was formerly necessary to claim this Relief before September 30th of the Year of Assessment, but this limit of time has now been removed.

Unearned Income.—Where the Total Statutory Income of a person, including that of his Wife, does not exceed £500, such person may claim Relief in respect of the Unearned portion as follows:—

Where the total Income exceeds	But does not exceed	Rate of Tax on Earned Income.
£130 ...	£300 ...	2s. 0d. in the £
£300 ...	£500 ...	2s. 4d. "

and these Rates are increased for the year ending April 5th, 1916, by 20 per cent., and in the year ending April 5th, 1917, subject to any subsequent legislation, by 40 per cent.

In the majority of cases the Tax on Unearned Income will be collected at the source, and in order to obtain the Relief, a Claim for Return of Tax will have to be made after the expiration of the Year of Assessment.

Statutory Income.—It must be noted that in order to avail himself of the foregoing Rates in respect of Earned and Unearned Income, the Statutory Income of the person concerned must be within the limits named. In this connection it is important to observe that the Statutory Income is

not the Actual Income, but the average of the three years completed prior to the commencement of the Year of Assessment—i.e., April 6th.

The Profits or losses of these three years have to be adjusted in accordance with the Rules and Regulations of Income Tax—e.g., certain items of expense are not allowed in computing the liability.

Exemptions.—The person whose Total Statutory Income does not exceed £130 is exempt from Income Tax, and where any portion is Unearned, and Tax has been deducted at the source, a claim for repayment of such Tax can be made.

Abatements.—Persons whose Statutory Incomes do not exceed £700 are entitled to treat a portion of such Income as not taxable. An abatement is allowed in respect of this portion, and Income Tax will be payable on the remainder. The abatements now in force are as follows:—

	Abatement.
Where the Total Income does not exceed £400 ...	£120
Where the Total Income exceeds £400, but does not exceed £600 ...	100
Where the Total Income exceeds £600, but does not exceed £700 ...	70

Allowance for Children.—A person whose Statutory Income does not exceed £500 is entitled to an additional abatement of £25 in respect of each Child under the age of 16 years living at the commencement of the Year of Assessment.

Life Insurance.—An additional Abatement is allowed in respect of Life Insurance Premiums up to an amount not exceeding one-sixth of the Total Statutory Income. In calculating the Life Insurance Premiums, however, it must be remembered that Relief will not be granted in any year in the case of any premium for securing a Capital Sum payable on death, to an extent greater than 7 per cent of the Capital Sum insured.

It must also be remembered that the limit allowed in any year in respect of Premiums for securing benefits other than an amount payable at death—e.g., Deferred Annuities—is £100.

Life Insurance Premiums payable in respect of a Policy on the life of the Wife of the Taxpayer may be claimed within the limits above mentioned.

For the Income Tax years 1914-15, 1915-16, and any subsequent year during part of which the European War continues, the Relief granted in respect of Insurance Premiums may be claimed on the basis of the Statutory Income for the year ending April 5th, 1914, if this basis is more advantageous than the Statutory Income of the Actual Year.

Any Tax overpaid for the year 1914-15 can be reclaimed, the concession being retrospective to this extent.

Concession with regard to Percentage Addition to Rate in the Case of Reduced Incomes.—If an Individual who has been assessed to Income Tax claims and proves that his Actual Income from all sources during the Fiscal Year 1915-1916 is less by more than 10 per cent. than the Income on which he has already been assessed, he shall be entitled to repayment of either the whole or a proportion of the additional 20 per cent. Tax paid by him in accordance with the following Table:—

Percentage by which the Actual Income is less than the Income on which Income Tax has been assessed or charged.	Amount of Repayment of Additional Tax.
11 per cent. and under 12 per cent.	10 per cent.
12 " " 13 " "	20 " "
13 " " 14 " "	30 " "
14 " " 15 " "	40 " "
15 " " 16 " "	50 " "
16 " " 17 " "	60 " "
17 " " 18 " "	70 " "
18 " " 19 " "	80 " "
19 " " 20 " "	90 " "
20 " " and more	100 " "

Reduction of Income owing to the War.—In cases where the Adjusted Profits of the Year of Assessment are proved to be less than the average of the last three years, including the Year of Assessment, and it can be shown that the diminution is due directly or indirectly to the War, Income Tax may be recovered on the difference between the amount of the original Assessment, and of the new Average so taken, or of the Actual Profits, whichever are greater.

If, however, the Taxpayer is serving with the Military or Naval Forces, or abroad with the British Red Cross Society or the St. John Ambulance Association or other body with similar objects, he can get the Assessment reduced to the Adjusted Profits of the Actual Year, even though these are smaller than the New Average.

Application of pre-War Rates.—If any person who has served or is serving as a member of the Naval or Military Forces of the Crown, or on Naval or Military service in connection with the European War for which payment is made out of moneys provided by Parliament, or in Red Cross or Ambulance work abroad, proves that his Total Income from all sources does not exceed £300, he may claim to pay Tax at the rate in force immediately before the commencement of the War.

If his Total Income does not exceed £160 he will be exempt, otherwise he will be entitled to an abatement of £160, but his allowance in respect of Life Insurance Premiums or Children will be as previously stated.

Super-Tax.—Super-Tax is an Additional Tax payable by all persons whose Statutory Income for the year preceding the Year of Assessment exceeds £3,000, and the Tax is payable in those cases on the amount by which such Income exceeds £2,500.

The following is the present scale of Rates:—

In respect of the first	£	Nil	=	£	s.	d.
2,500	Nil		=	Nil		
next 500	10d. in the £		=	20	16	8
1,000	1s. 2d.		=	58	6	8
1,000	1s. 6d.		=	75	0	0
1,000	1s. 10d.		=	91	13	4
1,000	2s. 2d.		=	108	6	8
1,000	2s. 6d.		=	125	0	0
1,000	2s. 10d.		=	141	13	4
1,000	3s. 2d.		=	158	6	8
And the remainder	3s. 6d.					

As stated above, the Assessment to Super-Tax is made on the Statutory Income of the previous year—i.e. the Total Income of the previous year for Income Tax purposes arrived at in the Statutory manner.

Where the person liable to Super-Tax can prove to the satisfaction of the Commissioners that his Actual Income from all sources in the current Income Tax year is, or will be, less than two-thirds of the amount upon which he is liable for Super-Tax, he is entitled to postpone to January 1st, 1917, the payment of that proportion of the Super-Tax which represents the difference between Tax on the Income assessed and Tax on the Income of the Actual Year.

In the case of persons serving with the Military or Naval Forces of the Crown, or engaged in work abroad in connection with the British Red Cross Society or the St. John Ambulance Association, or any other body with similar objects, such person can under similar circumstances have the Super-Tax Assessment reduced according to his Statutory Income for the Actual Year.

Excess Profits Duty.—The Excess Profits Duty which has been established by the Finance (No. 2) Act, 1915, will not apply to the Medical Profession.

A SIMPLE METHOD OF ABORTING MIDDLE-EAR INFLAMMATION AND INFECTION LEADING TO MASTOID ABSCESS.*

By FRANK E. MILLER, M.D.,

New York.

FOR the past twelve or more years the writer and his two assistants, although treating a large number of cases daily, have had no cases of middle-ear or mastoid abscess. By that is meant not one case that has come to us before suppuration had been formed has been allowed to result in abscess. In other words, the pus-forming and mixed-infection elements which, although tending toward and by natural process, unrestrained, would have resulted in abscess, have been aborted.

Believing this record and my method of securing these results would be of interest not only to those engaged exclusively in ear, nose and throat practice, but also to the general practitioner, who of necessity must see and treat such cases from time to time, this brief article is offered in the hope that it may be helpful to others.

The general practitioner knows full well the tendency of middle-ear infection, suppurative and non-suppurative, to eventuate in abscess, and to extend to and involve the mastoid cells. A practicable, safe means of preventing such involvement, with its serious complications, may be described as follows:—

Morph. sulph., gr. $\frac{1}{4}$.

Atropin sulph., gr. 1-150th.

Sol. adrenalin chloride, gtt. x.

Petrolati q.s. ad (Sten'l), oz. i.

The internal ear is first cleansed as thoroughly as possible, preparatory to the application of more affirmative remedial measures. A sterilised Eustachian catheter covered with Meg. M. A. A. Co., morphin and atropin sulph. (gr. 1-4 and 1-150) is inserted into the internal ear, and any pus or other infectious material drawn off by aspiration. This preliminary step, for obvious reasons, is important.

The patient's head is now reclined upon a pillow, so that the external auditory meatus presents what may be likened to the flaring part of a funnel, formed by the auditory canal.

Into the canal is placed a 4 per cent. solution of cocain, so that if the tympanum is intact there is a small "puddle" of the solution, into which from two to four hypodermic tablets (containing morphin gr. 1-4, atropin gr. 1-150, each) are dropped, and as the cocain anæsthesia permits, gently stirred in the solution until fully dissolved. The cocain is for quick anæsthesia; the morphin-atropin combination to prolong the anæsthetic state during and after the further treatment.

A small can of antiphlogistine, previously heated in a water bath or pan of boiling water, is made ready. When at a comfortable temperature, a piece of sterile absorbent cotton is loosely wound round a wooden tooth-pick or other clean stick (of just sufficient size to go into the ear canal up to the tympanum, but not large enough to irritate or impinge on the sides of the canal) and the remedy smeared over the cotton. This is then carried into the ear and carefully placed there, and a pledget of clean cotton placed over all to protect the ear-cavity from without. The application is allowed to remain *in situ* for forty-eight hours before removal. This must be insisted on to secure the results desired.

At the expiration of the forty-eight hour period the ear is washed out, and the otitis media, mastoiditis, etc., have disappeared. Please understand,

*Reprinted from the *New York Medical Times*.

the remedy is placed right into the ear-canal, through the external meatus. This, on account of the anæsthesia already secured by the cocain and morphin-atropin applications, is practically painless, and hence practicable. If the tympanum should be so swollen and bulging and immediate destructive process is indicated, so that it cannot be saved, it can be punctured without any pain under this local anæsthesia. There is nothing harmful in this application, and I have never had any untoward results from the use of the above-mentioned preliminary treatment for securing anæsthesia. Even as high as four tablets of the morphin-atropin combination have been safely used in cases of children, even with perforation; but I would distinctly advise against morphia and atropin tablets, or otherwise, in cases of perforation of tympanum; it might be large enough to allow leakage into the mouth, causing nausea and sometimes poison to patient. This so anæsthetises the ear as to make the application and packing of the remedy tolerable. Without this precaution the patient could not endure the packing of the ear with the remedy mentioned. Usually, after the case is treated in this manner, the patient goes off to sleep for several hours, and when the packing is allowed to remain in place, undisturbed, for the forty-eight hours, the patient remains fairly comfortable. If it is removed (as has been done in some instances by other medical attendants) the pain is severe and the whole thing must be done over again. From my personal experience, therefore, I am able to state that it is the most certain, painless and practical method of treating and aborting middle-ear and mastoid complications I know of, and its apparent success leads me to send this to you, and trust the adoption of this method will lead others to the same success I am having.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

DR. T. A. WILLIAMS' LECTURE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Nothing is more pleasant to a conceited man than to be able to say, "I told you so." This I think I am entitled to do with regard to the main argument suggested by Dr. T. A. Williams' lecture in the last issue of your admirable paper. I am glad that through your courtesy I am able to conceal myself under the *nom de plume* which I am allowed to use, and am not open personally to the gibe I very likely deserve. Your readers may recollect that a lengthy correspondence on the subject of neurasthenia took place in your columns some months ago. I then insisted that the term "neurasthenia" was loose, misleading, and unscientific. I urged that neurasthenia was in fact a meaningless term, used improperly to designate a multitude of symptoms which, displaying themselves through or within the nervous system, were really due to a great variety of totally different causes. "Neurasthenia," like dyspepsia, has become a popular term, and a term most useful to a certain species of quacks. It ought to be discarded by medical men. No medical man, writing scientifically, speaks of dyspepsia as a distinct entity. This malady to the uninstructed patient means any pain or discomfort at any part of the digestive system. In this sense dyspepsia may be functional disorder due to such a cause as mental

shock or prolonged grief, or to temporary or prolonged improper dietary. On the other hand, its cause may be any one of a score or more of distinct pathological processes. It may be due, for example, to ulcer of the stomach or intestine, to disease of the liver, to chronic appendicitis or hernia, or to morbid growths of many kinds. To label all the symptoms arising from these conditions dyspepsia is not more absurd than to designate all the functional nervous affections so lucidly described by Dr. Williams as neurasthenia. It would be impertinent of me to try to add to Dr. Williams' extremely valuable contribution towards elucidation of the problems with which he deals. His lecture stands out prominently among the most valuable in the long series that have appeared in your pages. It is to be hoped that its existence may be prolonged beyond ephemeral journalism, and that it may be embodied in some important permanent work which he may later produce. I must congratulate you, Sir, on the fact that you now seem to attract to your clinical pages some of the best writers in both hemispheres. It must be a source of gratification to Britishers that Dr. Williams is a graduate of a great British University. Everyone who knows anything about Harvard knows that this ancient and famous University has the opportunity and the means of attracting to its professorships the best intellects in the world, and Dr. Williams' lecture furnishes a good example of the work which these men are carrying out.

I am, Sir, yours truly,
AN OBSCURE PRACTITIONER.

ABOUT EPIDEMIC NEPHRITIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In a clinical note on epidemic nephritis, communicated by me to the MEDICAL PRESS some months ago, I hazarded the view that the ailment was possibly a renal manifestation of some modified form of enteric fever. I based this view on the presence of *Bacillus coli* in the urine, observed by me after the original attack.

Captain Langdon Brown controverted these opinions very emphatically, and, metaphorically, wiped me out.

I find, however, in a report of the proceedings of the Vienna Academy of Medicine, published last week, that opinions very similar to mine were expressed as to the causation of epidemic nephritis in the Germano-Austrian armies.

Osler, moreover, appears to admit very distinctly that in certain forms at least of enteric fever the kidneys are markedly affected.

I am, Sir, yours truly
J. C. McWALTER.

Dublin, January 18th.

SOME BRITISH MEDICAL MEN OF LETTERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read Mr. Maidlow's paper in your last issue on "Some British Medical Men of Letters," liking it much. From the title one concludes that the author has not exhausted the subject, whilst should he be collecting data two points that occur to me may interest him.

Carlyle's brother was a doctor. Practised in Rome, retired, and when Thomas was offered his Doctorate of Laws at Edinburgh he refused the same on account of the confusion that might occur between the two. The brother, Dr. John Aitken Carlyle—I blush when I mention such a solecism or

barbarism—Turned Dante's Infernoal hexameters into prose (!) English.

Then, of course, we have our own laureate, who singeth in sorrowful numbers, Dr. Bridges.

It may be my fate to be laureate,

The honour I do decline.

I can't sell my brains to wipe out old Stain(e)s
And work for a stoup of wine.

I do not give forth this distich in the hope that Mr. Maidlow will add me to his Pathenon, but to draw the attention of poets to the fact that in old time it was a recognised axiom that the chariot wheels of the Nine needed oiling.

I am, Sir, yours truly,

JOHN FURSE McMILLAN.

Sandown, Isle of Wight,
January 19th, 1916.

DIET AND THE CARE OF CHILDREN'S TEETH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I read with great interest the article on the above subject by Mr. Sheldon Friel, which appeared in the MEDICAL PRESS AND CIRCULAR of January 19. It seems to me that the diet schemes suggested would be excellent for the teeth of children, but that unfortunately such diet would not suit the insides of all children. My own experience with small boys, and that of several mothers of my acquaintance, is that even the smallest quantity of fruit, in some cases even a tiny portion of jam, causes the child to lose all control of the bladder and may also cause diarrhoea. Oranges and melons are very severe to some children. Moreover, many children under seven will refuse to eat any sort of food with a distinct taste, as, e.g., radishes. Even with great care and watchfulness a child will fill its mouth too full on the first opportunity, and I fear that if the meat is cut in 1-inch pieces the coroner may get some extra work. I hope to take advantage of much sound advice in the article, but these few drawbacks have occurred to

Yours truly,
DOCTOR'S WIFE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I should be grateful if you would allow me to comment on some points in Mr. Friel's paper on "Diet and the Care of Children's Teeth." As a mother who has taken personal care of all her children, I beg to differ from the author in some details.

If I gave my boy of 4 years, or my girl of 2 years, fruit, raw or cooked, or raw vegetable such as radishes, celery or salad, their digestion would be seriously diorganised for a considerable period. My experience of giving children under 6 years old meat cut in large pieces is the child either swallows it whole, chokes, or puts it out of its mouth and refuses to eat it.

I entirely agree with many points in the paper, but in others it may be misleading to young, inexperienced mothers whose children's digestions might be injured by carrying out the rules to the letter.

I am, Sir, yours truly,
MOTHER OF A FAMILY.

MILITARISATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—No doubt the remarks of "Sinapis" in your issue of last week and previously are in some respects justified, but much might be said on the

other side. However, I wish to comment on only one point—the alleged incongruity of consultants' status and appearance with military rank and uniform. As I understand it, they—or most of them—undertook years ago that in the event of war they would put themselves at the disposal of the Government, and their commissions, which carry rank and uniform, are evidence that they are working under the King's Regulations and thereby are spending much time and skill and sacrificing much money in the service of the Empire, besides being liable for further duties if required. Some may not care for the rank, and some may doubt whether a uniform is becoming, but others may be proud of both, for sentimental reasons (not mere vanity), which cannot be appreciated by anyone in whom the feeling is not innate. In no case is chaff likely to be relished, and as there is no option in the matter, and no practical result is likely to be brought about by criticism, I venture to suggest that "Sinapis" might let the subject drop.

At any rate, as the joke about personal appearance has been doing regular duty for some time, I beg leave to recommend it for a long furlough, or even honourable (but permanent) discharge.

I am, Sir, yours truly, but
London, N.W. NOT IN KHAKI.
January 22nd, 1916.

[Very well, I agree. Enough said; at any rate for the present.—SINAPIS.]

SPECIAL CORRESPONDENCE.

FROM OUR OWN CORRESPONDENTS.

SCOTLAND.

INSURANCE ACT PAYMENTS IN EDINBURGH.

The following figures are given for the years 1914 and 1915. Payments to panel chemists—1914, £6,898; 1915, £5,823. The latter figure, however, is the net amount after a deduction of, in round numbers, £120, which has been retained pending a complete check of the prescription forms. The payments to doctors are shown in the following table:—

	1915.		1914.	
	(1s. 4d. per person.)	(1s. 9d. per person.)	(1s. 4d. per person.)	(1s. 9d. per person.)
	£	s. d.	£	s. d.
1st quarter ...	6,248	0 0	7,809	12 0
2nd ..	6,328	2 8	7,743	0 2
3rd ..	6,386	4 0	8,026	5 7
4th ..	6,487	4 0	7,223	5 5
	£25,448	10 8	£30,802	3 2

The list of doctors under agreement, as revised this month, includes 119 names; there are 109 chemists.

FINANCES OF THE EDINBURGH ROYAL INFIRMARY.

THE effect of the war, with its accompanying rise in the price of materials, on the cost of carrying on the Royal Infirmary, was reflected in some of the speeches made at the adjourned general meeting of the Court of Contributors held last week. It was remarked that two new records had been established during 1915: first, that there had been more patients than ever before; and secondly, that on a single day there had been very nearly 1,000 inmates. As regards the future, now that contracts are expiring, higher prices will require to be paid for everything. To an institution which consumes about a thousand quarts of milk a day, and nearly half as many pounds of beef, a rise of a penny a quart or pound

is a serious additional charge. Professor James Ritchie, Convener of the House Committee, said that with the lapse of contracts they were faced with an entirely different state of matters, and he had come to the conclusion that they would need at least £5,000 more income to maintain the same financial position as in 1914-15.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, NOVEMBER 19TH, 1915.

The President, GIBBON FITZGIBBON, M.D., in the Chair.

EXHIBITS.

PAPILLOMA OF THE VULVA.

DR. BETHEL SOLOMONS showed two specimens of the above. The first was from a single girl born in India, who had complained of pain in the vulva seven weeks previous to admission. She noticed small nodules at that time; these soon coalesced and caused her pain. She consulted a general practitioner, who commenced to remove the growth, but desisted owing to hæmorrhage. She came to Dr. Solomons, who found that the girl was a virgin, there was no vaginal discharge, and there was a spongy tumour of each labium, the one $4\frac{1}{2}$ inches by $2\frac{1}{4}$ inches, the other $4\frac{1}{2}$ inches by $1\frac{1}{2}$ inches. An examination was made for the filaria, and a Wassermann test made; both these tests were negative. There was no sign of gonorrhœa.

The second case was very similar, in that the girl was a virgin, with no vaginal discharge; the growth was much smaller, and had been increasing for seven years. He removed the labia majora in both cases. The patients had uneventful convalescences.

Sir WILLIAM SMYLY thought it would be difficult to exclude gonorrhœa as the cause of the papillary growth.

Dr. KIDD described a case of "spurious elephantiasis of the vulva" which had occurred in his practice.

The PRESIDENT said the specimens appeared to be rather typical of what was commonly known as gonorrhœal warts. He did not think that they were essentially due to the gonococcus, but that they were evidence of a chronic and continuous irritation from some infectious discharge. The photograph of the case would suggest that there was discharge, and that the condition was of much longer duration than given in the history.

Dr. SOLOMONS, in reply, said that the growths were papillomata, and that he had no reason for altering his opinion, which coincided with the pathological report that gonorrhœa was absent. The stains at the upper part of the thigh were due to the rubbing of the growth and also to the discharge from the mushroom-like tumour, not from vaginal discharge.

A UTERUS SHOWING A CHORION-EPITHELIOMA.

Dr. ALFRED SMITH said that Mrs. M., æt. 40, the mother of many children, was admitted to the gynecological department of St. Vincent's Hospital on September 20th, 1915. In the month of December, 1914, she had an abortion at the tenth week of pregnancy. She enjoyed good health up to the following February. She then noticed that her menstruation became heavy and irregular; hæmorrhages appeared. During March, April, and May, the irregular flows continued, becoming much heavier in July and August. The odour was most offensive. Bimanual examination under an anæsthetic showed a uterus enlarged to the size of four months' pregnancy; its consistence was soft and spongy. On washing out the uterus it was noticed that the bleeding became diminished, and no fragments of brain-like material came away. The tumour was obviously not an adeno-carcinoma.

A hysterectomy was performed. The patient left the hospital at the end of her third week.

Dr. T. T. O'FARRELL gave an account of his findings. The specimen measured 11 c.m. \times 10 c.m. \times 7 c.m. The dilated cavity of the uterus was occupied by a large spongy hæmorrhagic mass; on section the latter was seen to be directly connected to the uterine wall, but somewhat free towards the cervical end. Microscopical sections showed three more or less distinct zones: the outer muscular wall of the uterus, an inner laminated septic blood clot infiltrated with polymorphonuclear leucocytes, and an intermediate comparatively thin zone of tumour cells. The neoplastic zone showed two distinct elements, one consisting of rather darkly staining multinucleated protoplasmic masses, which in places appeared as large giant-cells, but in others were lengthened out into bands of varying thickness, which followed the line of blood clefts: syncytial protoplasm. The other element consisted of clear distinct cells, partly vacuolated, and containing rather faintly staining nuclei: Langhans' cells. The tumour substance was seen to invade the blood-vessels and muscular tissue. There was no decidua or glandular tissue present, the tumour directly impinging upon and infiltrating the muscular structure.

Sir WILLIAM SMYLY said that fifteen years ago he had exhibited a specimen of chorion-epithelioma at the Academy.

Dr. KIDD said that in both Professor Smith's case and in that alluded to by Sir William Smyly a comparatively long time seemed to have elapsed from the date of the abortion in one case and the removal of the vesicular mole in the other before operative measures were adopted.

ÆTIOLGY OF UTERINE PROLAPSE AND CYSTOCELE.

The PRESIDENT read a paper on this subject, in which he dealt with the normal supports of the pelvic viscera and considered the visceral layer of pelvic fascia to be the essential structure supported by the levator ani muscles. That laceration of the perinæum, even involving the levator ani, had no predisposing influence towards prolapse was certain, though it would allow cystocele to develop. Prolapse of the uterus was due to interruption of the fibres of the fascia which are attached to the vaginal fornices and the cervix uteri in what constituted the true parametric tissue, that cystocele is a hernia of the bladder through the pelvic fascia in front of the cervix, where the fascia passes between the vagina and the base of the bladder. These two conditions, though frequently confused, should be clearly differentiated for treatment. The viscera could be supported by the reunion of the fascia without interposition of the uterus, and the curative element in the present-day operations was the high amputation of the cervix, in covering the stump of which the pelvic fascia was caught in and united firmly to the uterus.

Dr. ALFRED SMITH said the importance of a torn levator ani muscle in the production of prolapse should not be lost sight of. If the levator ani, which was the muscle opposed in its action to the sphincter ani, and which dilated the latter, was torn, the sphincter could not dilate normally; a stool therefore met this muscle contracted, and, the pressure still continuing, the contents of the bowel bulged out the rectum into the lumen of the vagina, producing a rectocele. In doing this the posterior vaginal wall was drawn down, and it in turn pulled on the cervix. Cystocele occurred as a result of damage to the anterior wall during delivery. So great was the desire to save the perinæum in forceps and other difficult deliveries that the tissues beneath the symphysis were subjected to much dragging and pressure.

Dr. HASTINGS TWEEDY congratulated the President on the careful and painstaking manner in which he had demonstrated the importance of the endo-peritoneal tissue. His address had made it impossible to hold fast the old faith as to the influences which compelled the uterus to remain fixed in its ante-flexed position. He could believe no longer in the theory of abdominal pressure, either positive or negative, in the efficacy of the peritoneal folds—so-called ligaments—in the power of the pelvic triangles

or in the levator muscles as a means of sustaining the uterus. The point brought out by the President was that the one and only factor which counted in preventing prolapse of the uterus was this endo-peritoneal tissue, and whether it was derived from the parametrium or from the pelvic fascia seemed to be a matter of secondary importance.

Sir WILLIAM SMYLY believed that the successful treatment of this troublesome condition depended upon a clear knowledge of its anatomy, and especially upon the restoration of the connective tissue and fascial supports; but so far as his experience had carried him, he doubted the possibility of restoring the fascia which supported the bladder, and he would still resort, at any rate in women who had passed the menopause, to interposition of the uterus between the bladder and vagina, whilst in those who were likely to have more children he had found vaginal suspension a useful compromise. With regard to the uterus itself, he had no doubt that it was maintained in its position by the strong fibrous tissue at the base of the broad ligaments.

Dr. SOLOMONS said that the number of operations required to cure prolapse depended on the conditions present. He found it necessary to perform anterior colporrhaphy, with pushing up of the bladder, high circular amputation of the cervix, shortening of the utero-sacral ligaments, posterior colporrhaphy and perinæorrhaphy with some form of operation to cure the retroversion. It seemed to be difficult to determine whether these utero-sacral ligaments had any bearing in causing prolapse; it was certain, however, that they were strong bands which, when separated and brought in front of the uterus, acted as most efficient splints. He thought it would be well if operators who had opened the abdomen, after performing this operation, would say in what condition they found the utero-sacral ligaments. He would be glad to hear of a cure of a severe prolapse where the utero-sacral or lateral pelvic ligaments were not shortened. He did not consider the interposition operation should be done before the menopause.

Dr. GIBSON agreed with the President regarding the importance of the pelvic fascia in the support of the uterus and bladder. He believed, however, that when the fascia was ruptured and had stretched sufficiently to allow of prolapse, it could not be considered capable of preventing further prolapse when it was repaired, as the President suggested. He believed that the fascia would continue to stretch. He did not know of any cases of complete prolapse which had been cured by repairing the fascia. Neither did he believe that large cystoceles could always be cured by anterior colporrhaphy, even when the most extensive suturing of the tissues under the vaginal wall was carried out.

Sir ANDREW HORNE, Drs. ELLA WEBB, ASHE, and GOULDING also spoke.

The PRESIDENT replied.

WEST-LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JANUARY 14TH, 1916.

The President, Dr. LEONARD DOBSON, in the Chair.

THE following cases were shown:—

Dr. F. S. PALMER: (1) Functional monoplegia due to shock from bursting shell (soldier, æt. 24); (2) complete mutism and deafness due to shock from bursting shell (soldier, æt. 28), steady and uninterrupted progress under a system of re-education without hypnosis.

Major W. MCADAM ECCLES: (1) Abnormal venous channel in a male patient, dilatation of the anastomosis between the two superficial external pudic veins, with imperfect descent of the left testis. In reference to the case of *caput medusæ* shown by him at the clinical meeting held on November 5th, Major McAdam Eccles described the abnormal conditions, revealed by laparotomy, of some of the intra-abdominal veins. (2) and (3) Femoral hernia in a man (two cases).

Mr. O. L. ADDISON: Malignant glands of neck (male, æt. 60), almost total disappearance under massive doses of X-rays, heavily filtered, for a period of about three months, at the rate of two or three a week.

Dr. ARTHUR SAUNDERS: (1) Severe rickets and tuberculosis (male, æt. 5). (2) Subacute rheumatism, multiple nodules in occiput (temporal regions), knuckles, elbows, wrists, ankles, knees, flexor tendons of wrists, sternum, scapulæ, and vertebræ (male, æt. 11).

Mr. N. BISHOP HARMAN: (1) Case showing the effects of chronic blepharitis, said to have followed measles (male, æt. 36). This was described by Mr. Bishop Harman as being one of the worst cases of chronic blepharitis which he had ever seen. (2) Iridodialysis caused by air-gun injury (female, æt. 10).

Dr. GEORGE PERNET: (1) Ichthyosis of trunk and limbs (male, æt. 6). (2) Morphœa-scleroderma, outer sides of legs (female, æt. 14).

The following skiagrams were shown by Dr. REGINALD MORTON:—

Cases under the care of Dr. Arthur Saunders.—(1) Absorption and collapse of fourth and part of the fifth lumbar vertebræ, following para-typhoid fever (male, æt. 30). (2) Large aneurysm of the arch of the aorta, with protrusion of the sternum (two skiagrams).

Cases under the care of Mr. O. L. Addison.—(1) Myeloid sarcoma of upper ends of tibia and fibula female, æt. 43). (2) Old case of tuberculous disease of the hip-joint (male, æt. 26). (3) Large branched calculus in the pelvis, and a round calculus in the cortex of the left kidney (female, æt. 36).

Case under the care of Mr. H. S. Souttar.—Tuberculous disease of the hip-joint, with dislocation (male, æt. 8).

Case under the care of Mr. H. Tyrrell Gray.—Shrapnel bullet in side of neck, which entered in the region of the scapula of the opposite side (male, æt. 30).

Case under the care of Dr. E. D. McDougal.—Shattering of upper part of humerus by shrapnel, showing curious formation of new bone.

The President, Major W. McAdam Eccles, Dr. Arthur Saunders, Dr. Seymour Taylor, Dr. Harold H. Sanguinetti, Mr. O. L. Addison, Dr. S. D. Clippingdale, Dr. Rowland Pollock, and Dr. Reginald Morton took part in the discussion on the various cases.

LIVERPOOL MEDICAL INSTITUTION.

At the annual meeting of this Institution, held January 20th, 1916, the following office-bearers and members of Council were elected:—President, Charles J. Macalister; Vice-Presidents, R. J. Hamilton, W. J. Fleetwood, Frank H. Barendt and Walter T. Glegg; Treasurer, Llewellyn Morgan; General Secretary, Hubert Armstrong; Secretary of Ordinary Meetings, John Hay; Secretary of Ordinary Meetings (elect), John Owen; Secretary of Pathological Meetings, Frank H. Barendt; Secretary of Pathological Meetings (elect), J. Martin Beattie; Librarian and Editor of Journal, R. W. MacKenna; Council: Reginald T. Bailey, W. Allen Daley, F. M. Gardner Medwin, Thomas Guthrie, Walter C. Oram, Claude Rundle, Gerald Wallace, Mary Birrell Davies, Frank A. G. Jeans, George W. Pollard, Joseph A. Sanderson, A. Frank Walker.

MRS. EMILY ANN WIDDOP, of Harrogate, has left the residue of her estate of £11,264 in equal shares to the Harrogate Infirmary and the Bradford Infirmary.

THE Honorary Secretaries of King Edward's Hospital Fund for London have received at the Bank of England, from the League of Mercy its contribution for the year 1915 of £14,000.

A CONVALESCENTS' military hospital has been established at Pentrefynnon Hall, a beautifully-situated mansion on the Welsh estate of Lord Mostyn, near Holywell, and there are at present about a dozen wounded soldiers there.

SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

The Reappearance of Menstruation after Childbirth.

—Ehrenfest (*Amer. Jl. Obs.*, lxxii., 4) considers the question from observations and notes upon 209 patients in 309 births. There are numerous statistical tables, the general trend of which is to show that a debilitating influence exerted immediately by labour, and later by the loss of body fluids during lactation, with rare exceptions temporarily arrests ovulation. As soon as the disturbed equilibrium is restored, the ovary resumes its function of ovulation, and the first corpus luteum sends its specific hormone to the endometrium, and if this is normal a typical menstrual flow occurs; if it be hyperæmic from subinvolution there may be menorrhagia. If the uterus is atrophic it may require stimulation from one or more ovulations to start menstruation. The suspension of ovulation depends upon the general physical state of the woman, anything which debilitates delaying the return of menstruation, and consequently the amenorrhœic state generally lasts longer in the sick and weak woman, in the primigravida, whose labour as a rule is longer and more exhausting, and in the woman suckling a large child. In the majority of women equilibrium is regained before lactation ceases, and once menstruation reappears it generally continues regularly through lactation. F.

Premature Separation of the Normally Implanted Placenta.

—Williams (*Surg., Gyn. and Obs.*, xxi., 5) discusses the subject in the light of our knowledge up to 1911, and secondly from observations made since that date. Two cases are described, and the condition of the uteri which were removed considered. Both of the specimens showed a condition of infiltration of the muscle coats with blood and general engorgement of the tissues; the same conditions are described by numerous writers, being twenty cases collected from the past four years, and this is not exhaustive. The condition has been described as hæmorrhagic infraction of the uterus. There may be numerous small ruptures of the tissues on the surface of the uterus and broad ligaments; the broad ligaments, tubes and even ovaries may be involved. The condition is not confined to the concealed type of hæmorrhage. Endometritis, so-called, has no part in the ætiology of the condition. In severe cases it is associated with profound disorganisation of the uterine muscle. The causation is said to be probably dependent upon some as yet undifferentiated form of toxæmia, which may or may not be accompanied by albuminuria. As regards treatment, radicalism is strongly advocated. Nothing is stated to be required in the mild cases, while in the severe cases measures such as plugging tend to delay the adoption of radical measures. F.

Fate of Ovaries after Hysterectomy.—Vineburg (*Surg., Gyn. and Obs.*, xxi., 5) says the origin of ovarian internal secretion is still uncertain, although the follicles undergo various stages of development. It is not certain that the function of internal secretion continues undisturbed by the alteration in blood supply consequent upon the operation. It is still disputed as to the degree to which the climacteric syndrome is due to the removal of the ovaries or the injury to the pelvic nerves; the effect of retention of the ovaries in hysterectomies is only relative, and probably not 20 per cent. in favour of retention, and it appears as desirable after 45 years of age as before. Subsequent trouble in the ovaries does occur, and is probably much more frequent than appears from the literature. In view of the foregoing conclusions, the writer is of the opinion that the doubtful clinical advantages

obtained by retaining the ovaries are more than counterbalanced by the risks, and he would therefore not retain the ovaries in any case, unless enough lower uterine segment could be left to maintain menstruation. F.

Management of the Placental Stage of Labour.

—Polak (*Surg., Gyn. and Obs.*, xxi., 5), having studied 2,000 cases during the past year which were managed without control of the fundus, found that the placenta came away without any trouble or complication. The normal mechanism is that described by Schultz. There was no case of *post partum hæmorrhage* in the out-patients, and only three amongst 694 intern patients, including all the operative procedures. The placenta was retained five times; in three it was removed by Crede's method under æsthetic, being already detached; one was retained by a myoma, which acted as a ball valve in the lower uterine segment; the fifth was expressed after separation at the end of 96 hours. The manner of attending the third stage consists of turning the patient on her back, clamping the cord near the vulva, then waiting for signs of detachment, and then, but only then, handling the fundus and expressing the placenta when the uterus contracts. The retention of the placenta in the uterus for days is considered free from risk, provided it is either attached or completely detached, when the bleeding will be negligible. Sepsis is dependent upon the passage of the hand into the uterus through an infected vagina, and not upon the retention of the placenta. When the adhesion of the placenta is so great as to need actual digging out piecemeal of the placenta, hysterectomy should be our choice. F.

The Intrathecal Injection of Salvarsanised Serum.

—Spencer (*Birm. Med. Review*, December, 1915), records the cases of seven patients with tabes dorsalis, and five with sclerosis and interstitial cord lesions, who were treated with intrathecal injections of salvarsanised serum. The results were by no means uniform, but he has been able to draw from them the following conclusions:—The neo-salvarsan, or salvarsan injection, should be made by venepuncture to avoid the scar which results from the open operation. It is advantageous to use doubly distilled water for dissolving the drug, as the after effects of the injection when this water is used are very slight. Rigid asepsis in all manipulations is of paramount importance, as infection may be followed by disastrous consequences. A compound is probably formed in the blood between the neo-salvarsan and the serum proteins, which is strongly active against the specific organisms. The cerebro-spinal fluid rarely contains any arsenic after an intravenous injection of neo-salvarsan. Patients with symptoms of an irritative character such as lightning pains, or gastric crises, frequently suffer from an acute attack of these pains, which lasts from twelve to twenty-four hours after the injection, is easily controlled by morphia, and need cause no alarm to the physician, as the symptoms come on too soon after the injection to be due to sepsis. There is generally improvement or cure of the subjective symptoms, but no change was ever effected in the reflexes. The unsatisfactory results obtained in the patients with sclerosis and interstitial cord lesions are due to the fact that in these patients it is a matter of physical signs rather than symptoms, and therefore little improvement would be expected. Several injections are probably necessary to give permanent relief to the symptoms, or to bring the active progress of the disease to an end. The method is still on probation, but from a consideration of the pathology

of the tissues involved it seems the most rational one yet introduced for the treatment of syphilitic lesions of the nervous system. The method probably will never become very popular with the profession, owing to its difficulties, dangers, and tediousness, but it is worth trying when the other treatments have failed, on account of the miserable existence led by patients suffering from tabes with any of its irritative manifestations. Relief or cure of the subjective symptoms is here a distinct gain. From a consideration of the published cases, together with the cases seen by himself, Spencer believes that the method has not given as good results as might have been expected on purely theoretical grounds, owing possibly to the extreme sensitiveness of the central nervous system to any drug or toxin, thus preventing a sufficient amount of the drug from being introduced to be entirely effective on the spirochaetes. K.

Injection of Neo-Salvarsan into the Lateral Ventricle. Hammond and Sharpe (*Journ. Amer. Med. Assoc.*, December 18th, 1915), dissatisfied with the results obtained by the intradural administration of salvarsan, record their efforts to treat paresis by the injection of salvarsan directly into the lateral ventricle. In all, seven operations have been performed up to the present, and from the results of these the following conclusions are drawn:—In comparison with the deadly nature of the disease, the hazard of intradural treatment, by whatever method, is of little moment. On experimental and clinical grounds, both subdural and intraventricular methods are superior to the intraspinal route in the treatment of this disease. From an experimental and theoretical standpoint, the intraventricular method is superior to the subdural route, and it appears to be safer. The intraventricular method, with careful *technique* and a due regard for the anatomy of the brain and the delicate nature of the tissues one is invading, is, the writers believe, practically free from danger. If the freedom from unfavourable symptoms so far achieved in intraventricular injection can be maintained, it will be imperative so to treat paretics in the earliest stages, with a greater chance of improvement, and perhaps permanent arrest of symptoms. K.

Radium in Parotid Tumour.—Weil (*Journ. Amer. Med. Assoc.*, December 18th, 1915), has treated a parotid tumour of seven years' duration, presenting certain characteristic pathological features, for a period of six weeks, by the insertion of radium into the tumour. The tumour disappeared, and after an interval of almost two years presents no recurrence. K.

OBITUARY.

DR. W. F. SMARTT, L.R.C.S.I., L.A.H.,
BATHFORD.

THE death is announced of Dr. W. F. Smartt, of Radnor Lodge, Bathford. Six weeks ago he met with a very serious accident in Norfolk. He had given up his practice temporarily in order to do war work—he was a captain in the Royal Army Medical Corps and was stationed with a unit in Norfolk. One night, driving in a pony trap, he was run into by a heavy Army lorry, which smashed the trap to pieces and inflicted grave injuries upon Dr. Smartt. He was removed at once to a Red Cross Hospital, where he died.

Dr. William Francis Smartt, who was 54 years of age and unmarried, was a Licentiate of the Royal College of Surgeons, Ireland (1882), and a Licentiate of the Apothecaries' Hall, Dublin, spent some years in the Colonial medical service, and was Government Medical Officer for British Guiana. He went to Bathford some six or seven years ago and commenced practice.

DR. HERBERT WILLIAMS, M.D., D.P.H.,
LONDON.

THE death occurred on January 16th of Dr. Herbert Williams, medical officer of health for the Port of

London. Following an operation last year, Dr. Williams recently underwent another for appendicitis, and succumbed finally to heart failure in his 53rd year.

Dr. Williams was known alike for his genial disposition and his scientific attainments. He was educated at London University, and received his medical training at St. Bartholomew's Hospital. He graduated M.D. London in 1890, and took the Cambridge Diploma of Public Health in 1893. In 1892 he entered the service of the City Corporation in the capacity of assistant medical officer of the Port of London Sanitary Authority, and nine years later he succeeded Dr. Collingridge as medical officer, a position which he held to the end of his life with great distinction to himself and benefit to the inhabitants of London. Dr. Williams was an enthusiastic patron of outdoor sports, and was a good golfer and oarsman. Some years ago he was a major in the 1st Kent Royal Garrison Artillery Volunteers, and during the South African War acted as adjutant to the corps.

REVIEWS OF BOOKS.

TWO USEFUL WAR BOOKS.

Two books, especially written for the purposes of the war, have just been issued, which can scarcely fail to supply a want. One is on "Bandaging" (a) and the other on "The Selection of the Recruit" (b). Each has a value of its own, for each displays an intimate knowledge of the special requirements which this war has evoked. In Mr. Fitzwilliams' work, besides the ordinary methods of bandaging in common use, other methods, but little required in civil practice, are fully described and illustrated, such as the complexities of wounds demand. In this regard an important section is that devoted to the description and uses of the triangular bandage, the scope and the utility of which in military practice is admittedly extensive. The book is essentially adapted for the information and guidance of orderlies, nurses, and others engaged in attending to wounded men. A feature of the work is the profuseness of its illustrations. It is of interest to note that the drawings were done by a Hungarian prisoner of war in Malta at the author's suggestion. The frontispiece is a caricature of the typical "Little Willie" supporting himself upon two massive crutches. The left leg from the knee downwards is thickly covered with wadding, secured by a spiral bandage; the forward position of the limb suggests the first movement of the "goose step," but further exhibition of that Teutonic imbecility is restrained by a sling extending from the foot to the back of the neck. An iron cross dangles conspicuously from a military collar. Possibly this Hungarian artist intended other impressions to be conveyed by this drawing which do not appear upon the surface. We have no hesitation in saying that this is the best book on bandaging which has come under our notice.

In Captain Begg's book the recruiting problem is discussed from a scientific standpoint. Among other things it contains much valuable statistical information dealing with anthropometrical matters. The first four chapters are devoted to the consideration of the recruit from the aspect of the various factors of age, growth, development, the causes of rejection, etc. Allusion among the latter is made to diseases of the heart, which formed the highest ratio of rejections in 1909. The author, however, does not mention cigarette smoking in this connection as the cause of cardiac disturbance, which in Army reports is referred to as materially affecting the fitness of a recruit for service. The procedure of examining recruits is next fully described and explained. The last part of the work is mainly statistical. Apart from their technical value, the author's pages cannot fail to be of interest to those whose hobby is to claim that we are a degenerating race. The surmises of these pessimists

(a) "A Practical Manual of Bandaging." By Duncan C. L. Fitzwilliams, F.R.C.S., Capt., R.A.M.C.T. London: Bailliere, Tindall and Cox. 1916.

(b) "The Selection of the Recruit." By Captain S. T. Begg, M.B., M.D., R.A.M.C. London: Bailliere, Tindall and Cox. 1915.

MEDICAL NEWS IN BRIEF

City Dispensary.

THE Lord Mayor, presiding at the 127th annual meeting of the City Dispensary, held on January 19th at the Dispensary, College Street, E.C., said he knew of no institution that did better work at a less expenditure of money than that dispensary. During the year there had been 15,793 attendances on the sick poor, which was a sufficient proof of the valuable work being done.

School Medical Inspection.

AT a Gloucestershire County Council meeting, Mr. F. A. Hyett, chairman of the Education Committee, said the Finance Committee would present at the next meeting provisional estimates in which no sum would be provided for the continuance of medical inspection, but only for a limited scheme of dental treatment. He had thought it wise to ascertain what would be the view of the Board of Education if medical inspection were discontinued in its entirety, and what would be the grant for the dental treatment. The reply had surprised him, for the Board said that if medical inspection were discontinued, not only would they make no grant for dental treatment, but that the grant for the ordinary work of elementary education in the schools would be in danger of being diminished. The Board also told them that they were the only authority in the whole of England who proposed to discontinue medical inspection.

Anonymous Gift of £10,500 to Cardiff Hospital.

AN anonymous gift of 10,000 guineas to the King Edward VII. Hospital, Cardiff, towards the cost of new extensions was announced by the hospital authorities on January 17th.

Hospital Saturday Fund's Brine Baths Home.

TO the convalescent homes and sanatoria which they now own the Birmingham Hospital Saturday Fund Committee are shortly to add a brine baths home at Droitwich. Lately a specially favourable opportunity has presented itself for the acquisition of a suitable building at Droitwich, and it is probable that within a very short time the fund will have acquired a home with the accommodation for twenty-five patients, which was specially erected by a doctor for the reception of persons requiring treatment for rheumatism.

Royal College of Surgeons.

THE Council of the Royal College of Surgeons have voted the sum of 50 guineas to the joint fund of the British Red Cross Society and the Order of St. John of Jerusalem. The Council have appointed Sir G. H. Makins, who is serving as consulting surgeon to the Expeditionary Forces in France, to be the next Hunterian Orator of the College.

Carnarvon Hospital for Wounded.

THE Carnarvon Board of Guardians, having decided to place the Ervri Infirmary at the disposal of the War Office for the reception of convalescent troops, a special meeting of the Board took place on January 15th, when final arrangements were agreed upon. These will involve removing thirty-one patients now at the infirmary to the old workhouse hospital near by and fitting up the infirmary with thirty more beds and other requisites sufficient to accommodate a total of sixty patients. Additional nurses are also to be engaged.

£8,400 for Motor Ambulances.

AT a meeting of the Federation of Master Cotton Spinners at Manchester, on 21st January, a scheme was approved under which each of the fourteen districts into which the federation is divided contribute £600 for the purchase of an ambulance car, making fourteen cars in all, at a cost of £8,400. The money will pay for the cars and twelve months' running expenses.

are mostly based upon the recruiting statistical returns of the Army reports. It is evident, however, that the standardisation of the race cannot be gauged by the changing conditions introduced from year to year by the War Office for recruiting purposes. This book is an indispensable guide, in our opinion, for all engaged in the medical examination of recruits.

PRINCIPLES OF GENERAL PHYSIOLOGY. (a)

IN a delightfully written preface Professor Bayliss tells us that he has spent much time in the extraction from books and original papers, many of them not biological, of material of fundamental importance in the proper treatment of physiological processes. The result of this labour is offered to others in the handsome volume before us. The work deals with "abstract" or "general" physiology rather than the "applied" physiology required by the agricultural, medical, or veterinary student. The anticipated criticism, "What is the good of it all?" is very fully met. We are reminded that the practical value of pure abstract laboratory work is often very great. The electrical waves of Hertz were referred to in the first edition of Karl Pearson's "Grammar of Science" as of no practical application, but before the second edition appeared they were used for wireless telegraphy.

The opening chapter deals with protoplasm, and in some respects it may come as a shock to the enthusiastic microscopist to learn what a vast possibility of error centres round the use of histological reagents and microscopic vision. Subsequent chapters deal with such subjects as energetics, surface action and the colloidal state. Much of all this is exceedingly technical and several pages require a knowledge of higher mathematics for a complete understanding of them; but the author's style is so simple and graceful that the non-technical reader can easily follow all the arguments. The subject-matter of each chapter is recapitulated in a most useful summary.

The chapters on nutrition, digestion, reflex action, respiration, circulation and hormones, drugs and toxins are brimful of interest to the medical reader. In some instances he will wish that the author had added more of the practical applications, but on the other hand he will often find himself engrossed in abstruse principles in which perhaps he little suspected that he had any interest whatever.

The book is a monument of industry. There is an extensive and well-digested bibliography. There are 250 illustrations of excellent quality. They include 27 portraits of men whose researches have specially advanced knowledge of scientific subjects, and this gallery gives an added interest to an admirable book. There are also a few reproductions of great historical interest, including a copy of Leonardo da Vinci's drawing and part of his description of the vascular system. The book has a special interest to the biologist and physiologist, but we can heartily recommend it as a most interesting study to the broad-minded practitioner and as a corrective to the narrow.

DR. R. DE LA POER BERESFORD, Medical Officer for Oswestry and district, who has been an M.D. for 51 years, has now taken the degree of Master of Hygiene at Liverpool University.

DR. CARTER, who for the past eight years has been a member of the honorary staff of the Wolverhampton General Hospital as an assistant physician, has now been appointed an honorary physician.

DR. EDMUND THOMAS, Bridgend, is the Medical Officer of the St. John auxiliary hospital which has been established at the Southerndown "Rest." Dr. Thomas has done a great deal of work on behalf of the St. John Ambulance Association in Glamorgan.

Serbia's Need

WE are asked to give publicity to the following:—
 "To avoid any possibility of confusion in the administration of contributions intended for the benefit of the distressed Serbian population, the Serbian Legation requests that subscriptions intended for the Serbian Relief Fund, of which H.M. the Queen is Patroness, should be sent to the Earl of Desart, K.C.B., at the offices of the fund, 5, Cromwell Road, South Kensington, S.W. The Serbian Legation will continue to receive subscriptions for the following Serbian Funds:—(1) The Archbishop of Belgrade's Fund for the families of the killed and wounded soldiers. (2) The Society of the Serbian Red Cross. (3) The Parliamentary Commission for the Refugees. (4) The Society of St. Helena for the orphans whose parents have been killed in the war. All contributions addressed to the Serbian Legation (195, Queen's Gate, London, S.W.) for these funds will be gratefully received and acknowledged.

Shortage in Medicine Bottles.

HOW a parent's suspicions were awakened because a doctor took away a medicine phial from which doses had been given a dying child, was revealed at Westminster Coroner's Court.

It was the shortage of glass bottles that led the doctor to take away the phial.

The Coroner said that the medicine had been carefully prepared, after examining the prescription and the phial.

Dr. Trevor, pathologist, added that at the museum at St. George's Hospital they could not get bottles except at a colossal cost.

The Coroner said he supposed the medicine bottles used to come from Germany or Austria, which would account for the difficulty in getting them.

Economy in Food.

DR. ROBT. HUTCHISON, lecturing at the Institute of Hygiene on waste in foods, said that we were spending annually more than £600,000,000 on food, and we might easily save 10 per cent. of that sum without any ill-effect on health. A large section of the community could save a good deal by eating less of everything all round, but he excepted those who work hard with their hands and growing children.

Worcester Doctors and Eligible Medical Men.

THE honorary medical staff of Worcester Infirmary have informed the committee of that institution that they decline to work with any man of military age appointed temporarily to take the place of a colleague who has joined the army.

Influenza in the United States.

ONE of the most serious epidemics of influenza ever known in the United States is described in the report of the Public Health Service. It was widely prevalent in New York, Chicago, Philadelphia, Boston, San Francisco, Seattle, Cleveland, and Detroit, the two latter cities having probably 100,000 cases.

Medical Recruiting in Ireland.

THE Secretary to the Department of Recruiting for Ireland has issued the following statement to the Press:—

Following on representations which have been made to him by the Irish Medical War Committee, the Lord Lieutenant, as Director-General of Recruiting for Ireland, has sanctioned the recognition of that Committee as the official channel of recruiting for the medical profession in Ireland.

The Committee have undertaken to give every possible assistance to the military authorities in the provision of medical officers for the army.

With this object in view, they are prepared to facilitate the release of younger members of the profession by endeavouring to provide acceptable substitutes, and if so desired, by helping to reorganise the medical service.

Members of the medical profession who wish to

apply for commissions in the Army Medical Service are accordingly recommended to write, in the first instance, to the Hon. Secretary of the Committee, c.o. the British Medical Association, 16 South Frederick Street, Dublin.

Radiograph Car Fund.

FIELD-MARSHAL LORD GRENFELL will preside at a meeting at the Queen's Hall on January 27th, at which addresses in support of the Fund for Radiograph Cars at the Front will be delivered by Sir James Mackenzie Davidson, M.B., and the Hon. Arthur Stanley. The band of the Grenadier Guards will be present. There will be a procession of women workers in uniform, and Miss Muriel Foster will sing. A demonstration of X-ray machines will be given.

Health Officials and Alcohol.

THE following resolution was adopted by the medical officers of health of Nova Scotia at a conference: "Whereas it has been absolutely proven that alcohol has a pernicious and injurious effect on the public health of our country, in that it lowers the resistance of the individual to disease, thereby disposing to tuberculosis and other infectious diseases; and whereas it is one of the chief contributing factors to poverty, misery and crime; therefore we, as health officers of the Province of Nova Scotia, place ourselves on record as opposed to its use as a beverage, and strongly recommend its use only upon medical prescription."

Nursing in Derbyshire.

IN the annual report of the Chesterfield District Medical Association, it is stated that as the result of a private meeting addressed by the Duchess of Devonshire at Chesterfield, a movement has been inaugurated to transfer the headquarters of the Derby Nursing Association to Chesterfield. The object is to organise nursing in the north-eastern portion of Derbyshire upon more effective lines.

Supply of Doctors for the Army.

IN the House of Commons last week, Mr. Tennant, in reply to Mr. Lynch, said that, thanks to the patriotism of the medical profession, there was no present anxiety regarding the supply of doctors for the Army, and the Central Medical War Committee, with which the Director-General of the Army Medical Service was in touch, had carefully guarded the interests of the civil population, the claims of which had not been, and would not be, disregarded.

Society of Apothecaries of London.

THE following candidates having passed the necessary examinations, have been awarded the L.S.A. Diploma of the Society, entitling them to practise Medicine, Surgery, and Midwifery:—C. B. De Forest, D. M. Hunt, G. L. T. Lawlor, I. H. Lloyd, T. C. Russell, J. G. T. Thomas and A. J. A. Wilson.

Royal Colleges of Physicians and Surgeons, Edinburgh, and the Royal Faculty of Glasgow.

THE Examinations of the Conjoint Board for the triple qualification were concluded at Edinburgh on the 21st inst., with the following results:—

First Examination.—The following candidates passed the First Examination:—Alice Fung-a-Ling, Alexander F. Caddell, Gwilym ap Vychan Jones, William Gibb, and David Gilmour.

Physics.—Michael Quinlivan, Lizzie R. Clark, and Norman H. Mackay.

Biology.—Michael J. Quinlivan, Robert B. Forgan, William H. Kerr, and Mayberry H. Carleton.

Second Examination.—The following candidates passed the Second Examination:—Eliza J. Stuart, Thomas T. Reade, Cyril T. Casking, Andrew F. Brighmen, William B. Watson, Patabedimuhandirange M. Fernando, and George P. de Silva.

Anatomy.—Andrew B. Macdonald.

Physiology.—John K. Steel, Donald Mackay, Leo H. Peries, and David Levenstein.

Third Examination.—The following candidates

passed the Third Examination:—Spearman C. Swinburne, James H. Brown, Robert McLaren, William B. Lawson, Robert G. Battersby, Benjamin Ajaji-Young and Thomas Jackson.

Pathology.—Edward G. Jones.

Materia Medica.—Alexander B. Black, Christopher R. C. Moon and Mohammed Talaat.

Final Examination.—The following candidates, having passed the Final Examination, were admitted L.R.C.P.E., L.R.C.S.E., L.R.F.P. and S.G.:—Thomas C. MacGowan, Claud A. Slaughter, Theodore C. van Derzeil, Alexander W. McGregor, Charles K. Carroll, George L. Pillans, L.D.S., William L. Paterson, David S. Taylor, David S. Luther, and Donald S. Graham.

Medicine.—Thomas Jackson and John Bygott.

Surgery.—Robert C. Wilson Spence, Bertram C. Haller, and John E. Kitchen.

Midwifery.—Andrew Smith, junr., and John Ross.

Medical Jurisprudence.—Harry Ellison, James W. Cordon, Stanley W. Hoyland, Thomas Hardie, James S. Durward, Alexander Morrison, James V. R. Rohan, Gilbert Ll. Stanley, James Y. McLean, Edward M. L. Morgan, Reginald J. T. Malcolm-Gasper, William B. Lawson, and John G. McK. Macaulay.

MEDICAL WAR ITEMS.

HIS MAJESTY THE KING has been graciously pleased to approve of the appointment of the undermentioned officer to be Companion of the Distinguished Service Order, in recognition of his gallantry and devotion to duty in the field:—

Captain Alexander Findlater, M.D., 1st London Mounted Brigade Field Ambulance, R.A.M.C. (T.F.), for conspicuous gallantry and devotion to duty on several occasions, notably on September 20th, 1915, at Chocolate Hill, Gallipoli Peninsula. He crossed over 200 yards of open ground under very heavy shell fire to render aid to two wounded men. He saved the life of one, but the other was beyond help.

His Majesty the King has been graciously pleased to confer the Military Cross on the undermentioned officer, in recognition of his gallantry and devotion to duty in the field:—

Temp. Lieutenant John Wesley Gilbert, R.A.M.C. (attached 9th Brigade, R.G.A.), for conspicuous gallantry and devotion to duty near Ypres on December 29th, 1915. After three attempts he succeeded in entering a farm, which was being heavily shelled with gas and other shells, and rendered valuable assistance to the wounded infantry who were billeted there.

A SUPPLEMENT to the *London Gazette* issued on 22nd January contains the following:—

Distinguished Service Cross.—The King has been graciously pleased to give orders for the award of the Distinguished Service Cross to the undermentioned officer in recognition of his services during the advance on Kut-el-Amara on the 27th and 28th September, 1915: Surgeon Dermot Loughlin, M.B., R.N. Surgeon Loughlin attended the wounded on board the *Comet* under a heavy fire at cose quarters on the night of the 28th September.

THE Supplement to the *London Gazette* contains the announcement that the following is mentioned for his services with the British Naval Mission in Serbia:—

Temporary Surgeon Edward Rowland Alworth Merewether, R.N.

COLONEL E. O. WIGHT, Assistant Director of Medical Services, who was killed in Flanders on December 19, was born on May 29, 1858. He was the youngest son of the late Dr. Robert Wight, F.R.S., East India Company's Service. Colonel Wight entered the Service in February, 1882, reached the substantive rank of lieutenant-colonel in the R.A.M.C. in 1902, and retired in March, 1907. On the formation of the Territorial Force he accepted the post of

D.A.D.M.S., Home Counties Division, in which capacity he was still employed when war broke out. On mobilisation of the Home Counties Division he went with it to Maidstone, Canterbury, and Windsor. In April last he was offered the post of A.D.M.S., 49th Division, which had been ordered abroad, and he was serving in this capacity at the time of his death. Before the present war Colonel Wight saw service in the Lushai Expedition, Burma, in 1802, and was decorated with the medal with clasps. He also had the Royal Humane Society's bronze medal and two vellum testimonials from the same source, for saving lives from drowning on three different occasions. He was L.R.C.P. Edin. in 1881, M.R.C.S. Eng. in 1881, and D.P.H., R.C.P.S. Lond. 1902, and was a Fellow of the Royal Institute of Public Health. He was killed by a shell whilst assisting to extricate some of his motor ambulances from a dangerous position. One of his senior officers in writing of him says:—"He was a man who had become proverbial as one who had no fear; one of the most gallant gentlemen I have ever met, and who was an object of devotion and reverence to his own officers and men, ever setting them a fine example of duty before all; one who was beloved and respected by all ranks. All mourn him, as they have not only lost a true friend, but also a wise director and an original and clever organiser of things for their good, one whose whole heart and soul was in his work."

Captain John Victor Livingstone Grant, M.B., Royal Army Medical Corps, attached to the Warwickshire Battery (T.F.) Royal Horse Artillery, wounded while with the Army in France, was previously in practice at Edinburgh, and took his degree in the University of that city four years ago. He was formerly House Surgeon at the Victoria Hospital, Burnley. Capt. Grant joined the Army Medical Corps in September last year.

Capt. Russell Ernest Walker, M.B., Royal Army Medical Corps, attached to the 2nd Battalion Durham Light Infantry, who has been wounded while performing his medical duties in the North of France, practised in Peterborough. He qualified M.B., Ch.B. at Edinburgh in 1912.

Lieut. Matthew Arnold Swan, M.B., Royal Army Medical Corps, attached to the Royal Field Artillery, who has been wounded while performing his medical duties in the North of France, practised in North Shields before the war. He took his degrees in Edinburgh in 1901.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

NOTICE. CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s; post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces. Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are requested kindly to send their communications, if resident in England or the Colonies, to the Editor, at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, 29, Nassau Street, in order to save time in forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

MEDICAL SICKNESS, ANNUITY AND LIFE ASSURANCE FRIENDLY SOCIETY.

We are asked to announce that the thirty-third annual general meeting of the members of the above Society will be held on March 25th, at 4.30 p.m., at the Society's Offices, 300, High Holborn, London. Nominations for the election of members to the Committee must be received in writing at the Society's offices one month before the date of the meeting.

J. H. (Hampstead).—Is thanked, but his communication is hardly suitable for our columns.

M.D., F.R.C.S.—The price of the drug, so largely increased during the war, is purely a trade matter. It is probably genuinely based upon the present exigencies of supply. But beyond that supposition we know not whether chemists are taking advantage of the war to increase their profits.

P. K. T. (Leeds).—The matter is discussed in the last annual report of the Registrar General.

JUVENILE CRIME.

MR. SYDNEY EDRIDGE, magistrates' clerk at Croydon, reports that an increase of crime among juveniles synchronises with the conversion of day schools into hospitals and consequent placing of scholars on half-time; also owing to so many men being with the colours there is an absence from the homes of wholesome influence.

KLAXON (Brixton, S.W.).—Five deaths attributable to vehicles in the street occurred in London during the week ended January 15th.

MORE SPIRITS DRUNK.

DURING November, 919,000 proof gallons of spirits were cleared in London, as compared with 810,000 gallons in November, 1914. The total for the eleven months ended November 3rd, 1915, was 8,272,000 gallons.

TUNOR (Mansfield).—We observe that, as a result of the first week's operations under the Order making compulsory the notification of measles as an infectious disease, no fewer than 271 cases were reported in Nottingham.

THE FRENCH MEDICAL PROFESSION AND THE WAR.

In an address before the Paris Surgical Society, Professor Tuffier said that of the 14,000 surgeons in the army, 6,500 were at the front. Of these, 93 had been killed, 260 wounded and 441 missing; 135 had been mentioned in orders for gallant conduct on the battlefield.

Meetings of the Societies, Lectures, &c.

THURSDAY, JANUARY 27TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF NEUROLOGY) 1, Wimpole Street, W.,—8.30 p.m.: The Special Discussion on the "Functional Neuroses caused by Shell Shock without Visible Signs of Injury" will be continued. The chair will be taken by the President (Dr. James Taylor), and Dr. Batten, Dr. Farquhar Buzzard, Dr. J. S. Collier, Dr. E. G. Feanersides, Dr. Wilfred Harris, and Dr. Campbell Thomson will speak.

Members wishing to take part in the discussion should communicate at once with Dr. Hinds Howell, 145, Harley Street, W.

FRIDAY, JANUARY 28TH.

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISEASES OF CHILDREN) (1, Wimpole Street, W.),—4.30 p.m.: Cases: Mr. Sydney Stephenson: Dyspituitarism in a Girl of 15 years. Dr. J. D. Rolleston: Transient Hemiplegia in Diphtheria with Lesions of the Finger-nails. Dr. J. L. Bunch: Papillomatous Growth in a Scar. Dr. Eric Pritchard: (?) Cerebral Tumour in a Child. Dr. C. O. Hawthorne: Double Optic Neuritis. Specimens: Dr. E. C. Williams: Heart showing infiltration by Large Round-celled Sarcoma. Miss M. B. Stogden and Miss J. H. Younger (introduced by Dr. Eric Pritchard): Congenital Double Hydro-ureter. Short Paper: Dr. J. Porter Parkinson: Nephritis without Albuminuria.

WEDNESDAY, FEBRUARY 2ND.

HUNTERIAN SOCIETY (Guy's Hospital, London Bridge, S.E.).—4 p.m.: Clinical Afternoon. Cases of Clinical Interest will be shown by, or for, members of the staff of Guy's Hospital.

Vacancies.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Barrow-in-Furness (Lancaster). Staplehurst (Kent).

Royal Albert Edward Infirmary and Dispensary, Wigan.—A Lady House Surgeon, Salary £150 per annum, with board, apartments, and washing. Applications to L. E. Mapei, Acting Secretary.

Birmingham General Dispensary.—Resident Medical Officer. Salary £250 per annum, with furnished apartments, fire, lights, and attendance. Applications to Ernest W. Forrest, Secretary, 32, Union Street.

Borough Hospital, Birkenhead.—Junior House Surgeon, Salary £180 per annum, with board and laundry. Applications to the Secretary.

North Ormesby Hospital, Middlesbrough.—House Surgeon. Salary £150 per annum, with board, residence, and laundry. Applications to Arthur Williams, Secretary.

Bury Infirmary.—Senior House Surgeon. Salary £250 per annum, with board, residence, and washing. Applications to the Honorary Secretary, Infirmary, Bury, Lancs.

The Victoria Hospital for Children, Tite Street, Chelsea, S.W.—Senior Resident Medical Officer. Salary £250 per annum, with board, lodging, and washing. Applications to the Secretary.

Warneford General Hospital, Leamington Spa.—Resident Medical Officer. Salary £150 per annum, with board, residence, and laundry. Applications to Fred Smith, House Governor.

Appointments.

BLAIR, C. E., M.B., Resident Physician at the Edinburgh Royal Infirmary.

BURNET, J., M.D. Edin., Certifying Surgeon under the Factory and Workshop Acts for the Edinburgh, South District of the county of Edinburgh.

FERGUSON, H. F., M.B., Ch.B. Edin., Resident Physician at the Edinburgh Royal Infirmary.

MALCOLM SMITH, G. L., Clinical Assistant at the Edinburgh Royal Infirmary.

PURNELL CHARLOTTE, M.B., B.S. Durh., Senior House Surgeon at the Bolton Infirmary.

SLOAN, SAMUEL, M.D. Glas., Examiner in Midwifery and Diseases of Women to the University of Glasgow.

Births.

ANDERSON.—On January 18th, at Newholme, Pitlochry, the wife of John Anderson, M.B., C.M., Edinburgh, of a daughter.

BOYS STONES.—On January 18th, at Knutsford, Cheshire, the wife of W. Boys Stones, B.C., etc., of a son.

CANNEY.—On January 17th, at 60, St. Andrew's Street, Cambridge, the wife of J. R. Campbell Canney, M.D., B.C., Capt., R.A.M.C., T.F., of a son (prematurely).

HENSON.—On January 19th, at Normanton, Yorks, the wife of P. H. Henson (M.B., B.S. Lond.), of a son.

LEGG.—On January 18th, at 71, Lessingham Avenue, Tooting Graveney, the wife of Cyrus Legg, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

MENNEL.—On January 21, at 1, Royal Crescent, W., to Dr. and Mrs. James Beaver Menell—a son.

POPE.—On January 17th, at 54, Eversfield Place, St. Leonards-on-Sea, the wife of Charles A. W. Pope, M.B., Lieut. R.A.M.C., of a daughter.

Marriages.

BROOKES—POWELL-JONES.—On January 19th, at the Parish Church, Hampstead, Lt. Arthur Stanley Brookes, R.A.M.C., only son of Mr. and Mrs. Albert D. Brookes, of 29, Apsley Road, Clifton, Bristol, to Gertrude Mabel Powell-Jones, daughter of Mrs. Powell-Jones, of Durlay, The Avenue, Surbiton, and the late Morgan Powell-Jones, J.P., of Pwll Court, Crickhowell, Breconshire.

CLOUGH—TOPHAM.—On January 18th, at Halifax, Yorks, James Arthur Clough, M.B. (Lond.), L.S.A., West African Medical Staff, Deputy Principal Medical Officer, Nigeria, to Dorothy Elizabeth, only daughter of the late Dr. A. S. Topham and Mrs. Topham, of Braemar, Huddersfield Road, Halifax.

CUMMINS—MELVILLE.—On January 15th, at All Saints, Colville Gardens, Staff Surgeon Arthur D. C. Cummins, R.N., H.M.S. Orion, son of Walter Cummins, Esq., of Cork, Ireland, to Sheelah, younger daughter of the late Samuel and of Mrs. Melville, of 41, Colville Gardens, W.

HODGSON—LAIDLER.—On January 18th, at St. Jude's Church, Bradford, Capt. Gordon A. Hodgson, R.A.M.C., son of the late Edwin Hodgson, Manningham, to Marion Untbank, eldest daughter of Francis Laidler, Esq., of Marlborough Road, Bradford.

LOYD—WATHEN.—On January 19th, at St. Michael and All Angels, Kingstone, William Frank Lloyd, Lieut., R.A.M.C., eldest son of Mr. and Mrs. W. Garrold Lloyd, of Oaklands, Hereford, to Margaret Wathen, younger daughter of the late T. W. Wathen, of Bridge Court, Herefordshire.

MILLIGAN—MOORE.—On January 15th, at St. Ann's, Highbury, E. T. Campbell Milligan, Capt., R.A.M.C., only son of Mrs. and the late Mr. E. Milligan, Billarat, Victoria, Australia, to Jessie Sarah, younger daughter of the late Philip Moore and Mrs. Moore, of Moorlands, Hay, New South Wales.

WATKIN—RICHARDS.—On January 18th, at All Saints, Margaret Street, W., Arthur Christopher Watkin, Capt., R.A.M.C. (T.F.), to Annie Eileen Wynn, eldest daughter of the Rev. W. L. and Mrs. Richards, of Llangniew Rectory, Welshpool.

Deaths.

MACILWAINE.—On January 19th, at Clevedon, Somerset, Sydney Wilson Macilwaine, M.R.C.S., L.R.C.P. (late of Redhill), aged 61.

PRICHARD.—On January 11th, at 3, Malden Road, Watford, of pneumonia, Arthur Heath Prichard, Surgeon, R.N., retired, aged 39 years.

WILLIAMS.—On January 16th, 1916, Herbert Williams, M.D. Lond., of 7, Ulundi Road, Blackheath, Medical Officer of Health for the Port of London.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

Wounded and After. ON the question of the after-treatment of wounded and otherwise invalided soldiers, both Professor Sherrington and Sir Frederick Milner have recently had some pertinent remarks to make. It seems that once a man leaves hospital he is officially regarded as cured, and is at once treated as though he were fit for duty; not light duty at home, but strenuous duty at the front. The War Office is apparently unable to realise that although a man be healed of his wounds, his general condition may be such as altogether to unfit him for serious military work. The result is that such men are sent out to the front, only to break down again; thus becoming a source of anxiety to the medical officers and a nuisance to the military. As Professor Sherrington puts it, "The State is burdening beyond all limits of endurance backs in many cases already broken." How is it that a due period of convalescence is not insisted upon in these cases? On grounds of economy alone, to say nothing of grounds of humanity, such a course is the only proper one. It is a long time since 'bus companies and others found that it did not pay to treat their animals badly.

A Case with Comments. SIR FREDERICK MILNER tells the story of a man who was invalided home from the trenches (with what, does not appear) and was sent to hospital. When discharged from hospital he still felt ill, and begged the authorities to release him. He was a skilled artisan, and his late employer, who wanted him for munition work, backed the petition. It was all to no purpose; the plea of invalidism and the support of the former employer were peremptorily swept aside, and the man was ordered to Egypt, where he now lies in hospital. As Sir Frederick Milner very properly points out, not only are this man's services as a fighting man lost to the country, and his services as a munition worker at home, but he now becomes a burden on the taxpayer for an indefinite period. I cannot help feeling that the medical part in this drama must have been rather unsympathetically played. The R.A.M.C. officers are naturally on the look-out for malingerers, and properly give them short shrift, but there is a

wide difference between malingering and tardy convalescence. Moreover, it is right that the quality of a man's nervous system should be taken into account. Many of those now under arms are unaccustomed to a military atmosphere, and dislike fighting; they are soldiers only from a sense of duty, and there ought to be some sympathetic discrimination between those who are "thin red 'eroes" from choice, and those who have become so from patriotic necessity. The position of the medical man is, however, a difficult one, and he has probably learnt by experience that it is better to err on the side of severity. It might, however, be well to remind him that by no means all of those who to-day serve in the ranks enjoy the robustious nervous system of the ordinary Tommy.

Professor Sherrington. PROF. CHARLES SCOTT SHERRINGTON, who has held the Waynflete Chair of Physiology at Oxford since 1913, is one of the most brilliant of the coterie of British physiologists who have recently won so much fame in the world of science. The value of his contributions to the study of the brain and nervous system has been officially recognised in all civilised countries. He is a graduate of Cambridge, where he took his M.B. in 1885 and his M.D. in 1892 (Caius). He is now a F.R.S. and LL.D. of several universities. He was at one time Lecturer on Physiology at St. Thomas's Hospital, and later on Professor of Physiology at the University of Liverpool: He is by no means a mere laboratory man, unacquainted with public affairs, for he has served on a Home Office Committee on the Lighting of Factories and on a Board of Trade Committee on Sight Tests. He is therefore eminently entitled to be heard on the subject now under discussion.

Sir Frederick Milner and Another. SIR FREDERICK MILNER, Seventh Baronet, is a member of the Privy Council. He has twice sat in Parliament, for York from 1883-85, and for the Bassetlaw Division of Notts from 1890-1906. He belongs to the type once described as having "Eton and Christ Church written all over him." He has taken a very prominent part in all movements for the after-care of the sick and wounded since the war began. Sir

Frederick Milner is no relation to Lord Milner, once known as Sir Alfred Milner. The last-named was at Oxford, where he was a first-class classic, but not at Eton. He was for some time the sub-editor of the *Pall Mall Gazette*, and then sprang into fame as the Governor of the Cape during the events which preceded the Boer War. He is the son of a medical man.

I CONTINUE to receive complaints on a subject which I have already mentioned—namely, the behaviour of medical examiners of recruits in the face of certificates brought by candidates from their own medical men. It is obviously unwise of examiners if they treat such certificates as necessarily useless. This seems certainly to have occurred in some instances, but I cannot believe that it is the usual practice. A great deal must depend upon how the certificate is worded. A document stating that in the opinion of the writer Mr. John Jones is unfit for military service must obviously be valueless to an examiner upon whom rests the responsibility of accepting or rejecting an applicant. But a certificate which gives cogent reasons for the opinion, and thus calls the examiner's attention to points in the case which might easily escape a hurried examination, ought certainly to be treated with respect, and if the signatory is a reputable medical man, I imagine it would be—but not always, I fear.

It has, of course, been suggested that doctors give certificates "out of kindness," and the *Daily Graphic* says that if the examiner finds that this is being done "he can report the matter to the British Medical Association." Of course he can. He can also report the matter to the Upper Tooting Bicycle Club. The one course would be as impressive and as efficacious as the other. If, however, it were reported to the General Medical Council, and that body were to regard such behaviour as "infamous in a professional sense," the consequences would be very serious. According to the *Daily Graphic* the present state of matters is as follows: "Unless a man is obviously unfit he is not rejected under the Derby scheme. He is put into his group. Then on the day he is called up he is given a warrant and sent to the depot, where he is examined by the Medical Board. The Medical Board may find him fit for foreign service, or for garrison duty at home, or for clerical or other sedentary work in the Army; or it may find him unfit for any military service. In the last case he will be discharged, but in any of the other cases he will be treated for service according to the finding of the Medical Board." I feel sure that a carefully worded medical certificate presented to such a board would receive every consideration. But it should be carefully worded.

A LETTER which recently appeared in the *Daily Express*, signed by Maurice Arnold, is not without interest in this connection. It is entitled "Dodging the Army Doctor." "As a contrast to the patriotic endeavour to

hide any little defect from the eagle eye of the examining medico is the great anxiety displayed by a certain class of young men (?) to inform the doctor of various past ailments, which in some cases are the deciding point which grants a certificate of unfitness. One youth recently was doubly successful in his desires—rejected by the Army doctor and passed as a first-class life by an insurance company's M.D." The astonishing thing to me is that anyone who wants to "slack or funk" should take the trouble to "dodge" the Army doctor. All such a person has to do is to raise his right hand to the heavens and, blubbering, affirm that he has a conscientious objection to being wounded or even vaccinated. He would then escape scot free. How a male Government in a time of crisis can have any truck with such pusillanimous tomfoolery passes comprehension. Even in the face of the enemy we continue to be governed by the precepts of old maids and the cowardly casuistry of the castrates.

DR. WILLIAMSON, the Medical Officer of Health, and Dr. Guy, the Tuberculosis Officer, of the city of Edinburgh, have recently been expressing some very decided and

rather iconoclastic opinions on the way in which money is spent in the campaign against tuberculosis. The views of these gentlemen demand very serious consideration, not only in Edinburgh, but all over the country. Dr. Williamson, at a recent health congress, said that sanatoria and dispensaries, while useful aids in carrying on a general crusade against consumption, "are not of themselves likely to be attended by markedly beneficial results in the absence of other definite preventive measures." These, he said, centre largely on the housing question. Dr. Guy, in his latest report to the Burgh Insurance Committee, said: "The housing question is one of the vital points in dealing with the problem of tuberculosis. Hitherto we have heard a great deal about sanatoria, etc., and too little about these houses. The disease should be attacked there; and my opinion inclines to the belief that if all the money which is at present being poured out on sanatoria had been spent on an improvement of housing conditions, the results would certainly not have been less satisfactory."

It is certain that every trained hygienist will agree with these opinions, and it would be a good thing if similar officers in other localities would continue the crusade on these lines. SINAPIS.

MR. CORNELIUS SURGEY, of Hounslow, bequeathed £5,000 each to the Metropolitan Convalescent Institution, 32 Sackville Street; the Home for the Dying, North Side, Clapham Common; St. Mary's Hospital, Paddington; the Freidenheim Hospital and Home of Peace for the Dying, Swiss Cottage; the Hospital for Sick Children, Great Ormond Street; and £1,000 each to the Trained Nurses Annuity Fund; the Cottage Hospital at Harlington; the Hospital at Hounslow.

THE X-ray equipment of the No. 1 Canadian Hospital at the front is now being utilised in experiments directed towards the cure of frozen feet, and surgeons believe the experiments will prove to be a success.

PERISTALTIC PERSUASION.

The paper read before the Balneological and Climatological Section of the Royal Society of Medicine by Dr. Campbell McClure, which appears in another column deals with matters which concern not only the hydrologist, but every thinking practitioner of our art. The work already done by Dr. Campbell McClure in conjunction with Drs. Mitchell and Wethered, showing that the stomach could be made to contract by gentle stimulation of the skin over the left costal margin, had broken fresh ground and prepared the way for further developments. These developments were hastened by Professor Keith's Cavendish Lecture, in which were described the various motors of the intestinal tract and the connection of these "nodal" areas with the probable causes of intestinal stasis. The next step was to ascertain if there were any areas in the abdominal integument by stimulating which an effect upon the intestinal nodal areas could be produced which was similar to the effect produced upon the stomach through the area about the left costal margin. The answer to this inquiry has been in the affirmative, and the road to further investigations is thus opened up in an atmosphere full of promise. Much still remains to be done, but with the principle firmly established, the details ought not to present any insuperable difficulties.

The treatment of intestinal stasis thus passes from the empirical to the scientific, from the exhibition of drugs to the education of reflexes. For there can be little doubt that in dealing with these nodal areas and their *modus operandi* we are in the presence of reflexes which, when seriously interfered with, lead to intestinal stasis. The interference may have been voluntary or involuntary; involuntary as the result of disordered function elsewhere; voluntary in the suppression of unseasonable and untimely defæcation which civilised conditions necessarily impose. In a paper written many years ago entitled "Was Luigi Cornaro Right?" the late Mr. Van Someren, of Venice, pointed out that we had lost or abolished a pharyngeal reflex which, when re-educated, prevented us from swallowing food until, by mastication and insalivation, it had been rendered fluid and tasteless. How we came to lose this reflex was not explained, but it is not difficult to imagine that the haste of competitive existence would not allow of the leisurely mastication upon which the integrity of the reflex depends. That particular reflex was inhibitory, the reflexes which Professor Keith described lower down in the tract are for the most part activating. It is probable that some of the constipation from which so many members of civilised communities suffer is caused by the over-education of the mechanism by which these reflexes are controlled. A proper control is essential in civilised life, and from the fact that it is so early acquired by human beings, we must suppose it to be easily acquired. Nor is it difficult to believe that necessity and force of habit may lead to the controlling action becoming so predominant as finally to suppress the action of the reflex itself. If

this be the explanation, then the problem which therapists have to solve is that of the best and simplest means of re-educating these smothered reflexes. That one way of doing this is to stimulate certain cutaneous areas by gentle rubbing with the finger, Dr. McClure has shown, but, as Dr. Campbell Thomson pointed out, there remain at least two problems which this suggestive paper leaves open to future determination. One of these is the best means of applying the stimulation; the other, the precise areas which must be stimulated in order with certainty to excite the various reflexes.

Apathy of the various abdominal organs; the dilated stomach, the sluggish liver, the visceroptosis, the V-shaped colon, the splanchnic venosity, have occupied a very large place in our clinical nomenclature, our pathological explanations and our surgical excursions, for many years past; and voluminous is the literature which deals with the avoidance and correction of these troubles. A very large proportion of the invalids who crowded to the Teutonic spas before the war were patients of this type—Carlsbad, Marienbad, Kissingen and Homburg drew their clients almost exclusively from the abdominally opulent—and if it can be shown that a little peristaltic persuasion practised at home will afford a more certain relief to such people than a severe course at one of these resorts, the enemy will have good cause to deplore the scientific activity in this country which has managed to pursue its path in spite of the prevailing frightfulness.

But peristaltic persuasion, fascinating as it is in theory and facile in practice, must not be allowed to blind us to the importance of the skeletal muscles of the abdominal wall in the causation and maintenance of intestinal stasis. Visceroptosis has a very real existence, and dislocation of the abdominal viscera is just as potent a disturber of function as dislocation elsewhere. No one who is in the habit of palpating the abdomen (since the advent of appendicitis what patient escapes it?) can fail to be struck with the flaccidity and atrophy of the muscles composing the anterior wall in the vast majority of cases. The re-education of these muscles is an essential feature in any scheme for a *restitutio ad integrum* of the dislocated and disordered, viscera. And it is more than likely that a well-developed anterior wall will prove a more efficient conductor of the persuasive stimulus than one which is flaccid and inert. The present-day practice of prescribing supporting belts is admissible only if the belt is regarded as a crutch to remedy and support the prolapsed organs while the muscles are being re-educated to do their work. As additional supports to the rehabilitated muscles in elderly men and in women stretched by repeated pregnancies, the belt may certainly be allowed an honourable place; but even so, the development of the muscles themselves should not be neglected. Peristaltic persuasion then, good as it now is, and much better as it promises to be as the result of Dr. Campbell McClure's paper, must not be regarded, even in its own field, as constituting all the law and the prophets.

CURRENT TOPICS.

Tuberculosis and Field or Sea Service.

DR. BANKS, tuberculosis officer of the city of Aberdeen, has submitted a report to the Sanatorium Benefit Committee of the Burgh Insurance Committee regarding insured tuberculous persons formerly in receipt of sanatorium benefit who have joined the military or naval forces. The total number of such persons on January 12th, 1916, was 64, of whom 57 were on military and seven on naval service (minesweeping). Of these 58 were suffering from the pulmonary type of the disease, of which 34 had received sanatorium or hospital treatment for various periods.

Of the 64 tuberculous persons who enlisted, 19 have recently been on active service—14 at the western front and five on minesweepers. Of the 14 four were cases of neck gland and 10 of pulmonary tuberculosis; of the latter of whom four were in the third stage and six in the second stage: three were known to have had tubercle bacilli in the sputum. At least two of the five on minesweepers had bacilli in the sputum. Among the six discharged from service there was one who enlisted no fewer than three times before being finally discharged. None of the six had seen active service. This group does not include three who, having been discharged from one branch of the service, enlisted in another. Having in view the fact that only one of 14 men accepted for foreign service has broken down in health, and that only temporarily, Dr. Banks says we may fairly conclude that the conditions of life in the field are not unfavourable to the maintenance of the general health of the tuberculous patient, if the disease is not already too far advanced and active. The common belief that a great risk to health inevitably follows a continued exposure to the rigours of winter is not corroborated by the experience of these tuberculous soldiers. Indeed, it suggests that any risk that may exist is more than counterbalanced by the general influence for good which attends a life constantly led in the open air.

Veterinary Science.

THE steady growth and development of veterinary medicine is to be welcomed, not only for itself as a matter of utility, or as an abstract science, but also for its possibilities with reference to disease in the human species. In this department, pathology is perhaps that branch which at the moment appears to open up the widest vista, the comparison of lesions found in the human type with those occurring in the lower animals being of the greatest interest and value. In matters bacteriological and veterinary, at present we stand but upon the threshold—but it is not unreasonable to conceive that the study of infection in man and in the animal, by proceeding side by side, might throw much light one upon another, and come to be a source of mutual strength and progress. Much, if not all, of human physiology has been based upon the accurate study of animal function; if the same laws apply in health, as found by experimental investigation, why not in

disease, if we but study the phenomena closely? And in the matter of therapeutics, much experimental work might be done upon animals with a justification which similar procedures in the case of man would lack. Veterinary medicine is replete with possibilities, and in addition at the moment the profession is not overcrowded, so far as we are aware.

The General Practitioner.

EARLY specialisation, in the main, is the desideratum of the medical graduate of ability; even prior to qualification, his intentions are frequently already settled, and upon graduating, he hastens to some centre where special study is made of that branch which he proposes to follow. Without denying the necessity of the exclusive worker, we think that of recent years there may have been a slight tendency to overdo specialisation, and that the slow elimination of the general practitioner is perhaps a questionable benefit. There is much to be said for the family doctor, whose interest in his clients commences with their birth, continues during their infancy and childhood, with the ailments peculiar thereto, to cease only perhaps in advanced adolescence. Moreover, all medical knowledge is largely interdependent, and there are few circumstances with which a doctor may be confronted wherein a broad knowledge of practice, apart from the immediate question in hand, may not be of benefit. The pathologist, for example, seated in his laboratory, forms an ampler judgment of morbid anatomy and its activities, if he understands the clinical conditions associated with each lesion. So far from believing that specialisation should ensue practically immediately upon taking a degree, we venture to think that a few years' general practice would form a firm basis upon which to build, and that experience of the three great subdivisions of medicine are no handicap, but an adjunct to successful work in a more limited field.

The New French Infantry Shield.

At a recent meeting of the Reunion Medico-Chirurgicale of the Eighth Army, Dr. Noel Fresinger showed one of the new infantry steel helmets in use in the French Army. It had been perforated by a fragment of shell, and the members present were able to note *de visu* that the fragment had deviated owing to the resistance of the metal. Only a slight skin wound of the temporal region had been produced in this case, whereas, but for the helmet, the wound would have been penetrating.

There is no doubt that these helmets render very practical service, and the question arises whether they ought not to be adopted in the British Army. Dr. Bonnette suggested that the heart ought also to be protected, and stated that a steel plate 5 millimetres thick was sufficient to stop a revolver bullet fired from a distance of 7 metres. From a practical point of view, a thickness of 4 millimetres would be sufficient to protect the heart from the majority of modern projectiles. A plate measuring 15 by 15 centimetres, weighing 200 grammes, and

slightly arched so as to fit closely on the chest, fixed between the cloth and lining of the tunic, would serve the purpose.

Professor Laurent, of Brussels, approved warmly the idea, for he said he had come across quite a number of cases in which soldiers had been preserved from death by some metallic object worn over the region of the heart.

The Destruction of Body Parasites.

A SIMPLE method for destroying body lice has been proposed by Dr. Molle, Captain in the French Medical Service. Lice are lodged in the clothing, and Dr. Molle advocates ironing the clothing and underlinen with a hot iron. The method has been used with great success. An ordinary flat iron is moderately heated, and all the clothing is carefully and thoroughly ironed. For the body linen, simply passing the iron over it is sufficient to destroy the parasites and nits. For the clothes, care must be taken to pass the iron several times over the seams and to use the iron rather hotter.

Improved Methods of Drainage in Surgery

DR. CHAPUT has now for some months past quite given up the use of ordinary tubular drains, and uses "filiform" drains. The latter, it seems, act much better than the tubes, recovery being more rapid and scars insignificant. He uses threads of varying thickness, according to the cavity to be drained. For chronic abscess, where as small a scar as possible is desired, he makes use of capillary drainage (horse-hair); in abscesses the size of the fist he uses "filiform" drainage (silk thread or rubber threads about 3 millimetres in diameter); for large cavities he uses cylindrical drainage (rubber cylinders from 6 to 7 millimetres in diameter). He presented several patients thus treated at the Society of Surgery, amongst others being cases of acute sub-maxillary abscess, chronic abscess of the buttock, empyema, frontal sinusitis, acute abscess of the neck.

Meningococcus Carriers.

MODERN doctrines of the epidemiology of cerebro-spinal meningitis leave the practical problem of dealing with infection in a very difficult position. If it be true, as is suggested, that during the period of an epidemic an indefinite number of the general population, up to ten per cent., according to some authorities, are infected by the presence of the meningococcus in the naso-pharynx, it is clear that no general scheme of isolation of such infected and infective persons is feasible. It is, moreover, peculiarly unfortunate that no ready means of distinguishing the meningococcus is as yet available. As a matter of fact, it is a matter of extreme difficulty to establish the identity of a suspicious organism found in the naso-pharynx, either positively as the meningococcus or negatively. Hardly one of the ordinary tests is constant, and, prior to their application, it is usually necessary to isolate the suspected organism, an undertaking which in itself may require considerable time. In

view of this difficulty of identifying the meningococcus, we may be sceptical in regard to the source of the more generous estimates of its frequency. There is, however, more attention and research being devoted to the subject at present than at any previous time, and we may hope shortly to possess a more adequate knowledge of this interesting disease and the methods by which infection is carried.

War Substitutes.

THE cutting off of our supplies of chemicals and surgical instruments ordinarily obtained from Germany has given a great opportunity to English manufacturers. In many cases the opportunity has been seized, and British houses are turning out articles which are entirely satisfactory, and should be able to hold their own in open competition when normal conditions return. On the other hand, certain dishonest people are attempting to seize the advantage of a temporary market by producing articles which can hardly be considered as other than forgeries of the well-known articles whose names they bear. They are in appearance deliberate imitations of valuable articles, and it is only by sad experience one learns the difference in quality. Hypodermic syringes, for example, made to look like certain old favourites of German origin, are found by the test of a boiling or two to have been made of glass which crumbles on heating. Again, drugs and medicinal preparations long used and valued, are suddenly found to be without virtue. The ingenious people who are playing these tricks are not merely robbing their customers—that will soon right itself—but they are giving British manufacturers such a bad name that they are severely handicapping those makers who are producing honest work.

PERSONAL.

DR. J. J. O'SULLIVAN has been elected Mayor of Waterford.

DR. W. H. THOMPSON has been re-elected King's Professor of the Institutes of Medicine in the School of Physic, Trinity College, Dublin.

DR. W. H. COUPLAND, Senior Assistant Medical Officer to the Royal Albert Institute for the Feeble-minded, Lancaster, has been elected Medical Superintendent of that Institution, *vice* Dr. Archibald Douglas, deceased.

DR. COWEN, the Poor-law Medical Officer for New Malden, has asked the Kingston-on-Thames Guardians to appoint his sister-in-law, Dr. Lucy Beatrice Harvey, as his deputy during his partner's absence in the R.A.M.C.

SIR GEORGE PILKINGTON, formerly M.P. for Southport, whose death is announced, was a medical man. After studying at Guy's Hospital, he qualified M.R.C.S. and L.S.A. in 1870, and for some years practised in Southport.

In his quarterly medical report to the Essex County Council, Dr. J. C. Thresh, County Medical Officer, writes:—"I regret to have to record the death of Dr. Argles, Medical Officer of Health for Wanstead. I had known him for about 25 years, and always found him a most conscientious worker and one of the most charming of men. By his death the public health medical service suffers a real loss."

ORIGINAL PAPERS.

THE HYDROLOGICAL TREATMENT OF GASTRO-INTESTINAL STASIS.*

By JAMES CAMPBELL McCLURE, M.D.

Physician to the French Hospital in London, and to the Hospital for Consumption, Margaret Street.

GENTLEMEN,—I feel that some apology is due to you for the fact that although this paper bears the title of "The Hydrological Treatment of Gastro-intestinal Stasis," I intend to dwell at some length on the causation of intestinal stasis, and to limit my remarks on hydrological treatment to a somewhat small compass—having regard, in this connection, to principles rather than to detail. I feel that it would be presumption on my part to do otherwise, as I am addressing an audience of men who for the most part have devoted many years to the practice and study of hydrology. At the same time, an onlooker like myself has certain advantages which distance lends in the estimation of perspective. I make no excuse for re-opening the subject of alimentary stasis, since the recent work of Keith and Alvarez has excited general interest in this much-argued question.

Before going further, I should like to state definitely what I mean by gastro-intestinal stasis. One naturally excludes cases in which delay in the passage of the gastro-intestinal contents is due to an actual obstruction in the stomach or bowel caused by a tumour or a cicatricial contraction. The type of stasis that we are considering is associated with an atonic condition of the alimentary tract, and delay in the passage of the contents occurs at certain points—namely, the stomach, the duodenum, the ileo-cæcal region, and the colon. I include the stomach because the consideration of stasis of a functional kind in this organ has been neglected, while too much stress has been laid on the intestinal condition. It is a well-known fact that ileal stasis may be either the cause or the effect of stasis higher up in the gastro-intestinal tract, and it is my experience that in a large number of cases of alimentary stasis a dilated and atonic stomach has to be dealt with before the intestinal condition can be ameliorated. It is well also to establish some sort of standard of alimentary stasis which is pathological, and I think it is right to consider that if one finds splashing on succussion, with some evidence of gastric enlargement, three and a half hours after food, there is definite evidence of gastric stasis. Similarly, if a bismuth meal be given, and has not left the stomach entirely at the end of four hours, gastric stasis is certainly present. It is my habit also to consider that if the ileum is not empty eight or nine hours after the ingestion of an opaque meal, or if most of the meal is not in the descending colon twenty-four hours after its ingestion, a state of true intestinal stasis exists.

The two most important theories regarding the causation of alimentary stasis which have been advanced are those of Arbuthnot Lane and Keith. One can, I think, without offence, describe Arbuthnot Lane's view as the extreme surgical view: he considers that stasis is produced by the dragging of an atonic bowel on firm peritoneal bands, with the subsequent formation of kinks, which cause obstruction to the passage of the gastro-intestinal contents.

The great objection to this theory is that neither on *post mortem* examination, nor on the operating table, nor on the X-ray plate, has ever been found an occlusion at the point of kinking, and no evidence has been produced of a dilatation or hypertrophy of the bowel behind the kink such as one would reasonably expect to find were the kinking sufficiently obstructive to cause serious delay in the passage of the intestinal contents for a long time.

Keith's theory is quite different. In the Cavendish lecture for 1915, and in a paper read before the X-ray Section of this Society on October 15th, 1915, he put forward the theory that alimentary stasis was due primarily to a defect of innervation, and said that he found that in the course of the gastro-intestinal tract there were definite aggregations of myenteric plexus situated at certain points in the stomach and intestine. The aggregations of myenteric plexus are found at the œsophageo-cardiac junction, at the pylorus, in the third part of the duodenum, at the jejuno-iliac junction, at the lower end of the ileum, and in the distal colon. These areas he called nodal areas, and he explained that their chief function was to regulate the rhythm of contractions in the segment of the gastro-intestinal tract immediately beyond them. He also drew attention to the fact that disturbance of the rhythm of contraction in one nodal zone affects the rhythm in other zones. For instance, if the rhythm were upset in the ileo-cæcal region, a corresponding upsetting of the rhythm was common in the duodenum. Keith made a very careful study of numerous specimens which he had obtained from operation and *post mortem*, and showed that in these nodal areas there were to be found gross pathological changes in the structures composing Auerbach's plexus. He considers that the structural changes found in the plexus are sufficient to derange the innervation of the intestine and cause stasis, and he also points out that stasis normally occurs in areas near the nodal zones. One cannot help feeling attracted by this theory of Keith's that alimentary stasis is caused by some disturbance of innervation in the gastro-intestinal tract, but I should like to venture further back in the history of this condition, and suggest that there is a disturbance of innervation before any gross structural change appears in Auerbach's plexus.

I believe that the firm peritoneal bands described by Lane, and the gross structural changes in Auerbach's plexus described by Keith, are both late events in the course of intestinal stasis, and are probably the result of a low inflammatory process produced by the action of toxins or bacteria which have passed through an atonic intestinal mucosa. It seems likely that intestinal stasis, apart from an infection of the gastro-intestinal tract, is a condition which may exist for a long time without giving rise to symptoms. We all know people who have lived long and comfortably, even though they have been the subjects of chronic constipation all their days. If, however, such a person were to acquire an infection of the gastro-intestinal tract, it is easy to see how the antecedent tendency to intestinal

*An address delivered on January 20th to the Section of Balneology and Climatology of the Royal Society of Medicine.

stasis would aggravate the effects of the infection. I do not think, however, that stasis always precedes infection. Infection may actually produce stasis in a susceptible person—that is to say, in a person whose nervous system renders him easily liable to disturbances of innervation in the gastro-intestinal region. The main point is that whether stasis precedes or succeeds an infection, there is in all probability an inherent tendency to disturbance of the gastro-intestinal innervation in all patients in whom alimentary stasis exists.

Following out Keith's theory that some disturbance of innervation is at the back of the condition of alimentary stasis, one may obtain a good deal of information by a study of what occurs in functional atony of the stomach, where a considerable degree of distension and dilatation of the organ may occur without there being any organic obstruction at the pylorus. In this condition one finds clinically an atony of the main body of the organ with a tendency to hypertonus or lack of proper relaxation of the sphincteric areas at the cardia and pylorus. To this state of sphincteric spasm Hertz has given the name of "achalasia," which is a convenient and descriptive term. It is interesting to remember, in this connection, that it is in these two sphincteric areas, at the cardia and the pylorus, that the two considerable aggregations of myenteric plexus exist in the stomach. Similarly, it is most probable that in the intestine there exist areas more or less coincident with the nodal areas described by Keith and Alvarez in which a sphincteric action may occur, although not so completely as in the cardiac and pyloric regions of the stomach. This is particularly noticeable at the lower end of the ileum, where the lumen of the gut is sometimes seen during an X-ray examination to be greatly narrowed, and the opaque contents are visible as a thread-like shadow.

It seems likely that in the stomach a condition of achalasia at the cardia and at the pylorus accompanied by an atony of the body of the organ is produced by some disturbance of the balance normally preserved between the action of the vagus and the splanchnics, and it has been pointed out by Percy Mitchell, Wethered and myself that this achalasia and atony may be corrected by stimulation of the skin over the left side of the abdomen in certain definite areas—namely, along the rib margins between the 7th and 10th costal cartilages, and over the lower borders of the ribs about the level of the normal upper border of the stomach. Similarly, it seems likely that a condition of achalasia of the sphincter areas in the intestine accompanied by atony of neighbouring internodal areas may be produced by just such a loss of balance between vagus and splanchnics. This condition would produce, as in the stomach, a stasis of the intestinal contents near these areas. Some little time ago I endeavoured to find out if there were other areas on the skin surface of the abdomen through which stimulation could be applied which would produce a more vigorous peristaltic action in the intestine, with increase of its tone. It occurred to me that the duodenum could be stimulated through a skin area a little above the point to which pain produced by the gall-bladder is referred, and also, recollecting how in tuberculous peritonitis pain is so often referred to the umbilicus, that one could possibly find skin areas in the umbilical region through which the small intestine could be stimulated. It is my belief that by stimulation of the skin just within the right costal margins above the point to which gall-bladder pain is referred it is possible so to stimulate the duodenum, and experiment suggests that a similar stimulation of the

lower part of the ileum and of the cæcum can be effected through an area of skin in the middle line just below the umbilicus.

Following up these observations, I endeavoured to find if similar areas existed through which various parts of the colon might be stimulated, and I conducted a series of experiments by which I tried to localise those points on the abdominal wall to which pain would be referred when violent overaction and cramp of the colon were provoked. I introduced a rubber bag into the rectum, inflated it very rapidly to over-distension, and I found that in the fifteen patients on whom I made the experiment the result was violent pain in the suprapubic region, deep-seated discomfort over the sacrum, and also discomfort of a much more superficial description in both iliac regions. I chose the two iliac regions as the probable stimulation areas, and I am becoming convinced that through these areas it is possible to induce increased peristalsis in the colon. Keith's observations on the aggregations of Auerbach's plexus seem to me to suggest an explanation of the occurrence of such skin areas, in so far as they hint at a possible spinal connection of a segmental nature with various parts of the intestine, and at the same time suggest strongly the direction of the paths by which pain may be referred from the intestine to various portions of the abdominal wall, and the paths by which an impulse from the skin may travel to produce a contraction of the stomach or intestine.

So far the hydrological element in this paper has been slight, but it seems to me that a study of those stimulation areas may be of great use to the hydrologist in the application of douches and in the explanation of the effects of baths of all kinds and of electrical treatment on gastro-intestinal stasis. One has to remember that in the gastro-intestinal stasis which produces symptoms, we are dealing with two conditions—an atonic condition of the stomach or intestine with delay in the passage of the gastro-intestinal contents, and also with a microbic invasion of the alimentary tract, which may either precede or follow the existence of such stasis. Lavage of the stomach is a useful and effective way of removing infection, and the drinking of large quantities of water, especially water highly charged with certain salts, may be very useful in washing out infection from the small intestine, or even from the large intestine, and the Plombières douche is certainly in many cases an extremely efficacious way of removing infective material from the colon. If, however, lavage of these various kinds is used alone, there remains, after the infection has been removed, an atonic condition of the gastro-intestinal tract which will encourage reinfection. It should be the object of the physician not only to remove infection, but to endeavour to prevent its recurrence, and it is here, I think, that the use of baths and douches of various kinds forms an important part of the treatment of alimentary stasis.

Baths and douches, however, must be employed in a careful and intelligent way, and I do not believe that it is sufficient to direct a powerful stream of water against the body to produce the maximum benefit. It is true that such a practice would undoubtedly increase the power of the skeletal muscles, which is an extremely important thing in intestinal stasis; but I believe that douches directed particularly to the stimulation of the skin in the areas which I have already described will produce a very much more powerful effect in restoring tone to the intestine than any more haphazard method.

One has to remember that in inducing contractions of the stomach and intestine by stimulating

various areas of skin, one probably acts by means of a true reflex. In the case of the stomach I have found that to excite this reflex repeatedly in a short time one has to employ stimulation of a very gentle kind, which must be intermittent. Ordinary massage of the abdomen is incapable of inducing the desired reflex action, and really heavy massage of the abdomen may, besides, be an extremely painful process. In a lesser degree the same remarks apply to the intestine; the stimulation must be delicate and intermittent. Personally, I use my fingers as the means of stimulating the reflex, and in the case of the stomach, at least at the beginning of treatment, this seems to be the best way, because one can observe by auscultation when a powerful contraction takes place, and cease stimulation for a time. It seems to me, however, that stimulation ought to be not only intermittent and delicate, but varied, even in the case of the stomach, so that after the patient has been treated for a time by digital stimulation, douches and baths might be employed with great advantage, not only to continue the stimulation, but to increase the power of the abdominal muscles. The douches and baths, however, ought to be of a somewhat different character from those at present in common use. I cannot imagine any sensation more horrible for a person with a neurotic temperament and hypersensitive body wall than to be suddenly smitten under the fifth rib by a stream of water violently projected by an unfeeling bath attendant. Such a process may result in one powerful contraction of the stomach, but carried on even for a few minutes might well induce cramp or sluggishness of the organ for some time afterwards. It is true that cutaneo-gastric reflexes can be produced by pain, but while other methods remain it is not wise to employ this as a therapeutic measure. I would suggest that in the treatment of gastric stasis sprays of varying degrees of hot and cold water, or that excellent institution, the under-water douche, in which the effects of bath and douche are combined, would be of service. Similarly, with regard to intestinal stasis, the mere haphazard douching of the patient's abdomen is not enough. Douching combined with ordinary massage may in a certain number of cases do good, but in many cases it does positive harm. The tender abdomen must be treated tenderly: it is not an unknown fact that rough handling of the right iliac region may induce serious discomfort in a person who has had appendicitis. I would suggest that in the treatment of intestinal stasis, the various skin stimulation areas, in the right hypochondrium, below the umbilicus, in the right iliac region and in the left iliac region, should be stimulated *seriatim* by douches of a suitable kind, and that such treatment might be followed up with advantage by the employment of various electrical currents. With regard to these technical details I speak with the deepest humility, and merely present to you the roughest possible sketch in the hope that someone may be able to fill in the details.

I should like to refer once more to the atonic and easily distensible stomach, which is so often found in conjunction with intestinal stasis. I have met many people to whom the drinking of vast quantities of saline water has brought severe discomfort, which has lasted long after the patient has left the spa at which he sought relief. I do not think that any patient should be subjected to treatment by the drinking of large quantities of water until an accurate estimate of the muscular power of the stomach has been made, and until the atonic stomach has been restored to something like normal action. The Plombières douche, too,

which is a very useful weapon in many cases, despite the humiliation which its employment brings to a proud man, is not always successful in patients of delicate stomach, not only on account of the mephitic vapours produced during its use, but also on account of the nausea which many patients feel during and after lavage of their rectum and colon. I have seen many patients who have been unable to tolerate the use of the Plombières douche, and in all of them I have found a tendency to atony and distension of the stomach. Such atony and distension may be a primary fault or may be the result of the colitis. One must remember the fact that disturbance of the normal rhythm of contraction in one gastro-intestinal segment may be reflected to another. I would suggest, therefore, that before the persistent use of the Plombières douche any condition of atony or stasis in the stomach should be corrected first of all.

I feel that I may have dwelt perhaps too long on the theories of the causation of gastro-intestinal stasis, but my excuse is that one cannot at the present day advocate any form of treatment without having the support of physiological and pathological observation.

DISCUSSION.

Dr. CAMPBELL THOMSON stated that he was much interested in Dr. McClure's paper, both from the neurological aspect and also in relation to the condition of acute paralytic dilatation of the stomach on which he (Dr. Campbell Thomson) had formerly made some observations. From Dr. McClure's investigations it appeared that in seeking to stimulate the walls of the alimentary canal two distinct points must be borne in mind—viz. (a) the particular areas over which stimulation, to be effective, must be made, and (b) the type of stimulation which it is necessary to use. The latter would seem to be the most important matter, and while agreeing with other observers that a strong and crude stimulus, such as arouses muscular contractions of defence, is not likely to be successful, he believed that further investigation is necessary in order to determine more exactly the nature and intensity of the particular stimulation that is likely to produce the maximum effect over a given area.

Dr. R. A. YOUNG congratulated Dr. Campbell McClure upon his paper as an example of the opportunities for research still afforded by careful clinical observation, and also as an illustration of the fact that it sometimes happens that the physician's researches might point the way to fruitful investigations on the part of the physiologist. He had long been convinced of the value of the method of cutaneous stimulation of the abdominal wall in gastric stasis, according to the method introduced by Dr. Percy Mitchell and further investigated by Dr. McClure and Dr. Wethered. He had seen very good results from its use in cases of atonic dilatation of the stomach, and concurred in the opinion expressed by Dr. Nevill Wood that it was possible for patients to employ the method themselves if it were explained to them and they were gifted with sufficient patience and persistence to employ it. The areas described by Dr. C. McClure as causing contraction in the duodenum and intestine were new to Dr. Young, and he suggested that it would be very interesting if Dr. McClure would, in his reply, give some further details as to the method of the stimulation he employed, and its direction. He quite agreed with the suggestions made for the utilisation of these areas by the hydrologist in his special forms of treatment. He would be glad to know from Dr. McClure if any observations by means of opaque

meals and the X-rays had yet been made confirming the effect of stimulation of these lower cutaneous areas in inducing contraction of the bowel. He also inquired whether any actual cases of stasis in the colon had been treated by this method. He was of opinion that the method was not as widely known as it deserved to be.

Dr. LEONARD WILLIAMS said: With much of Dr. Campbell McClure's paper I cordially agree; from some of it I most profoundly dissent. From the view expressed in his closing sentence I differ as profoundly as it is possible for me to differ from anyone about anything. As a clinician, I decline to be held in check by the mere laboratist; for there are more things in the heaven and earth of the human body than are dreamed of in test-tube philosophy. The physiologist will tell you that venesection is useless, and propounds inane paradoxes about bleeding a man into his own blood vessels. Experience tells me that venesection does good, and I shall continue to employ it whether the test-tubes ring in consonance or rattle in dissonance. The laboratist will tell you that the skin has no absorptive power. I know that it has, and I shall continue to cure syphilis by the inunction of mercury, in spite of the surly inability of the physiologist to explain the procedure.

In saying this, however, I must not be understood to belittle the work which the physiologist has so often done by pointing a better way to the clinician. Of this there could be no finer example than the masterly researches into the motors of the intestinal tract conducted by Professor Keith and unveiled by him in his Cavendish Lecture. These researches, as Dr. McClure has done well to insist, must necessarily colour our conception of the immediate causes of intestinal stasis and modify our hitherto accepted treatment. They point the way to the discovery and correction of the individual peccant motor. We shall no longer blaze into the brown as, with a Pil Carthartic Co., we are now clumsily in the habit of doing; we shall select our bird and admonish it either by tickling a cutaneous area or by some other stimulant which accurately fits the sloth.

In this very excellent and thoughtful paper, by his own researches into the skin areas to be stimulated in certain cases, Dr. McClure very appreciably advances us along this path, and his appeal to the practising hydrologist to cease blunderbussing the whole abdomen and to take to sniping at the indicated areas is both pertinent and timely. It is the logical hydrological outcome of the new gospel.

Of course we have had to suffer the microbe. In medical articles he takes the place of King Charles' head in Mr. Dick's memoirs. He cannot be kept out. But what, may I ask, is the microbe doing in this *galère*? What has he to do with the cause of intestinal stasis or its treatment either by hydrology or grabbling? That the microbe is a result of stasis is accepted as a matter of course. That does not surprise me any more than it shocks me to see a dandelion growing on a dung heap. What we want to know is why the dung heap is there; there, at the road-side, or there, in the intestines. The one is a matter for the police; the other for the pathologist. In neither case does it help us to fawn upon the flora. This bacteriological babble displays an extraordinary confusion of thought. You might as well ask me to believe that the dandelion produces the dung heap as to suggest that the *Bacillus coli communis* causes the stasis. Bacteriology has its place, and a very large one it is, in the causation of disease; but in the name of common sense let us keep it in its place, and let us avoid the present tendency to drag in a

coccus by the scruff of the neck not so much to explain a pathology as to decorate and embellish a clinical picture.

In our apotheosis of the microbe we seem to have forgotten the Parable of the Sower, which tells us that the success of the seed implies suitability of the soil; if the microbe multiplies it is the fault of the *milieu*; improve your *milieu* by irrigating it with sound sanguineous fluid, and the microbe dies. "Who hath ears to hear, let him hear." And the way to secure sound sanguineous fluid is to take care of the internal secretory glands, those elusive tributaries of the liquor sanguinis upon whose proper balance so much depends. In the case of the abdomen, the glands which are presumably of the greatest moment are the members of the chromaffin system, with the adrenals at their head. If we would study the intestinal motors and their petrol supply, we must not forget the association of these glands with the sympathetic system nor the power of their secretion over unstriped muscle. Nor is it ever wise in connection with the ductless glands to lose sight of their interdependence. A lazy chromaffin system yielding a meagre tribute to the blood stream and causing stasis may be lazy because it lacks the wonted stimulus from—the thyroid I must not say, but the pituitary, the ovary or the testicle. It may be necessary—it often is—to look far beyond the obvious offender to find the gland round which the disturbance of function is stealthily gyrating. To be able to locate the individual intestinal motors is good; to be able to tickle them into their duty is better; but until we learn to include in the indictment the ductless gland or glands which are failing to deliver the necessary petrol, we shall fail of our larger purpose, tickle we never so cunningly.

THE EFFECT OF THE WAR ON THE MEDICAL PROFESSION.*

By CHARLES M. BENSON, M.D., UNIV. DUBL.,
F.R.C.S.I.,

Surgeon to Sir Patrick Dun's Hospital, Dublin; President of the Dublin University Biological Association.

WAR has now been raging for fifteen months, and it is possible, in some degree at least, to judge of its effects, immediate and remote, on the medical profession. Statistics are generally considered dry, and I do not propose to inflict many upon you this evening; but it is necessary to mention some figures which are of immediate interest.

In the year 1903 there were 37,878 medical men registered in the United Kingdom, and at the end of the year 1913 the number had risen to 41,940, after deducting removals by death, resignation, etc.—an average increase of 400 per annum. This increase was maintained in 1914, and the total number of registered medical men on the Medical Register this year is 42,378, in spite of a very large number of removals from the Register under Section 14 of the Medical Act.

Prior to the year 1914, between 1,050 men and 1,150 new names were added annually to the Medical Register, and it is a significant point that in 1914 the new registrations totalled 1,433—an increase of 265 on the previous year.

You may remember that shortly after the outbreak of war supplemental examinations were held by nearly all the licensing bodies in order that students who were prepared to be candidates for the final examinations might present themselves at once. This undoubtedly had the effect of "speeding

* The Presidential Address inaugural to the Forty-first Session of the Dublin University Biological Association, delivered November 20th, 1915.

up" the senior students, who, on receiving their qualifications, were able to offer themselves for commissions in the Naval and Army Medical Services.

The figures for this year are not, of course, yet available, but from inquiries which I have made I understand that the number of new registrations is up to, or above, the average, in spite of the fact that a large number of comparatively senior medical students were given commissions in the combatant forces.

We may infer that the war has stimulated the senior students to become qualified on an average rather more quickly than they would have done in peace time. But what does it portend for the immediate future? Owing to the large number of students in their second, third, or fourth year who have received combatant commissions or have become surgeon probationers in the Naval Medical Service—many of whom have already fallen in the country's cause—the number of candidates who should be presenting themselves for the final medical examinations this year and next year is reduced to an alarming extent—namely, by a quarter of the average supply.

It is admitted that, even before the war started, the number of medical men was not considered sufficient, having regard to the increase in the population, the requirements of the State, the demands of the Colonies, and the passing of the Insurance Act.

Great demands on the medical profession have of necessity been made by the State for the service of the troops in the present crisis, and in spite of the good response of the members at home and abroad the services of thousands more are required, in order that the necessary reserves may be trained and ready for service.

Remembering that in time of peace the supply of doctors was barely sufficient, what has been the effect of the war?

In the first place it has shown that what was a bare sufficiency in ordinary times has been turned into a marked deficiency on the occurrence of a crisis. We have evidence of this since the State is calling for more, and yet more, medical men; in civil practice doctors are unable to obtain the services of an assistant; a *locum tenens* is almost unobtainable, and the work of thousands of doctors has of necessity been increased beyond the limit of safety as regards their own health.

More work is being done in the civil hospitals by a staff reduced in numbers, and the patients in Red Cross hospitals and convalescent homes are to a large extent being attended by civilian practitioners, making a further demand on their gratuitous services.

Secondly, it has enhanced the value of the doctor from the "commercial" point of view, as evidenced by the fact that the State offers the recently qualified man an income of £400 a year; doctors willing to go as "assistants" are in a position to bargain, and to give their services to the highest bidder, and practitioners requiring a holiday, who have been able hitherto to obtain the services of a *locum tenens* at three or four guineas a week, are now offering, often unsuccessfully, eight, ten, or twelve guineas a week.

Thirdly, the numbers removed from the Register by death will undoubtedly be increased as the direct or indirect result of the war.

And in the fourth place, the war has proved that the profession of medicine, not being overstocked, holds out attractions to parents with sons and daughters requiring a profession.

Turning to the Register of Medical Students we find that in the United Kingdom in each of the

years 1909 and 1910, roughly 1,500 students were registered. In the two following years the numbers fell to 1,232 and 1,397 respectively, and increased in 1913 to 1,480.

In 1914 there was a further increase of 120, the total number being 1,600. We have to go back to the year 1898 to get an "entry" of similar number, and to 1896 for a larger entry.

The figures this year are not available, I regret to say, but from inquiries I have made I am assured that the numbers will be increased as far as Ireland's share is concerned—a larger proportion than usual being women students.

In Scotland the entry is only a little below the average, the number of women students being unusually high.

In England, however, the falling off is most marked. At Cambridge, for instance, only 41 students have entered as compared with 116 in 1913. At St. Thomas's the entry is only 45 per cent of the average. At Guy's, King's College and St. Mary's the decline, as compared with the average for the three years prior to 1914, is about 15 per cent. At the London School of Medicine for Women, however, a record has been made, the number of entries being this year 110, as compared with 69 last year, and an average of 44 for the three years preceding the war.

The immediate effect of the war on the medical schools was that a large percentage of the second and third years' men who felt that they could not expect to be qualified before the war was over, volunteered and received, through the Officers' Training Corps, commissions as combatant officers.

A small percentage of the fourth years' men followed the same course, or became surgeon probationers in the Navy, but the majority were persuaded to continue their studies, to give their help urgently required at the civil and Red Cross hospitals, and to complete the training which would make them still more efficient to help the State. They now are reaping the just reward of their patience.

Doubtless, many of those who intended joining a medical school in October, 1914, found the call to arms a greater attraction, but to judge by the figures from the Students' Register, many perceived that the deficiency in the number of the profession would have to be made good in the near future, and that the sooner the long and arduous course of preparation was started, the sooner would they be in a position to offer their services to the State or the public.

From what I have said it is inevitable that the incomes of the medical schools will in the near future be diminished by the decline in the numbers of students. They will, of necessity, be further crippled as a result of the opinion recently expressed by Lord Derby against the recruitment of medical students. The entries for post-graduate courses have been reduced by over 60 per cent., and this will still further diminish the income of the schools.

The war has given women an opportunity of proving their mettle, and that they have taken it with earnest enthusiasm is common knowledge. The members of our profession at home and abroad have every reason to acknowledge and to be grateful for the invaluable work they have accomplished in Red Cross and other hospitals; not only in the nursing of their patients, but also for the continuous supply of medical requisites and comforts for the patients.

War has had the effect already of levelling many prejudices, and not the least among them is that

against the women members of our profession many of whom have been successful candidates for appointments hitherto not open to them.

We know that in many hospitals in France and Belgium a woman doctor may be found on the staff, but Dr. Louisa Garrett Anderson was the first to organise and work a Red Cross hospital, completely staffed by women doctors. Such was her success in Paris that she was requested to organise and take charge of a hospital with 550 beds in London.

To these examples and successes must be attributed the large increase in the number of women students on the *Register* this year.

The decision of the Earl of Derby that "it is the duty of medical students other than those in the fourth and fifth years of study to join His Majesty's forces" was made public early this month, and this decision was given after considering all the arguments to the contrary that were urged by a most influential deputation.

It is not for me to question that decision, but I may be permitted in this paper to enumerate some of the considerations that were, doubtless, urged by the deputation:—

1. That the medical student will be of more service to the nation if he continues his studies and qualifies in three, four or five years' time than if he joins the Army as a combatant at present.

2. That the country requires, and will require, more doctors, but is getting, and will get, fewer.

3. That the number of students at the ten leading English medical schools during the first year of the war was 1,891, as compared with a normal total of 2,562, and a great many of this diminished number have since joined the combatant forces.

4. That it is not for the ultimate good of the nation to paralyse for three years the supply of doctors which before the war was barely sufficient, and which as a result of the war will be, in any case, rendered insufficient to a marked degree.

5. That the medical schools have a claim for consideration. The cost of their upkeep does not, and cannot be made to, vary in proportion to the number of students attending. Their incomes, which are largely, and in some cases altogether, derived from the fees of the students, have been perilously reduced, and a further depletion of students will spell financial ruin, in that they will be unable to maintain what the state requires, and rightly requires—viz., a high state of efficiency.

6. That it is not to the interest of the country to induce students to begin medical studies at the early age of sixteen.

7. That if the supply of properly qualified men is cut off, the deficiency will lead to a deplorable lowering of the standard which we have for years past endeavoured to maintain in the interests of the country and of the profession.

Let us now consider how the question of supply and demand will stand when the war is over.

At first sight it would appear that the release of those holding temporary commissions in the services would cause, so to speak, "a glut in the market" of medical men for civilian practice.

I do not believe that this will be the case. The establishments of the Navy, and still more of the Army Medical Service, will have to be kept up for some years at a much greater numerical strength than heretofore, and the places of those who have fallen will have to be filled up, with the result that a very large percentage of the younger members holding temporary commissions will be offered and will accept permanent commissions. Then there must necessarily be a large number of

the senior members of the regular services who, being eligible for pensions, will seek retirement after the arduous work of the war. There must of necessity be others who will be forced to retire on account of disablement or ill-health. The more senior civilians who have received temporary commissions will, no doubt, come back to civilian practice; but they will not affect "the market," as they will but take up the work that was theirs in pre-war days.

The demand for candidates for junior medical posts will be out of all proportion to the supply available.

Referring to the subject of medical students and recruiting, Mr. Tennant stated in the House of Commons:—"I think that we must remember that we have first to win the war, and afterwards to encounter the problems arising out of it, *if they do arise.*"

I maintain that the problem of the deficiency of doctors for the community will have to be encountered, and the question is how?

The necessary numbers could be obtained:—(1) by lowering the standard of the examinations held by the licensing bodies; (2) by shortening the existing five years' curriculum; (3) by allowing posts hitherto held by properly qualified men to be filled by unqualified men!

The prospect is not a pleasing one in the light of the future interests of the community, or of our profession.

But of one thing there can be no manner of doubt—namely, that women doctors will play an increasingly important part in the near future in looking after the health of the nation, and that they are preparing to do so is evidenced by the figures in the *Students' Register*.

The Government will look to those responsible for medical education for a solution of the problem of deficiency, and unless some solution is forthcoming the State will allow posts hitherto held by medical men to be filled by those who are not licentiates of medicine, surgery, and midwifery.

Before the war, the State owed much to the medical profession, and since the war began who can calculate by how much that debt has been increased? Let us hope that the State will ever hold that debt in mind.

To meet the demand, the students must first be secured, and then trained.

I do not anticipate any difficulty, as soon as the war is over, in obtaining the requisite number of students.

The professional classes, from whom our recruits are almost exclusively drawn, are quite alive to the fact that there are many openings in our profession—at home and abroad—and, having themselves come into closer contact directly or indirectly with our actual work, they will be even more in sympathy with our profession, whose reputation, good before, has been enhanced by the war. That they will supply the students I am confident.

The essence of the difficulty as regards the training is the element of time.

How is this difficulty to be met?

The lowering of the standard of the licensing examinations would accelerate the passage of those who are at present, or will be in the near future, negotiating the stormy seas of study, but the very slight advantage to be gained in numbers would be many times outweighed by the obvious disadvantages attendant: such a solution is unthinkable.

If the five years' curriculum is to be considered a *sine quâ non*, I see no way of supplying the deficiency except by giving publicity to the fact of the deficiency and urging parents immediately

to put their boys or girls who are sixteen years of age to the study of medicine. The disadvantages of this course are many, from the point of view of the parents, the students, and their teachers.

But must the five years' curriculum, as at present interpreted, be considered a *sine qua non*?

If the answer is in the negative a very appreciable step can be taken towards the solution of the problem.

To put it briefly, an attempt must be made to modify the curriculum, which now takes five years to complete, so as to squeeze it into four years.

How this can best be accomplished must be decided by those responsible for medical education.

There would appear to be a possibility of curtailment—(a) the "systematic lectures" on subjects which are also taught practically; (b) where time is of such importance, the summer vacation. This would involve a strain on students and teachers alike, but it should be borne in mind that the strain of war will be felt by every branch of the community, including our profession, for a very long time after the day that peace is declared.

Let us now briefly turn to another matter.

The new problems of treatment which have arisen as a direct result of the war have given a further stimulus to research work.

I do not intend to dilate on this subject, partly because the result of the work hitherto accomplished is *sub judice*, and partly because it is difficult to estimate to what extent some of the methods, which have proved useful in war, will affect subsequent practice in normal times.

It is of interest to note that a great deal of the work which promises to have the most far-reaching effects is being done by graduates of this university.

The war has emphasised the benefits of organisation and the disasters attendant on the want of it. Will the lesson be learnt and acted on by the medical profession? Time alone will tell.

Action in that direction is at present impossible, but I trust that the day is not far distant when such organisation will be undertaken, and will result in benefits to certain branches of the profession, such as the poor-law service in Ireland, whose conditions of service should be improved.

The industrial districts of England will be able to offer financial attractions to doctors quite beyond those obtainable in very many of the dispensary districts in Ireland, and for that reason the dearth of doctors will probably be most keenly felt in Ireland.

Hospitals are inalienable adjuncts to the medical profession. In Great Britain and Ireland the hospitals have been very largely maintained by the voluntary subscriptions of the public. Financial stringency as a result of the war has not yet been felt as much by the public as it will be during the next few years. When it is at its height, while industries and trade are in the process of recovering, it is inevitable that the voluntary hospitals will suffer and suffer acutely, and unless State aid is forthcoming many a ward must be closed.

I cannot conclude without referring to the members of the profession who are with the Forces. Of them a lay pen has written: "In the Great War not only was the Army Medical Service found to be in a state of complete preparedness and efficiency to meet the maximum demand which, according to previous estimates, could be made upon it, but also when the reality was found to exceed that estimated maximum many times over there was enough patriotic energy to make the huge deficiency entirely good."

We who are members of the profession can best appreciate what those demands involve. We know that the difficulties were met and overcome only by most superhuman efforts of endurance at the call of duty.

The health of the troops and the testimony of the wounded bear witness to the way in which the work of the medical service is being carried out, and it seems that one unquestionable effect of the war on the medical profession will be to enhance its already honourable reputation.

PENETRATING WOUNDS OF THE CHEST IN WARFARE.

By H. PERREAU, M.D.,

Surgeon in the French Army Ambulance 12-22.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE question of penetrative wounds of the chest in warfare is one of sufficient importance to justify our returning to the subject now and again. On this occasion I propose to formulate the conclusions at which I have arrived with the experience gained during seven months at the front, of 117 chest wounds, of which number 67 penetrated the chest.

We are always taught to regard absolute immediate immobility as the first, and often the only, suitable treatment of penetrative wounds of the thorax. It is therefore important that we should make our diagnosis as promptly as possible after the arrival of the wounded, so that they have the benefit of immediate immobilisation which may be the means of saving life. So convinced am I of the importance of this immediate immobilisation that I set aside a ward for the reception of these cases adjacent to the reception room, so that they could be transported thither with a minimum of disturbance.

I have just pointed to the importance of making the diagnosis of penetrating wounds of the chest at the earliest possible moment after the arrival of the wounded at the ambulance, but, as a matter of fact, this diagnosis is by no means always an easy matter. It is easy to make the mistake of taking a non-penetrating for a penetrating wound, but this entails no disadvantage for the patient, for after all, the enforced immobilisation can do him no harm, may even expedite healing. On the other hand, in an ambulance with a limited number of beds, the mistake would tend to reduce the number of beds remaining at our disposal for operated patients, for the gravely wounded and for non-transportable cases.

The direction of the track of the projectile and the situation of the apertures of entrance and exit are apt to prove misleading, because projectiles often run round the chest wall without entering the cavity.

Pain and oppression are often absent in penetrating wounds and, on the other hand, are often well marked in non-penetrating wounds, especially when the superficial or seton wounds are multiple as in wounds inflicted by shell fragments or grenades, and also when ribs are fractured.

Blood-stained sputum and actual hæmoptysis are often met with in non-penetrating wounds and may not be present in penetrating wounds, whereas limited or general subcutaneous emphysema is one of the certain signs of wounds of the respiratory apparatus. As a rule stethoscopic signs are of no assistance when the wounded reach us, because at the onset neither auscultation nor percussion yields any useful information.

The diagnosis of penetrating wounds of the chest is therefore often a matter of difficulty and

radioscopic examination is of the greatest assistance in these cases; indeed, it has on various occasions enabled me to transfer without detriment subjects who, without it, would assuredly have been thought to have penetrating wounds of the thorax.

I have insisted on the necessity for *immediate* immobilisation in these cases, but it must also be sufficiently prolonged to obviate consecutive complications, which are pretty frequent, or to mitigate their mischief when they do occur. Among these complications may be mentioned:—

(1) *Embolism*, which may be caused by any sudden movement, even after a lapse of time, and may prove rapidly fatal. I can recall one instance in which fatal embolism occurred on the twelfth day consequent on the effort to sit up, although the patient was thought to be out of danger.

(2) *Pleural effusion*, which is very common, sero-sanguinolent and hæmorrhagic, soon becoming purulent. This exudation is accompanied by the usual signs of pleural effusion, but it has seemed to me that the effusion is, as a rule, not very abundant and that it is exceptional in left-sided effusions for the heart to be displaced or for there to be any diminution of resonance in Traube's triangle, at any rate, as long as patients are immobilised in the ambulance.

(3) Subcutaneous emphysema, either limited or more or less generalised.

(4) Broncho-pneumonia and hæmorrhage from the lung are rarely met with in ambulances because they are, as a rule, too rapidly fatal.

The frequent complications: the embolism that so rapidly proves fatal, and the effusion that so readily becomes purulent, necessitating free thoracotomy, which takes so long to heal, render the prognosis gloomy. All the more important is it, therefore, to institute a treatment which may help us to obviate or reduce the frequency and the gravity.

This treatment, as already stated, is *immediate, absolute, prolonged* immobilisation.

This is how we proceed: as soon as a chest case comes into the ambulance, the patient is gently transported into the ward reserved for such wounds. There he is undressed and put to bed with every precaution, the wounds are dressed as aseptically as possible in order to lessen the frequency of renewal (every four or five days) and a wide body bandage securely immobilises the thorax. When pain and oppression are pronounced morphia is given in order to secure the necessary repose.

During the first two days the patient is kept on water diet and fluids are administered with an invalid cup (with a spout). This initial diet is not without its importance and has yielded me excellent results. It enables the patient to remain perfectly still, he is spared the troublesome effort to raise the head and it obviates the risk of vomiting, the consequences of which might be very serious.

During at least the first two days the patient is strongly advised to abstain from the slightest movement or effort of any kind, not even talking. I dwell particularly on these details because when embolism has occurred it was always when the patient was trying to sit up. After the third or fourth day the diet is gradually enlarged, the patients being fed with the spoon so that there shall be no excuse for sitting up. The immobilisation of the body as a whole is imposed for ten or twelve days, and I never allowed such patients to be transferred elsewhere before the fourteenth or fifteenth day.

The supervention of pleural effusion does not necessitate any modification of the treatment; indeed, I believe that complete repose greatly assists absorption of the effusion. I do not think that it

is desirable to perform thoracentesis in cases of hæmorrhagic effusion, because it almost always reforms and may even become more abundant.

Throughout the duration of this immobilisation it is important to watch the respiratory rhythm and the temperature curve because, as has been mentioned, the pleural effusion is very apt to become purulent and this occurrence is shown by a rise of temperature with wide oscillations.

When suppuration sets in early and the effusion is copious, with disastrous effects on the general health, we must not hesitate to perform thoracotomy with a wide opening, resecting two or three ribs so as to allow the escape of the pus, whereupon the fever at once disappears.

When empyema only occurs later in the case, after ten or twelve days' immobility—that is to say, after the period when embolism is most to be apprehended, I see no objection to the transfer of the patient to more stable institutions where the necessary surgical interventions can be carried out in accordance with the notes on the hospital ticket.

In cases of penetrating projectiles that have remained within the chest, I do not think we are called upon to operate in the ambulances near the fighting line; indeed, for my own part, I have not witnessed any accidents from the presence of projectiles in the lung or even in the pericardium, as seen by radioscopia in two instances.

In the first case the bullet pierced the epigastric region and found its way into the pericardial cul-de-sac. The patient was transferred elsewhere on the 28th day in good health, with merely a slight effusion in the left pleura. In the second case the projectile entered in the subclavicular region and was localised by radioscopia in the anterior mediastinum to the right of the xyphoid appendix. A week later the patient presented signs of pericarditis, and puncture of the pericardium gave issue to two pints of fluid. Eight days after this puncture the patient was transferred in good health with only slight effusion in the pleura.

My conclusions are therefore that in penetrating wounds of the chest our duty in ambulances near the front is:—

- (1) To make an early diagnosis, whenever possible by the aid of radioscopia.
- (2) Immediate, absolute, prolonged immobilisation.
- (3) Keep the patients on water diet for the first two or three days, not allowing them to raise the head to drink.
- (4) Such patients not to be transferred until after a fortnight's immobility.
- (5) During the first four or five days a daily dose of 10 cc. of camphorated oil.
- (6) Except compelled, not to attempt the removal of the intra-thoracic projectile.
- (7) Prompt, wide opening to give issue to early copious purulent effusions.

THE WAR—IMPRESSIONS: NEURO- AND PSYCHOLOGICAL.

By T. DUNCAN GREENLEES, M.D. EDIN.,
F.R.S.E., MAJOR, R.A.M.C. (T.),
Weymouth.

To those of us working in military hospitals many opportunities are given of noting the awful carnage produced on the human frame by modern methods of warfare; and, with an experience behind me of sixteen months, I have been most impressed by those cases, coming under our care, suffering from nervous and mental injuries and conditions consequent upon active service in the firing line.

These cases have passed rapidly over the range

of my mental vision with a kaleidoscopic effect, leaving but an evanescent image; but there were several which impressed me so much that I felt justified in recording these brief experiences (a) jotted down in the very short intervals of a strenuous life.

While the high explosive shell may produce very serious wounds, the mere explosion, and consequent sudden alteration in the atmospheric pressure, produce grave effects on the nervous system of those in the immediate neighbourhood. It is a condition of shock, but the term "concussion" has been perhaps more aptly applied to it. "Concussion," then, may affect the mental faculties, giving rise to profound mental symptoms, and in cases leading to actual mental disorder; or it may affect the spinal cord, causing paralysis of a temporary nature; or, finally, it may attack an individual nerve, producing local paralysis. I had one case of this latter condition under my care, where the muscles supplied by the musculo-spiral nerve were paralysed, and yet there was no wound visible, and the man informed us the conditions occurred immediately after a big explosion in his vicinity in the trenches. Lieut.-Colonel Barker, F.R.C.S., whom I saw in consultation over this case, expressed the opinion that "concussion" could affect the molecules of the brain, spinal cord, or individual nerves, upsetting, as it were, their normal order for the time being, and that, in his experience, these cases got quite well ultimately.

With respect to the cerebral cases—or "neurasthenia," as they are sometimes called—the utmost quiet is required in their treatment. These cases have the most intense dread of any noise—they generally sleep with their heads under the blankets; photophobia is marked, and they have a haggard, frightened expression, a condition more noticeable in the men who returned invalided from the first Expeditionary Force than in the more recent returns from the front. They sleep badly, have vivid nightmare, living over and over again in their dreams the agonising experiences they went through in the trenches. While at times fairly cheerful, they are more frequently irritable in temper, and cerebration is markedly torpid. There is general hyperæsthesia; one officer whom I saw professionally went into general convulsions when I approached to take his pulse, and one man started taking numerous severe and exhausting epileptiform fits. The expression may be vacant, and sometimes there is a "far-away look" in the patient's eyes, as if his thoughts were still in the trenches, with all their ghastly sights.

When the "concussion" affects the local cerebral areas controlling one or other of the senses, then there is entire obliteration of the functions concerned. While the ear-drum may be ruptured from the force of the explosion, it is certain in some cases deafness is present without this injury. During one of the engagements "somewhere in France" early last year an explosion occurred, and a man belonging to the 3rd Wiltshire Regiment was buried in the soil. A large mass of earth struck him on the back of the head, and when he was dug out it was found he was blind, the blow having been so severe as to have apparently "concussed" the occipital centre for sight. I saw him some months afterwards, and, taking a personal interest in the case, had him sent to Mr. Pearson's Home for Blind Soldiers in London, where he remained for about two months, and then came back to us. Everything pointed to the fact that the injury was functional, and therefore possibly only temporary; but

on his return he was as blind as he had been when he left, and, indeed, he thought himself he was worse, for whereas formerly he could distinguish between night and day, latterly he could not see light at all. The short time he was in Mr. Pearson's home he was trained most efficiently to take care of himself, and one could hardly realise he was blind at all, the confident way in which he could walk about, steering aside from obstacles even before he came up to them, and he moved about the ward slowly without the aid of a stick. It is wonderful how the other senses develop when the eyesight is destroyed, and one fact I learned in studying this case I never knew before, and that is by the sense of feeling, perhaps aided by the sense of hearing, a blind man can learn the various colours. In testing him I tried in many ways to deceive him, but he laughingly said I was "fooling him," "for," he would say, pressing between finger and thumb a piece of coloured cord, "I can tell this is blue, for blue has always a rougher feel than red," and he would make me try the experiment by rubbing a blue and red piece of cord, and listen to the difference between the sound produced by a rough-grained article and a fine-grained one; but I confess my other senses were not acute enough to note any difference. Here he combined both the senses of feeling and hearing in deciding the colour, and as his work consisted in making coloured net-bags I never found him fail in complying with the orders he received as to the colours selected. Is it that the "graining" of an article is regulated by its colour, and in this way the blind can tell the difference? This was his own explanation, but I am unable to express an opinion in what I consider a most wonderful provision of Nature.

Another case, and he is still under observation, was that of a man belonging to the 3rd Dorset Regiment, who was exposed in close proximity to the bursting of a shell, and became suddenly both deaf and dumb. The deafness was profound—he could not hear a loud sound immediately behind—although the tympanum was intact. Both deafness and dumbness were, strange to say, intermittent. If he were upset by any trivial matter he could speak and hear quite well for a few hours, and then the infirmity returned. On one occasion he was much disturbed when he was informed he was to be removed to another hospital—he preferred to stay where he was—and on the day of his removal he came to me quite excitedly and reported he could both speak and hear perfectly well, and that he wanted to go back to his regiment at once as there was a draft about to proceed to the front, and he was anxious to join them. Unfortunately the "cure" only lasted a day or so, and he is again deaf and dumb. It is suggested that hypnotism would be best for such a case, as it is a purely functional condition.

The cases of spinal "concussion" from high explosive shells I have seen are few. The symptoms are paraplegia of more or less severity, and of variable duration. No trophic changes occur in simple "concussion" such as is found in actual cord injury. Indeed, in many cases of gunshot wounds I have seen few where the cord has been implicated; I would not like to say that this experience was general, however.

Gunshot wounds of the nervous system is a subject so extensive that it can only be referred to briefly here. Given a perfectly clean, naked body, the modern bullet could pierce a channel right through it, and, unless it came in the way of some vital organ, the wound would heal quite satisfactorily, often by first intention, if the opportunity is

given it. Unfortunately, it is often the case that these aseptic bullets carry along with them some septic clothing, and as a result the trouble begins. I have been much impressed by the satisfactory healing of most gunshot wounds, unless complicated as above, or by the damage caused to bone, nerve or vessel. The wounds heal up in a very short time, leaving little scar, and no ill effects. Within the first nine months of the war I have passed as "fit" men who have been invalided home from wounds three times.

I have seen few cases of cerebral injury the result of gunshot wounds—possibly most of these cases are immediately fatal—and in only one case was there a bullet embedded, according to the radiograph, in the parietal region of the brain, giving rise to no marked symptoms, however.

The treatment of injuries to nerves, either from bullets or shrapnel, depends on the condition of the nerve. The nerve may be divided, partially or entirely, or it may be embedded in cicatricial tissue so that its functions are destroyed. Wonderful results have followed the tying of severed nerves, and the dissection of those embedded has, in my experience, resulted in restoration of their function.

I saw a large number of cases of "frost-bite" last winter, and I include this condition among my cases of neurological diseases. The name is a misnomer; "frost-bite" often occurred when there was no frost, but always when it was wet, and when the men were standing in wet trenches for a long period of time. Rather than being caused by frost, it is due to constriction of the circulation in wet surroundings. Except in rare cases of true frost-bite, there is no actual destruction of tissue; the feet are swollen, livid, cold, and perspire freely. The same condition was found in the hands. I believe "trench frost-bite" to be a condition of peripheral neuritis in which the thermal functions of the nerves implicated are at fault.

Again, "trench rheumatism" presents few of the symptoms of rheumatism, and must, in my opinion, be placed in the same category as frost-bite. There is less, if any, affection of the muscles than there is of the nerves, and the disease is undoubtedly more a "neuritis" than it is a "rheumatism." It does not respond to the usual remedies of rheumatism, baths of various kinds fail to relieve it, and the only cure is some form of dry heat. I thought it a great pity the scores of poor fellows suffering from "rheumatism" I saw last winter were not sent direct to Egypt rather than to this damp country. Everything was done for them here, but what was the use of medicines, with the glass low and raining nearly every day?

In concluding these somewhat rambling notes of some of my impressions, I would like to refer to the two departments of the British Army least open to criticism, and these are the A.S.C. and the R.A.M.C. The manner in which millions of men in the fighting line—all over the world—are being fed, clothed, and supplied with munitions of war in a continuous and ever-increasing stream, and the speedy and systematic manner in which the wounded are being tended in the trenches while still under fire, removed to the clearing stations, classified there, sent to the base hospitals, and finally, in many cases within forty-eight hours from the time of injury, removed to some comfortable English hospital, are marvels, and will redound to the credit of these two departments when the history of this war is written.

And a meed of praise for our brave boys at the front who are carrying this world burden on their shoulders for King and country. Never in the his-

tory of Great Britain, perhaps never in the history of the world, has there been such a war waged, and our soldiers have borne themselves like heroes and descendants of heroes. In South Africa, and again in this country, I have learned to know the professional soldier and to love him for what he is; he is not a haloed saint, nor is he the sinner he is sometimes depicted in peace times. He is loyal to his King and country, obedient to his officers, a true comrade to his chums, and never wanting in chivalry to a woman. He is proving himself every inch a gentleman and a man, and this cannot be said of our enemies, who are beasts, and—there is no German word for "gentleman"!

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

ABOUT EPIDEMIC NEPHRITIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am afraid I am not prepared to accept unproved hypotheses, even when they emanate from Vienna. But Klein and Pulay's view differs in some important particulars from Lieutenant McWalter (whose letter on the subject appeared in your last issue). They thought that protective inoculation for various intestinal diseases, of which enteric was one, might have produced pyelitis. They did not, as Lieut. McWalter does, assume that because they found *B. coli* in the urine, that the disease was therefore one due to another microbe—the *B. typhosus*. Thirteen speakers took part in the discussion which followed, and all with one exception disagreed with Klein and Pulay's view. It was pointed out that the curve of incidence of the intestinal diseases differed entirely from the curve of incidence of the nephritis, and that in many cases the disease was independent of *B. coli*. The readers of the paper laid stress on the abundance of leucocytes in the urine, as pointing to the condition being a pyelitis, but Dr. Mackenzie Wallis's recent work shows that there is a similar abundance of leucocytes in scarlatinal nephritis. In the American Civil War there were more than 14,000 cases of nephritis, although the number of troops in the Northern Armies never exceeded 700,000. Yet anti-typhoid inoculation was then unknown. Inoculation was largely practised in the South African War, and although typhoid was rife, nephritis was extraordinarily rare. Are we to conclude that whereas inoculation did not then modify typhoid fever in this way, it has now altered it beyond recognition? And if it did so in Flanders, why did it not do so in the Dardanelles?

I am, Sir, yours truly,

W. LANGDON BROWN.

60 Welbeck Street, London, W.

January 29th, 1916.

MEDICAL MEN OF LETTERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with great interest the instructive contribution to the history of medical culture which has just been presented in the columns of the MEDICAL PRESS AND CIRCULAR from the pen of Mr. Maidlow. The perusal recalled the fact that no department of human knowledge is too remotely placed to shed some illustrative light on the theory

and practice the healing art—the one profession which was practised and blessed by the Divine Saviour of Humanity during His earthly pilgrimage; for these take, or should take, thought for all the constituent parts and aspects of *homo sapiens*, both individually and collectively. Also, the fact that the medical armamentarium with which we are at present provided is really the resultant product of a thoroughly irregular and large incompatible mass of opinions and statements, much oftener forced upon public attention and recognition by faked report and furious advertising than by conscientious clinical record of obvious facts; or by scientific acumen, or logical criticism. Thus has gradually evolved the present *status quo*, in which the great majority of current remedies are employed and applied *because* they had been used in *presumably* similar cases by a popular clinical teacher of the past days of the curriculum; or stand recommended in the pages of the "Dictionary of Treatment," which is always conveniently placed within elbow range for ready reference by the prescriber. And so it comes to pass that the only safe practitioner—in the mind's eye of the really discriminating—is the member of the minority who has carefully and conscientiously assimilated a competent knowledge of the *history* of drugs and of symptoms, and who accordingly knows the origin of the stamp which has given each its present accepted face value.

This broad wave of whirling thought was brought to my mind on seeing the name of Oliver Goldsmith among those whose memory has been distinguished by the attention of Mr. Maidlow. I feel no fear of successful contradiction when I refer to the same as that, of all those known to the annals of medicine, which has secured the firmest hold on immortality. In confirmation of the view thus expressed, I will here mention no other corroborative testimony than the fact that statistics of quotation published about a year ago, by one of the greatest living authorities, show that "*The Traveller*" is the *most frequently quoted of all existing poems*.

But the above-mentioned are not the special considerations that have urged me to present myself in print on the present occasion. The stimulus was provided by the fact that Mr. Maidlow repeats the well-worn mis-statement of the regulation biographers of "poor Goldie": that he "was born at Pallas." The village of Pallas in the county Longford was the residence of the Goldsmith family at that auspicious date—hence the very natural mistake. A good many years have now elapsed since I recorded the well-established local tradition—far more reliable than the "copy" of the biographers—that Mrs. Goldsmith, in accordance with the universal practice of that part of the country (even down to the days of my own boyhood), in order to place herself under the most affectionate and most trustworthy supervision at the time of her approaching trial, had set out for her mother's residence near Kilmore, in the co. Roscommon. But the premonitory symptoms developed before the destined goal was reached; the patient was helped down from her pillow, and the future author of "*The Vicar of Wakefield*" first saw the light in the country homestead of a relative near the town of Elphin. My accomplished friend, the Right Hon. Michael F. Cox, M.D., subsequently investigated the question with the discriminating thoroughness which characterises his contributions to science and literature, and published his results in an exhaustive thesis.

It is interesting to note that the brilliant ornament of our profession whose name I have just

quoted is himself a native of Roscommon—quite near to the actual birthplace of Oliver Goldsmith. So, too, was the late Surgeon-Major T. H. Parke, the Medical Officer of the ill-starred Emin Pasha Relief Expedition. Then but a few miles off will be found the birthplace of one of the most gifted and accomplished of living Irishmen, Dr. Douglas Hyde. As I was myself destined by fate to emerge on this terrestrial stage within the superficial limits of the quadrangle thus mapped out, I hope to be pardoned for taking the opportunity of seeking a little momentary illumination by reflected light. Anyway, it must, I think, be admitted, even on the above evidence, that Roscommon has not failed to furnish its quota of the names which have secured permanent places in the niches of the Temple of Fame. This fact I wish to emphasise—all the more gladly, too, inasmuch as there has been no part of Ireland—and, indeed, few of the world—subjected to more deliberately grinding oppression and injustice. It was one of the special foci of the radiant activity of another Oliver, whose name and fame will always furnish a gruesome contrast to those of our beloved Goldsmith. When Cromwell passed his heavy and long-toothed harrow over the fields of verdant Roscommon, he appointed, from the ranks of his "Ironsides," two permanent official hangmen; for the maintenance of "law and order," and the administration of "justice." He endowed each with extensive abbey lands: one with those of Cloonshanville (near Frenchpark), where the recipient (Davis) utilised for the necessities of his office the horizontal branch of a roadside oak, not too far from his mansion—which, where deeply notched by the friction of the rope in its long years of service, gave way and was blown down one stormy day (within living memory) and fractured the skull of a passing peasant; the other (Ormsby), who was much more sympathetically active in the discharge of his duty, erected a gallows on his lawn at Tubberavaddy, where he enjoyed the extra delight of exhibiting his skill and patriotic energy to his family and household; and where "his first act of grace" was "to attack and surround the Abbey of Fuerty in this neighbourhood, put the inmates to death, and possess themselves of all that was portable in and about the sacred edifice." But the bright side of that gloomy picture now stands revealed in the fact that few parts of the British Empire have shed more of their best and bravest blood in the great common cause during the present destructive war. This fact should surely give special and very solid grounds for anticipation of a brighter and better future for Ireland, and a higher and a holier hope for the progress of the future generations of the human race.

I am, Sir, yours truly,

JOHN KNOTT.

Dublin,

January 20th, 1916.

[It is hardly necessary to mention among recent celebrities that Lord French, though born in England, is by descent a Roscommon man; moreover, he takes the name of "Highlake" in his title from that county.—Ed. M.P. and C.]

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am so pleased my paper has been noticed by Dr. McMillan, and I thank him for mentioning Dr. Carlyle. He deserves a place in my Valhalla! Of course, there are several men I should like to have included in my list, but I feared to become boring. In the periods I selected, there are, in case anyone should feel interested, Aiken, Arni-

strong, Sir Wm. Browne, Cowley, Grainger, Mason Good, Hamry, Harrington, Jurin, Jebb, Leyden, Sir Wm. Petty, Caleb Parry, Pettigrew, John Phillips, Sir Hans Sloane, and Philip Smiles—in alphabetical order. I wish someone would write a paper on them to supplement mine. A good many men have left their names in medicals annals for their medical literary work, but they can hardly be called "men of letters." The present Lamente must have justice done him in both capacities by some future scribe. As a matter of fact, most of us live in hopes of a good obituary notice!

I am, Sir, yours truly,
W. H. MAIDLOW, M.D., F.R.C.S.

Ilminster,
January 28th, 1916.

DIET AND THE CARE OF CHILDREN'S TEETH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—On the subject of dental caries more nonsense has been written than on any other within the range of human pathology. Up to about forty years ago most of this rubbish was imported from the United States. American dentists before that time were very imperfectly educated, generally and scientifically. This did not prevent great numbers of them from becoming consummate masters of their handicraft with enough knowledge to enable them to make the simple diagnoses called for in treatment of the teeth. Those who wrote about dental diseases addressed an audience less well informed than themselves, and no authoritative criticism was in action. I took the trouble to go laboriously through the mass of literature which emanated from the most prominent of these writers, and I had no difficulty in showing by copious citations that this was often worthless or incomprehensible owing to neglect of the common rules of grammar and the introduction of pseudo-scientific jargon with an invented corresponding terminology. I imagined that the manufacture of this kind of stuff either abroad or at home had been put an end to; but it seems that there are still to be found asserting themselves writers who put forth speculations entirely incompatible with demonstrated and easily demonstrable physiological facts. The nature of caries was made clear more than fifty years ago by Sir John Tomes. He was the first investigator armed with adequate knowledge to go exhaustively into the subject. He began by making clear the histological qualities of enamel and dentine. He showed that these tissues contained no physiological elements capable of carrying on vital or morbid processes; that they could be influenced only by agents acting upon them from without, and "therefore dental caries could not in the proper sense of the word have any pathology." Tomes's views were confirmed by all later investigators having any valid claim to authority. Among these Wedl, formerly Professor of Pathology at Vienna, was the most distinguished. He followed Tomes over the whole ground and fully confirmed his opinions. But in truth, any intelligent third year's student can demonstrate the histology of the dental tissues for himself. By slowly dissolving enamel he can see that it is merely a calcareous mass devoid of organic elements; and he can satisfy himself of the absence of any similar elements in dentine, with the exception of the minute fibrils which occupy the tubules. The predisposing causes of caries are inherent structural defects in enamel; irregularities and crowding of the teeth, which give rise to lodgment

of particles of food, and vitiation of the secretions in ill-health, which favour decomposition of such particles. Any attempt to improve the quality of the tissues after the crowns of the teeth are formed must be futile, and any such attempt after the teeth are erupted can only be characterised as absurd. Whatever helps to give a child "a good constitution" should give him good teeth, and a mother free from hereditary disease, healthy, strong, and well nourished is likely to produce offspring of the right quality. No special food or drugs can do anything for the developing teeth after their crowns are calcified. The early dates by which this is effected are stated in the text-books. A diet which calls for the exercise of mastication must tend to produce well-formed jaws; but when the teeth are crowded owing to ill-development of the maxillæ the only effective treatment is the extraction of a sufficient number of teeth to allow of the spreading apart of the rest of the set. The rules which should guide this operation are set down in the text-books. In these works will also be found an account of dental hygiene—the methods by which perfect cleanliness of the teeth may be insured.

I am, Sir, yours truly,
H. S.

January 27th, 1916.

FUNCTIONAL NERVOUS AFFECTIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—There seems to be a prevalent belief amongst the medical profession that Christian Science practice is a form of suggestion, according to the statements made by Dr. T. A. Williams in his lecture reported in your issue of January 19th. This is not the case, however. Suggestion is a system based wholly on the exercise of the human mind, and as this human or carnal mind contains within itself all evil, it has not the capability of producing anything really good or Godlike. Good can only proceed from God, the infinite Cause of all that is good, and not from that which St. Paul terms "enmity against God."

To understand Christian Science healing, one must discern the line of distinction it draws between the absolute and the relative. When Jesus declared, "Ye shall know the truth, and the truth shall make you free," He, of course, referred to the absolute Truth, that which is the same yesterday, to-day and for ever. The study of Christian Science enables one to understand this truth, which is the sole cause of Christian Science healing. It was always something that Jesus knew, never anything He blindly believed, that enabled Him to heal the sick and sinning and to raise the dead. He did not heal through suggestion, but, as He Himself declared, by the finger or Spirit of God. That He expected His followers to heal by His method is evidenced by His declaration, "He that believeth on me, the works that I do shall he do also."

I am, Sir, yours truly,
CHARLES W. J. TENNANT.

Talbot House, W.C.

[As our correspondence columns are always open to anyone who wishes to make a suggestion, to correct a misrepresentation, to comment upon a proposition, or to preach a gospel, we gladly publish the above. We will not insult the intelligence of our readers by pointing out the confusion of thought displayed in the above.—ED. M.P. and C.]

MR. LEOPOLD F. DAVIES, of HERRINGSWELL, Suffolk, bequeathed £3,000 to the National Hospital for Diseases of the Heart and Paralysis, Soho Square.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, DECEMBER 10TH, 1915.

SIR J. W. MOORE in the Chair.

TWO CASES OF WELL MARKED MYELOGENOUS LEUKÆMIA.

DR. PARSONS showed two cases of the above, both men of about thirty-five years of age. One had received prolonged treatment with benzol, having consumed about $1\frac{1}{2}$ quarts of the drug in the previous $1\frac{1}{2}$ years. The result in this case was most disappointing, in that no result was apparent except a gradual progress of the disease, the white cells having considerably increased in number and the spleen become much larger. Dr. Parsons said that this was in accordance with his experience of previous cases, in which he had seen merely a temporary improvement. He regarded benzol as useless in the treatment of this disease, and the case was now having a course of X-rays. He noted that both these cases were passing a normal amount of uric acid. Previous cases had given a similar estimation, and he questioned the accuracy of the statement that the uric acid output is increased in myelogenous leukæmia.

ABDOMINAL ANEURYSM.

Mr. W. I. DE C. WHEELER exhibited a case of a man on whom he had operated five years ago. The case was shown at that time in conjunction with Dr. Lumsden. Operation consisted in wiring by Colt's method. The man had worked hard since, and was free from symptoms. A pulsating mass could still be felt, but pulsation was not expansile and the bruit had disappeared. He considered the case cured.

Dr. WALTER SMITH congratulated Mr. Wheeler on the successful result, and confessed that when he saw the case five years ago he did not anticipate it.

Dr. KIRKPATRICK asked if any expansile pulsation was visible on screen examination.

Dr. HAYES, who had X-rayed the case on several occasions, said that he was under the impression that expansile pulsation had entirely disappeared, and that the shadow had become much denser, indicating consolidation of the clot.

RODENT ULCER ON THE RIGHT ALA NASI.

Dr. O'BRIEN showed (1) a man sixty-eight years of age, who had suffered from the above for sixteen years. He was treated with radium bromide—twenty-nine exposures, extending over three and a half months, varying from fifteen minutes to three hours—causing complete healing of the ulcer, with a sound, pliable cicatrix. (2) A woman of thirty-five years of age, with a similar condition of three years' standing. This case was also cured by radium bromide after fourteen exposures.

Dr. KIRKPATRICK asked whether histological examination of the ulcers had been made.

Dr. DRUMMOND asked for an expression of opinion as to the relative merits of radium and X-rays in these superficial cases.

Dr. O'BRIEN, in reply, said that histological examination had been made in the first case and pronounced positive. He had not done so in the other case in order to avoid deformity as far as possible. He admitted that considerable difference of opinion existed as to the relative merits of X-rays and radium in these cases, but he con-

sidered radium preferable for the deeper lesions or in positions like the canthus of the eye or where gland involvement had occurred.

PSORIASIS.

Dr. O'BRIEN showed a case of above in a child two and a half years of age, whose mother and grandmother had suffered from the same disease. He emphasised the rarity of psoriasis before the age of five years, and also the distinct heredity. The eruption, which was dry, scaly and papular, involved the knees, elbows, arms, legs and backs of hands. The chest and scalp were quite free.

Dr. WALTER SMITH thought that a number of these cases were really seborrhœic eczema, and the appearance of some of the spots in this case inclined to that diagnosis.

Dr. O'BRIEN said that he had borne this possibility in mind, but had come to the conclusion that the eruption was psoriasis.

TWO SUCCESSFUL CASES OF OPERATION FOR MALIGNANT DISEASE OF THE STOMACH.

Dr. PARSONS, in conjunction with Mr. G. JAMESON JOHNSTON, read a paper on the above subject. (1) J. K. was admitted to Baggot Street Hospital nine and a half years ago with signs of pronounced anæmia. On examination a distinct tumour was felt in the epigastrium. Stomach contents contained some blood and no free hydrochloric acid. A diagnosis of malignant disease was made. Mr. Johnston operated and removed the pyloric growth, which was examined by Dr. Wigham and pronounced to be carcinoma. The man has since remained in good health, and wrote recently to say he had just been married. (2) T. W., age 63 years, was admitted two and a half years ago, with gastric symptoms, which had developed some little time previously. An epigastric tumour was felt, with an absence of HCl in stomach contents. Pylorotomy and gastro-entrostomy were performed, and the growth found to be malignant. He kept well till quite recently, when he was admitted to hospital with "cramps in the stomach" and obstinate constipation. Masses could be felt scattered through the abdomen, and a diagnosis of secondary malignant deposits was made. *Post mortem*: No trace of malignant disease was found, but a condition of chronic peritonitis, the cause of which was quite obscure.

Dr. KIRKPATRICK commented on the unusual success of these cases where a palpable tumour existed. He had previously considered it necessary to get the case before any tumour could be made out. He asked whether any cause could be suggested for the peritonitis in the second case.

Mr. WHEELER said that although the operative mortality in gastric cancer was low, 80 per cent. of the cases in this country recurred, mainly because they were not seen early enough. He considered loss of weight and appetite, with gastric stasis, in a patient of the cancer age to be strongly suspicious signs. Removal of the growth should be attempted even in advanced cases, when a year or so of comparatively comfortable life could be anticipated.

Dr. MATSON enquired whether any signs of arterio-sclerosis were present in the second case, as this might account for the peritonitis. With regard to gastric stasis he had recently seen a case of gastric cancer in which this sign was absent.

Dr. PARSONS said the diagnosis in these cases was easy on account of the palpable tumour. The glands removed from the lesser curvature were free from secondary deposits. He quoted Mayo's figures that a 90 per cent. chance of recovery from the operation existed in gastric cancer, a 35 per

cent. chance of life for three years, and a 25 per cent. chance of life for five years. The second case presented no symptoms or signs of arterio-sclerosis, but he was quite unable to assign a cause for the peritonitis, and hoped to exhibit the specimen later at another section. The absence of free HCl was a very valuable sign, and though it might be absent in many other types of disease, he had found it present in only one genuine case of gastric cancer.

THE ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FRIDAY, JANUARY 28TH, 1916.

The President, DR. ROBERT HUTCHINSON, in the Chair.

DR. J. D. ROLLESTON (for Mr. Sidney Stephenson) showed a case of dyspituitarism in a girl, *æt.* 15. She was brought to the ophthalmic department with the complaint that the sight had been failing for three or four months, and that for one week she had suffered from headaches. Right vision, 5/5 J.1.; left vision, 5/36 J.1.; weak atropine drops (1 gr.) were prescribed, to be used to each eye three times a day, and when the girl was examined the following week she was found to have in the right eye + 0.5D. cyl., axis 180°, and in the left eye + 0.5D. sph. A note was made to the effect that the media were clear. On August 27th, 1914, the sight of the right eye had become reduced from normal to "shadows," while that of the left eye remained as it was on admission some seven weeks before—namely, 5/36. The sight of the right eye was stated to have failed suddenly two weeks ago. The pupil of that eye had lost its direct response to light. The media were clear. Both optic discs were pale, but the retinal vessels were of normal dimensions. The girl's personal appearance was somewhat peculiar, since she was inclined to stoutness and her eyes seemed rather prominent. For closer observation the patient was admitted to the hospital on August 27th, 1914, and remained until the following October 24th. She was found to be a bright, intelligent, and good-natured girl, whose every movement appeared to be normal. There was no tremor or alteration in sensation. The facial movements were normal, and there was no nystagmus. The functions of all the cranial nerves, with the exception of the second, were normal. During her stay in hospital there were occasional headaches, but no vomiting or vertigo. An examination of the blood, conducted a few days after admission, gave the following results:—Red blood corpuscles, 3,770,000; white blood corpuscles, 6,400; hæmoglobin, 65 per cent.; index, 0.86. The differential count was: Neutrophiles, 55; basophiles, 1; eosinophiles, 2; large lymphocytes, 9; small lymphocytes, 29; hyaline, 4; total, 100. The knee-jerks were brisk; there was slight ankle-clonus. Flexor-plantar response. The abdominal reflexes were present; the reflexes of the upper arm were easily elicited. No jaw-jerk. No facial irritability. The Wassermann reaction negative as regards both the blood serum and the cerebro-spinal fluid.

The girl was next seen on May 13th, 1915, that is to say, after an interval of almost nine months, when sight remained much as it had been on the date of the last note. The optic discs were pale, with no evidences of antecedent neuritis. The retinal vessels were of good size. The field of vision of the right eye could not be taken, but that

of the left eye, estimated for a small white object, was restricted in the temporal region, although tolerably full elsewhere. On June 17th, 1915, she was placed on thyroid, 1 gr. twice a day. A negative report was received at about this time respecting an X-ray examination of the patient's skull.

September 9th, 1915: Right vision, perception of light; left vision, 3/60. Dose of thyroid increased to 4 gr. a day.

October 7th, 1915: Left vision, 3/60, No. 20 J.

December 4th, 1915: The bright and intelligent girl has a peculiar personal appearance, and is something more than merely well nourished. Her eyes convey the idea of prominence, and the left eye turns slightly outward and upward. Although within a few weeks of 15 years of age, no signs of menstruation have yet made their appearance. No headache, vomiting or vertigo. Pupils 6.5 mm. in diameter. Direct action of the right eye almost lost, while that of the left one is as yet almost intact. A very slow hippus is present. The optic discs are pallid, well-defined, and the physiological cups are not filled in or concealed in any way. Retinal vessels of good size. The visual field of the left eye, as tested for a 10 mm. white square, is entirely confined to the nasal half. The fixation point is as yet intact. Right vision, ? perception of light; left vision, 1/24 (letters) and No. 18 J. (letters).

A report from Dr. Williams, radiographer to the Queen's Hospital, states: "The sella turcica is greatly enlarged, the antero-posterior diameter being 17 mm. There appears also to be some thinning of the clinoid processes."

DR. T. R. WHIPHAM showed two cases of hypertrophic cirrhosis of the liver.

CASE I.—A boy, *æt.* 9, was brought to hospital on Nov. 24th, 1915, with a history of jaundice during the previous three weeks. He vomited at the outset of the jaundice, but had no further nausea until just before he was seen. For the same time he had been getting thinner and had lost his appetite and spirits. The urine had been dark coloured and the motions light "like putty." There was one younger brother in the family, who is healthy, and between him and the patient the mother had had one miscarriage. When first seen the boy was well nourished and presented a general icterus of moderate severity. There was no irritation of the skin and the pulse was not diminished in frequency. The liver was greatly enlarged, extending to within 1½ in. from the umbilicus, and was firm and uniform to the touch. There was no enlargement of the spleen or of the lymphatic glands. The thoracic viscera were normal. A blood count showed red corpuscles 4,500,000, white cells 6,000 per cubic millimetre; the hæmoglobin value was 100 per cent. The urine contained much bile-pigment, and the bowels were constipated. The Wassermann reaction was negative. Treatment with calomel and salines brought about a gradual diminution in the jaundice, and at the present time no coloration was visible. The liver, however, remained approximately the same size.

CASE II.—A boy, *æt.* 6, attended hospital on Jan. 10th, 1916, on account of jaundice of ten days duration. He was said to have been getting thinner and to have lost his appetite. He had had no pain, but had vomited once on Jan. 9th. The urine had been of a dark colour, but, according to the mother's definite statement, bile had never been entirely absent from the stools. The patient has one brother who was healthy and there had been no miscarriages. The boy showed a marked icterus of a deep yellow colour, rather more intense than that in Case I. He had no itching of the skin and the pulse was not slow. The liver was very

similar to that of the first case, but was a trifle larger in proportion, the lower edge being felt within $\frac{3}{4}$ in. from the umbilicus. In this case also there was no enlargement of the spleen nor of the lymphatic glands, nor any abnormality in the thoracic organs. The blood count likewise resembled that in the former case, the red corpuscles numbering 4,500,000 and the leucocytes 10,000 per cubic millimetre, while the hæmoglobin value was also 100 per cent. The urine was deeply pigmented with bile, but the fæces had not been observed. The Wassermann reaction was negative. The patient had been treated with calomel, but the deep jaundice still persisted and the liver had not altered in size.

Dr. J. L. BUNCH showed a case of papillomatous growths in old operation scar.

The boy, æt. 13, was operated on eight years ago for a fatty tumour on the left side of the chest. Some months after the scar had healed, small reddish growths began to appear on and around the scar, and such growths have recurred intermittently ever since. There were now about a dozen of these growths which were soft, sessile and red to purplish in tint. Under the microscope they had a definite papillomatous character, with a well-marked cortex. No tubercle bacilli had been found in them, and von Pirquet's reaction was negative. There was nothing abnormal in the lungs.

Dr. J. L. BUNCH also showed a case of multiple tumours of molluscum contagiosum.

The patient, a girl, æt. 13, had a number of typical molluscum contagiosum tumours on both arms. One or two had undergone degeneration. They had been present about a month.

Dr. J. L. BUNCH also showed a case of chronic patchy dermatitis.

The girl, æt. 11 months, had a number of scattered erythematous patches on the trunk and thighs. These patches appeared soon after birth, the first one being on the side of the neck, and had gradually increased in numbers. No patch which had once made its appearance disappeared again, but after some weeks or months it developed a yellow tint which persisted. No patch was definitely scaly, but some of the earliest ones showed a slight roughness of the skin, the recent patches being quite smooth.

Dr. C. O. HAWTHORNE showed a case of double optic neuritis in a girl, æt. 7. She enjoyed good health until Christmas, when she vomited on two or three occasions in the early morning and before breakfast; also some complaint of headache, but she was never regarded by her mother as in any sense seriously ill. As the vomiting was repeated on several occasions, the doctor advised admission to hospital. She was bright and cheerful, and made little or no complaint; double optic neuritis was marked but there was no other evidence of nervous disease, though a degree of alternating convergent squint; vision 6/6 each eye. Cerebro-spinal fluid negative; Wassermann's test (?). No evidence of visceral disease.

Dr. C. O. HAWTHORNE also showed a case of solid œdema.

The patient, a girl, æt. 15, six years ago fell and cut her left leg below the knee; the limb became red and inflamed and she was confined to bed for a month. Two years later the limb was noticed to be swollen, and this condition had persisted, or even increased, to the present date. There was pitting on pressure over the dorsum of the left foot, and the soft tissues of the left leg and of the lower thigh were thickened but without evidence of dropsy. The left calf had a circumference greater than the right by $2\frac{1}{2}$ in., while 5 in. above the upper border of the patella the left thigh

measured $19\frac{1}{2}$ in., and the right $16\frac{1}{2}$ in. The limbs were of equal length, and skiagrams showed nothing abnormal in the left tibia or fibula.

Dr. THURSFIELD showed a cardiac case for prognosis.

The patient, a girl, æt. 13, had had four attacks of chorea: the first in 1912, the last in May, 1915. She now had her cardiac impulse 1 in. outside the left nipple line with some dilatation of the right side, and systolic and early diastolic murmurs. The chief feature of the case, however, was the pulse irregularity, which varied considerably, but was, according to the electrocardiogram, due to ectopic contractions of the right ventricle. The cardiac affection did not seem to have checked her growth. She now weighed 7st. 11lb. in her clothes, and was unusually muscular and big for her age.

Dr. CAUTLEY showed a case of tumours over manubrium and in left calf in a male infant aged 15 months, whose mother had died 12 months ago from tuberculosis.

Dr. E. C. WILLIAMS showed a specimen heart showing infiltration by large round-celled sarcoma, probably originating in the sternal periosteum, from a boy, æt. 8, with a history of eight weeks' illness, with pain in left side, cough, cyanosis, and orthopnoea. There was an increased area of cardiac dullness, apex beat diffused, sounds muffled, no distinct murmur; later there was friction heard over the sternum, also pleural friction left side.

Post mortem the anterior mediastinum was filled with a white hard growth adherent to the sternum, invading the visceral and parietal layers of the pericardium, rendering them indistinguishable and encasing the heart in a bony hard pericardium. The heart muscle was also invaded. Section of growth by Prof. Walker Hall showed it to be a large round-celled sarcoma.

Dr. ERIC PRITCHARD showed a specimen of congenital double hydro-ureter. Both ureters were greatly enlarged, with double hydronephrosis; at the autopsy they were found to be full of thickly purulent urine. The kidney substance was reduced to a shell, and the ureteral openings of the ureters into the bladder were greatly stenosed. The bladder was enlarged and the walls hypertrophied; the urethral orifice appeared normal.

The patient, a girl, æt. 12, was admitted to the Queen's Hospital for incontinence of urine and ingravescens drowsiness. She appeared to have had good health till within a year of admission, when symptoms of incontinence commenced. Four days before admission pus was discovered in the urine with albuminuria, and the child complained of a sensation of cold down the back. On admission, the child was in a comatose condition, and breathing was slightly stertorous. There was a large, rounded swelling in the abdomen, which extended to the umbilicus. The child had a strong smell of urine and incontinence was continuous. The temperature was normal, the pulse and respirations regular; the blood tension was 125 mm. Hg. The fundi were normal. The urine contained a large amount of pus, with a large number of staphylococci and a few coli bacilli. The uræmic symptoms gradually increased, and the child died four days after admission.

Dr. J. PORTER PARKINSON read a short paper on "Nephritis without Albuminuria following Pneumonia in a Boy, æt. $3\frac{1}{2}$."

A DONATION of 1,000 guineas to endow a bed has been made to the King Edward VII. Hospital, Cardiff, by Messrs. Watts, Watts and Co., coal-owners. The hospital has received four gifts of a like amount from various donors in the past month.

THE NEW LONDON DERMATOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JANUARY 13TH, 1916.

The President, DR. A. EDDOWES, in the Chair.
CASES.

DR. VINRACE exhibited a middle-aged man for diagnosis. He was under care for circinate patches seven years ago. The wife of the patient had tinea circinata on her cheek, and Sir Jonathan Hutchinson ascertained that the husband also had a rash, and that she had probably received the contagion from him. From scrapings submitted, Dr. Wyatt Wingrave concluded that tinea was present. The condition rapidly left the female patient, without leaving any trace; but the man still had an eruption.

The members present were unable to find traces of tinea and thought the rash was becoming lichenised.

DR. SEQUEIRA exhibited a woman patient whom he showed last October as a case of *lupus erythematosus*, so that members could see the result of treatment—viz., 5 grs. ichthyol thrice daily, in capsules. To the face in the daytime had been applied ichthyol ointment, and at night a gutta percha plaster of carbolic and mercury. There had been a very thick crust all round the margin, and very definite infiltration.

Dr. Sequeira was congratulated on the result.

DR. SAMUEL exhibited a woman, who that day had been sent by the gynæcologist at the hospital for diagnosis. The rash broke out after an operation on the genitalia. It was on the chest and back. She had not been taking any drug, or had any injections. He believed it to be *pityriasis rosea*. As she was about to go to a nursing home he was having her blood examined to be sure there was no contagion.

Those who took part in the discussion agreed in the diagnosis and in Dr. Samuel's statement that few such cases had appeared during the last few months.

DR. EDDOWES showed a young woman, a widow, with a rash on the arms and face. She said she would not have thought much of the rash if it had not lately appeared on the face. She stated she had had a symmetrical rash on the arms and hands for five years. It was of deep red colour. The palms looked shiny and dry and somewhat inclined to crack. The rash was sharply defined at the edge, though irregular in outline and slightly scaly, and it itched a good deal. There was a large macular patch on the right side of the mouth, and she had stomatitis. She also had goitre and a very rapid pulse, and was much subject to rheumatism. No other member of the family had had swollen neck. Wassermann reaction was definitely positive. She had one living child, who suffered nervously; she had a bad miscarriage 15 years ago. He thought the eruption on the hands might come into the erythrodermia class; some would call it parapsoriasis, and others a parakeratosis. Bearing in mind the history, it seemed that the whole of her eruption might be syphilitic.

DR. SEQUEIRA considered the case to be specific, because of the definite infiltration. There was very little of the latter in parapsoriasis. He asked whether she had had any antisymphilitic treatment.

DR. SAMUEL said he thought the affection of the hands was chronic dermatitis, not specific. If the latter, it would probably be a late syphilide, and the symmetry was against that idea.

DR. MACK asked whether the affection would

have remained in the same condition for five years if it were a tertiary syphilide.

DR. EDDOWES replied that the patient had not had any treatment for years. He regarded Dr. Mack's question as a very important one. He did not think the lesions would have remained on the hands as they were if due to syphilis only.

DR. VINRACE showed a middle-aged man who had psoriasis on his elbow 17 years ago, and during the last fortnight had developed a very acute outbreak. He did not think he had ever seen a case develop so rapidly. The man believed his mother had psoriasis from 16 to 32 years of age, and that his grandfather, who was still alive, aged 86, had it now. The man said that all the small papules had come out within 24 hours. At times there was violent itching.

DR. SAMUEL said he had seen a few similar cases. They were observed more frequently in children. He was interested in the statement that the condition itched, because patients in whom it came out acutely nearly always complained of itching.

DR. MACK said he remembered seeing a very acute case in which lesions came out nearly all over the body in a week. It was in a child, and was shown before the Royal Society of Medicine.

DR. SAMUEL showed a case of syphilitic disease of the tongue. The patient was a young woman, who presented a condition of the tongue not often seen in the early stages of the disease. She had had a typical secondary body rash. After one intramuscular injection of galyl the tongue had improved a good deal and the rash disappeared. There was neither evidence nor history of a primary sore.

The PRESIDENT asked whether the sore on the tongue might not be the primary lesion; it seemed to be punched-out.

DR. SAMUEL replied that it was difficult for him now to speak dogmatically about the tongue because the ulceration was originally very much deeper than at present.

Other cases were shown, two of them being of special interest:—

1. A case in which the diagnosis lay between *atrophic lichen planus* or a *syphilide*, exhibited by Dr. Samuel.

2. A case of syphilis in which were lesions of an unusual type during the secondary stage, shown by Dr. Vinrace.

LIVERPOOL MEDICAL INSTITUTION.

At the ordinary meeting held on January 27th, the following resolution was proposed by the President (Dr. Charles J. Macalister), seconded by Professor T. R. Glynn, and carried with acclamation:—

"That the congratulations of the members of the Liverpool Medical Institution be tendered to Captain Noel G. Chavasse, R.A.M.C. (T.), 10th (Scottish) Battalion King's Liverpool Regiment, on the occasion of the Military Cross having been conferred upon him by His Majesty the King."

Captain Chavasse is an Associate Member of the Institution.

MR. JAMES HILL, M.P., has marked his unopposed return for the Central Division of Bradford by distributing 1,000 guineas among twelve philanthropic institutions of the city. The Royal Infirmary will receive £400, the Royal Eye and Ear Hospital £100, the Children's Hospital £100, and the Royal Institution for the Blind £50.

SPECIAL REPORTS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

WE are asked by the Registrar of the College to insert the following resolutions concerning the duties of medical practitioners in relation to cases of criminal abortion:—

The College is of opinion—

1. That a moral obligation rests upon every medical practitioner to respect the confidence of his patient; and that without her consent he is not justified in disclosing information obtained in the course of his professional attendance on her.

2. That every medical practitioner who is convinced that criminal abortion has been practised on his patient, should urge her, especially when she is likely to die, to make a statement which may be taken as evidence against the person who has performed the operation, provided always that her chances of recovery are not thereby prejudiced.

3. That in the event of her refusal to make such a statement, he is under no legal obligation (so the College is advised) to take further action, but he should continue to attend the patient to the best of his ability.

4. That before taking any action which may lead to legal proceedings, a medical practitioner will be wise to obtain the best medical and legal advice available, both to ensure that the patient's statement may have value as legal evidence, and to safeguard his own interests, since in the present state of the law there is no certainty that he will be protected against subsequent litigation.

5. That if the patient should die, he should refuse to give a certificate of the cause of death, and should communicate with the Coroner.

The College has been advised to the following effect:—

1. That the medical practitioner is under no legal obligation either to urge the patient to make a statement, or, if she refuses to do so, to take any further action.

2. That when a patient who is dangerously ill consents to give evidence, her statement may be taken in one of the following ways:—

(a) A magistrate may visit her to receive her deposition on oath or affirmation. Even if criminal proceedings have not already been instituted, her deposition will be admissible in evidence in the event of her death provided that reasonable written notice of the intention to take her statement was served on the accused person and he or his legal adviser had full opportunity of cross-examining.

(b) If the patient has an unqualified belief that she will shortly die, and only in these circumstances, her dying declaration will be admissible. Such a declaration may be made to the medical practitioner, or to any other person. It need not be in writing, and if reduced into writing it need not be signed by the patient nor witnessed by any other person, though it is desirable that both should be done, or that, if the patient is unable to sign, she should make her mark. If possible, the declaration should be in the actual words of the patient, and if questions are put, the questions and answers should both be given, but this is not essential. If the declaration cannot there and then be reduced into writing, it is desirable that the person to whom it is made should make a complete note of it as soon as possible.

OBITUARY.

EMERITUS PROFESSOR JOHN WYLLIE, EDINBURGH.

WE regret to have to record the death of Dr. John Wyllie, Emeritus Professor of Medicine in the University of Edinburgh. He took his M.D. with honours in 1865, with a gold medal for his thesis. In the same year he obtained the diploma M.R.C.S.Eng.

After qualifying, he acted as Resident House Surgeon and Physician first in the Edinburgh Royal Infirmary, and then in the Birmingham General Hospital. He was long associated with the Extra-Mural School in Edinburgh, and held the various posts possible to a physician in the Infirmary. His contributions include "The Disorders of Speech," "The Physiology of the Larynx," and various papers in the Edinburgh Hospital reports. He was very highly esteemed as a consultant, and as a clinician he stood in high favour with several generations of students.

DR. WALTER H. B. MACDONALD.

IT was with regret that we noticed the death of Dr. Walter H. MacDonald, R.A.M.C., in Craigleith Hospital, on Saturday, 22nd ult., after a few days' illness, from appendicitis. He was a native of Lochaber, and practically from the year of his graduation, 1888, he has given his life to the Army service. He had the war medal and clasp for Witu, the clasp for Nivele, the Central African medal and clasp for Uganda, etc. He received a letter of thanks, and was presented with a sword by the Sultan of Zanzibar, who also conferred on him the membership of the Order of the Brilliant Star of Zanzibar in 1898. He offered his services at the outbreak of the present war and received a lieutenancy in the R.A.M.C. At the time of his death he was in medical charge of the troops of the Forth defence.

COLONEL C. STONHAM, C.M.G., F.R.C.S., LONDON.

WE regret to announce the death, which took place on 31st January at his residence, 4 Harley Street, London, W., of Colonel Charles Stonham, C.M.G., F.R.C.S., A.M.S., after a severe illness contracted while with the forces in Egypt. Colonel Stonham was aged 57. He was educated at King's School, Canterbury, and University College, London. There he was Aitchison scholar and gold medallist in medicine, obstetric medicine, and surgery. Formerly he was a member of the Board of Examiners in Anatomy, R.C.P. and R.C.S., and was Senior Surgeon at Westminster Hospital. Colonel Stonham, who served in the London Mounted Brigade Field Ambulance, R.A.M.C., was made a C.M.G. for his services in the South African War.

DR. W. D. MURRAY, M.B., C.M., R.A.M.C., LONDON.

THE death has taken place in London of Lieutenant William Dunmore Murray, M.B., C.M., R.A.M.C. Lieutenant Murray, who was 48 years of age, took his medical course at Glasgow University, qualifying M.B., C.M. in 1889, and afterwards proceeded to London, where he had been in practice in Clapham. On the outbreak of war he relinquished his practice to join the R.A.M.C., and he had been stationed at Colchester as a member of one of the Examining Boards. He is survived by his widow and two sons. His eldest son is at the front with the Northumberland Fusiliers.

NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publication of our last monthly list:—

- BAILLIERE, TINDALL AND COX (London).
Manual of Anatomy: Systematic and Practical. Including Embryology. By A. M. Buchanan, M.A., M.D., etc., etc. Third edition. Illustrated. Pp. 1,743. Price 21s.
Rhizopod Protozoa: The Cause of Cancer and other Diseases. Being Part IV. of "Protozoa and Disease." By J. Jackson Clarke, M.B.Lond., F.R.C.S. Pp. 187. Price 7s. 6d.
Sleeping Sickness. A record of four years' war against it in Principe, Portuguese West Africa. By B. F. Bruto Da Costa, J. Firmino Sant' Anna, A. Correia Dos Santos and M. G. De Coranjo Alvares. Published in Portuguese in "Archivos de Hygiene E Pathologia Exoticoas." Vol V., March 30th, 1915. Translated by permission of the Lisbon School of Tropical Medicine. By J. A. Wyllie, F.R.G.S. (Three-coloured maps.) Pp. 260. Price 7s. 6d.
A Manual of Surgical Anaesthesia. By H. Bellamy Gardner, M.R.C.S., M.R.C.P.Lond. Second edition. Illustrated. Pp. 220. Price 7s. 6d.
BALE, SONS AND DANIELSSON, LTD. (JOHN) (London).
The Triangular Bandage. By Howard M. Preston. With introduction by James Cantlie, M.A., M.B., etc., etc. Pp. 62. Price 1s.

- CHURCHILL, J. AND A. (London).**
 Southall's Organic Materia Medica. Eighth edition. Revised and enlarged by Ernest W. Mann, B.Sc.Lond., F.I.C. Pp. 390. Price 7s. 6d.
- St. Thomas's Hospital Reports. New Series. Edited by J. J. Perkins and C. A. Ballance. Vol. XLII. Pp. 205. Price 8s. 6d.
- The Primary Lung Forms of Tuberculosis in Children. By Dr. Athou Ghon. English edition. Translated by D. Barty King, M.D. Pp. 172. Price 10s. 6d.
- A Code of Rules for the Prevention of Infectious Diseases in Schools. Issued by The Medical Officers of Schools Association. Seventh edition. Pp. 52. Price 1s.
- PROWSE, H.R., AND HODDER AND STOUGHTON (London).**
 Medical Lectures and Aphorisms. By Samuel Gee, M.D. With recollections by J. Wickham Legg. Pp. 408. Price 6s.
- A Manual of Surgical Anatomy. By Lewis Beesley, F.R.C.S. Edin., and T. B. Johnston, M.B., Ch.B. Pp. 557. Price 12s. 6d.
- Handbook of Massage for Beginners. By L. L. Despard. Pp. 247. Price 6s.
- Diseases of the Throat, Nose and Ear. By William H. Kelson, M.D., B.S., F.R.C.S.Eng. Pp. 270. Price 8s. 6d.
- HAZELL, WATSON AND VINET, LTD (London).**
 Hazell's Annual for the Year 1916. Edited by T. A. Ingram, M.A., LL.D. Pp. 623. Price 3s. 6d.
- HEMPHREY MILFORD (Oxford University Press) (London).**
 The Cures of the Diseases in Foraine attempts of the English Nation. London 1598. Reproduced in facsimile, with introduction and notes by Charles Singer. Price 1s. 6d.
- The Pathology and Treatment of the So-called Nervous Asthma. By J. B. Berkart, M.D. Pp. 54. Price 2s. 6d.
- KIMPTON, HENRY (London).**
 Notes on Military Orthopaedics. By Paul Bernard Roth, M.B., F.R.C.S. Illustrated. Pp. 56. Price 1s.
- LEWIS, H. K., AND Co., LTD. (London).**
 Amnesia and Analgesia in Parturition (Twilight Sleep). By Alfred M. Hellman, B.A., M.D., F.R.C.S. Pp. 197. Price 6s. 6d.
- LIVINGSTONE, E. and S. (Edinburgh).**
 Wheeler's Handbook of Medicine. By William R. Jack, B.Sc., M.D., F.R.F.P.S.G. Fifth edition. Pp. 552. Price 8s. net.
- Back Injuries and Their Significance under the Workmen's Compensation and Other Acts. By Archibald McKendrick, F.R.C.S.E., etc. Pp. 173. Price 2s. 6d.
- LONGMANS, GREEN AND Co. (London).**
 In a French Military Hospital. By Dorothy Cator. Pp. 99. Price 2s. 6d.
- LIPPINCOTT, J. B., Co. (London).**
 Simplified Infant Feeding. By Roger H. Dennett, B.S., M.D. Illustrated. Pp. 355. Price 13s. 6d.
- MACMILLAN AND Co., LTD. (London).**
 Diseases of Nutrition and Infant Feeding. By John Lovett Morse, A.M., M.D., and Fritz B. Talbot, A.B., M.D., Pp. 246. Price 10s. 6d.
- "PRESCRIBER, THE." Offices (Edinburgh).
 Incompatibility of Prescriptions and How to Avoid It. By Thomas Stephenson, Ph.C., F.R.C.S. Pp. 32. Price 1s. net.
- PUTNAM, G. P., AND SONS (New York and London).**
 A Quiz Book of Nursing. By Amy Elizabeth Pope and Thirza A. Pope. Pp. 482. Price 7s. 6d.
- Text Book of Anatomy and Physiology for Nurses. By Amy E. Pope. Pp. 596. Price 7s. 6d.
- THACKER, SPINK AND Co. (Calcutta).**
 Tropical Hygiene for Residents in Tropical and Sub-Tropical Climates. By the Hon. Surg.-Gen. Sir Purdey Lukis, R.C.S.L. V.D., and Lt.-Col. R. J. Blackham, C.I.E., R.A.M.C. Third edition. Revised and enlarged. Pp. 302. Price 3s.
- WHITAKER'S ALMANAC (London).**
 Whitaker's Almanac, 1916. Pp. 858. Price 2s. 6d.

It was resolved to form an investment reserve and to place to this account a sufficient sum to meet the depreciation in stock values. It is pleasing to report that this only amounts to £4,000.

The date of the annual meeting of the members was fixed for March 28th, and a notice to this effect was ordered to be placed in various medical journals.

L.C.C. Asylum at Epsom.

At a meeting of the London County Council on January 25th, the Asylums Committee reported that the Treasury had intimated that they were not prepared to approve of the continuance of the expenditure for the erection of the eleventh county asylum at Epsom. Steps had accordingly been taken to stop work on the buildings as early as possible. This had involved coming to terms with the contractors and the payment of £16,000 compensation for suspension of work. The work would be resumed one year after the declaration of peace, or earlier by arrangement.

It was stated that three-quarters of the building was already finished. Now it was costing the rate-payers £16,000 to get rid of a contract, and they would still have to find accommodation for the patients. This would cost far more than if the asylum was proceeded with until it was finished, which would have been in about nine months' time. If necessary, the Government could then have used it as a military hospital.

It was further observed that the report was not brought forward as an economical proposition. The Treasury was prepared to exercise the power they had to stop them paying for the work, on the ground that every pound of capital was wanted for the war. It was obvious that if the Council's capital was expended on the asylum the Treasury could not have it. The building was not suitable for hospital purposes.

The Council approved the report.

Infectious Diseases in Aberdeen.

The following is the return of cases of zymotic disease notified to the Medical Officer of Health for Aberdeen for the week ending Saturday, January 22nd, 1916:—Scarlet fever, 31; whooping-cough, 8; chicken-pox, 3; erysipelas, 1; puerperal fever, 2; pulmonary tuberculosis, 8; other tuberculosis, 2. Of the 64 cases thus notified, 36 cases, including 1 case of tuberculosis, are being treated within the City Hospital or other public institution.

Medical Students as Recruits.

In the House of Commons, on January 24th, Sir G. Parker asked the Under-Secretary for War if he would state what was the policy of the Government in regard to first and second year medical students in the field of recruiting; was he aware that an applicant had been refused by a responsible organisation, such as the Inns of Court Officers' Training Corps, on the ground that the applicant was a medical; was he aware that medical students who were willing to serve either as medical men or as soldiers were in a position of uncertainty and instability; and, if so, what was the course to be pursued in regard to this class?

Mr. Tennant replied: There has been no change in the policy regarding the first and second year students. I have frequently stated it in this House. The case referred to in the latter part of the question has not been brought to my notice. I may add that it is not contemplated that qualified medical men should be used as soldiers in the ranks.

In Aid of the Red Cross.

MR. JOHN S. SARGENT has supplied a design for a Red Cross envelope which will shortly be on sale for the benefit of the funds of the Society. The design is every effective. The drawing shows two classic figures, one of a soldier, wounded but triumphant, being raised from a stretcher by the other, a nurse, and both are set white against the silhouette of a large red cross.

THE Rev. E. M. Griffin, British Red Cross Hospital, Saideh School, Giza, Egypt, asks for table games, puzzles, and billiard balls for the patients.

MEDICAL NEWS IN BRIEF.

Medical Sickness and Accident Society.

At the ordinary monthly meeting of the Executive Committee of this Society, Dr. F. J. Allan in the chair, it was found that the sickness claims for the month were up to expectation, but that for the whole year the total experience was below total expectation, and this notwithstanding that a large sum was paid to members invalidated home from active service, a quite unusual risk and one not provided for in the tables on which the sickness expectation was based. The new proposals received were fewer in number than for the same month in the preceding year, and, in common with most insurance companies, it is not anticipated that this branch will show high figures in the coming year.

The figures for proposals for more sickness benefit from existing members continue to show good returns. The increase in the cost of locum appears to account for this to some extent.

The society still accepts members of the R.A.M.C. for limited amounts in sickness benefit and life assurance without extra premium.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

REPRINTS—CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

REPRINTS—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer not necessarily for publication, but as evidence of identity.

ISLINGTON'S LOW BIRTH RATE.

DR. A. E. HARRIS, medical officer of health for Islington, reports that in the fourth quarter of last year the birth-rate fell to 21.65 per 1,000 inhabitants, the lowest rate hitherto recorded, the average for the corresponding ten years being 24.52.

A QUIANT WILL.

SURGEON-MAJOR JOHN O'LEARY, I.M.S., of Curryhevern, Timoleague, co. Cork, who died at Ismailia, Egypt, on September 9th last, has left personal property of the value of £2,912. The testator gives £100 to his godson, "Blest if I can remember his Christian name, but I think it is Jas" Fitzpatrick, legacies to other relatives, and the residue, "after Lloyd George's death duties and the lawyer's death duties have taken their little bit," to his sister Margaret, desiring her to give some to the poor "some deserving and some not" who lived near us.

SATISFACTORY FOR BOTH.

SERGEANT (at recruiting office, cynically to recruit): "Come to join, eh? For the separation allowance, I suppose?"

RECRUIT: "Yes, sir! I want the separation and she wants the allowance."—*The Bystander*.

THE CINEMA AND SCARLATINA.

In a report to the Dover Health Committee on a serious outbreak of scarlet fever, Dr. Gibson, assistant medical officer, states that he has traced many cases to cinema halls. He considered this to be due to the continuous darkness of the hall.

L. S. A. (Barking).—It is several years since the nomenclature was altered.

SECTION (Glasgow).—The book was reviewed in our columns two months ago.

DR. J. B. (Oxford).—We are writing you direct.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 2ND.

ROYAL SOCIETY OF MEDICINE (SECTION OF SURGERY) (1, Wimpole Street).—5.30 p.m.; Paper and Demonstration. Dr. F. Hernaman-Johnson: The Use of Condensers in the Diagnosis, Prognosis, and Treatment of Nerve Lesions. N.B.—Members of the Sections of Medicine, Neurology, and Electro-Therapeutics are specially invited to attend.

ROYAL SOCIETY OF MEDICINE (SECTION OF OPHTHALMOLOGY) (1, Wimpole Street, W.).—8.30 p.m.: Papers. The Cause of the Ophthalmoscopic Appearances in Amaurotic Family Idiocy: By the late Mr. George Coats (to be read by Mr. R. Affleck Greeves). Mr. Holmes Spicer: Superficial Linear Keratitis. Short Communication.—Mr. Walter Edmunds: Cataract in Experimental Thyroidectomy. Cases.—Mr. J. Herbert Fisher: Arterio-venous Aneurysm. Mr. Harold Grimsdale: Dilated Retinal Vessels; and other Cases.

ROYAL SOCIETY OF ARTS (John Street, Adelphi, W.C.).—4.30 p.m.: Paper. Hon. Lady Parsons: Women's Work During and After the War.

THURSDAY, FEBRUARY 3RD.

ROYAL SOCIETY OF MEDICINE (SECTION OF OBSTETRICS AND GYNECOLOGY) (1, Wimpole Street, W.).—8 p.m.: Specimens. Dr. Herbert Spencer and Dr. E. A. Barton: Speculum-camera. Dr. Herbert Spencer: (1) Tubular Needle for Silver Wire; (2) Needle-holder for Pelvic Work. Short Communications.—Dr. Walter Salisbury: Three Cases of Labour obstructed by Ovarian Cyst. Dr. Francis M. Huxley: Fatal Rupture of Bladder in the Puerperium. Dr. M. Handfield-Jones: Chorion Epithelioma following Vesicular Mole. Paper.—A discussion on the "Clinical Aspect of the Double Uterus" will be introduced by the President, Dr. M. Handfield-Jones.

FRIDAY, FEBRUARY 4TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF LARYNGOLOGY) (1, Wimpole Street, W.).—4 p.m.: Cases. Will be shown by Dr. Dan McKenzie, Dr. Edmond, Mr. Lambert Lack, Dr. Stuart-Low, and others.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith Road, W.).—8 p.m.: Pathological Meeting. Specimens will be shown by Major McAdam Eccles, Dr. A. Saunders, Mr. N. B. Harman, Dr. R. Morton, Dr. H. J. Banks Davis, Dr. Bernstein, Mr. Gray, Mr. Souttar, and others.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Hunterian Lecture. Sir John Bland-Sutton: New Ulcers for Old—Jejunal for Duodenal Ulcers.

MONDAY, FEBRUARY 7TH.

MEDICAL SOCIETY OF LONDON.—9 p.m.: The first Lettsomian lecture will be delivered on "The Effects of High Explosives on the Central Nervous System." By Major Fred W. Mott, M.D.Lond., Hon. LL.D.Edin., F.R.S.

Vacancies.

Bury Infirmary.—Senior House Surgeon. Salary £250 per annum, with board, residence, and washing. Applications to the Hon. Sec., Infirmary, Bury, Lancs.

Borough Hospital, Birkenhead.—Junior House Surgeon. Salary £170 per annum, with board and laundry. Applications to the Secretary.

Leeds Public Dispensary.—Lady Resident Medical Officer. Salary £130 per annum, with board, residence, and laundry. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

Bridgwater Hospital.—House Surgeon. Salary £125 per annum, with board, lodging, and washing. Applications to Edward Trevor, Hon. Sec., Bank Chambers, Bridgwater.

Manchester Northern Hospital for Women and Children, Park Place, Cheetham Hill Road, Manchester.—Lady House Surgeon. Salary £120 per annum, with apartments and board. Applications to Mr. Hubert Teague, Secretary, 35, Barton Arcade, Manchester.

Birmingham and Midland Eye Hospital, Church Street, Birmingham.—House Surgeon. Salary £200 per annum, residence and board. Applications to J. W. Pearce, General Supt. and Secretary.

Appointments.

HUEY, J. M., M.B., Ch.B.Glas., Certifying Factory Surgeon for the Millom District, co. Cumberland.

MURPHY, Geraldine, M.B., B.Ch., B.A.O.Dub., House Physician to the Chester Royal Infirmary.

NASH, Miss Amy F., F.R.C.S.I., House Surgeon to the Chester Royal Infirmary.

Births.

CROSS.—On January 21st, the wife of Dr. H. R. Cross, Storthes Hall Asylum, Kirkburton, near Huddersfield, of a son.

FISHER.—On January 24th, at Shoreditch Infirmary, London, North, to Dr. and Mrs. Fisher, a boy (Adrian Welby).

HALL.—On January 24th, 1916, at The White House, Eastbourne, the wife of E. Wilson Hall, M.R.C.S., L.R.C.P., a daughter.

LOCK.—On January 24th, at Herschel House, Cambridge, the wife of Norman F. Lock, M.A., M.B., F.R.C.S., Lieut., R.A.M.C., of Boston, Lines, a son.

MACFADDEN.—On January 26th, at 20, Lymington Road, Hampstead, N.W., the wife of Arthur W. J. MacFadden, C.B., M.B., of a son.

RAMBAUT.—On January 25th, at Priory Cottage, St. Andrew's Hospital, Northampton, the wife of Daniel F. Rambaut, M.D., of a son.

STEWART.—On January 24th, at "Wiggenhall," Sevenoaks, the wife of Captain W. J. Stewart, R.A.M.C., a daughter.

Marriages.

EDMUNDS—BROWN.—On January 29th, at King's Heath Parish Church, Surgeon W. H. Edmunds, R.N., to Dorothy Margaret, daughter of the late Mr. and Mrs. Herbert Brown, and sister of Harry S. Brown, 3, Valentine Road, King's Heath.

HAMPSON—FINNEMORE.—On January 28th, at All Saints' Church Four Oaks, Capt. Travis Hampson, M.B., R.A.M.C., S.R., elder son of Mr. and Mrs. W. Hampson, Lake Wyrnwy, Oswestry, to Alice Mary, youngest daughter of the late Alfred Finnemore and Mrs. Finnemore, of Chesterton, Four Oaks.

SUTHERLAND—THOMSON.—On January 26th, by special licence, at St. Catherine's Parish Church, Merstham, Surrey, Major Donald Sage Sutherland, M.D. (Glas.), R.A.M.C.T., 1st City of London Field Ambulance, eldest son of the late Rev. Donald Sutherland, Rossie Lodge, Inverness, to Louise Mary Thomson, youngest daughter of Albert Sudbury Thomson.

WATT—GARLE-BROWNE.—On January 25th, at Westminster Cathedral, James Watt, M.A., M.B., D.P.H. (Aberd.), to Dorothy Muriel, elder daughter of the late John Garle-Browne, Esq., Bufton Lodge, Desford, Leicestershire.

Deaths.

CARTER.—On January 24th, at Marden Ash, Ongar, Surg.-Major Frederick Carter, I.M.S., in his 86th year.

CLARK.—On January 23rd, at Bulawayo, Rhodesia, William Gladstone Clark, M.A.Cantab., F.R.C.S., aged 49 years.

GARROD.—Killed by shell in France, on January 26th. Alfred Noel Garrod, M.R.C.S., Lieut., R.A.M.C., 100th Field Ambulance, eldest son of Archibald E. Garrod, M.D., F.R.S., Colonel, A.M.S., and Mrs. Garrod, of 9, Chandos Street, W., and Wildford Lodge, Melton, Suffolk, aged 28.

KIRKWOOD.—On January 30th, at 1, North Street, Peterborough, George Kirkwood, M.D., aged 63 years.

LOVELL.—On January 28th, at 62, Holmdale Road, West Hampstead, Francis Henry Lovell, Kt., C.M.G., F.R.C.S., LL.D., in his 72nd year.

SANDERSON.—On January 23rd, at Joannville, Jersey, Colonel Arthur Sanderson, R.A.M.C., in his 82nd year.

STONHAM.—On January 31st, at 4, Harley Street, Colonel Charles Stonham, C.M.G., F.R.C.S., A.M.S., after a severe illness contracted while serving with the Forces in Egypt.

WHITE.—On January 27th, Thomas Henry White, Lt.-Colonel R.A.M.C., of "Coolgardie," Caversham, in his 79th year.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, FEBRUARY 9, 1916.

No. 6.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravants les méchants, je me hâte de rive de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

In a letter to a correspondent, which appeared last week in the daily Press, Lord Derby gives reasons for the further medical examination of those already rejected on medical grounds. The first of these reasons is a confession; the second is amusing; the third is conclusive. Here is the first: "Many men slipped through during the recent rush, and it would be unfair that men who are not entitled should wear an armlet on the strength of a medical certificate obtained without adequate examination." From all accounts the "slipping through" was done, not by the fit into freedom, but by the unfit into the ranks. The examining officers certainly have not erred on the side of lenity, with the result, as has so often been pointed out, that many men have been enrolled who are now a financial burden upon the taxpayer, and are likely to remain so. If it be the case that any slackers have escaped enlistment, then by all means let them be caught. It is nevertheless to be feared that any access or excess of zeal will only result in adding to the list of the uniformed unfit.

The second reason displays a certain ingenuity on the part of the physically disabled which must have required considerable astuteness to detect.

Rejection Papers.

"Again, cases are known where a man suffering from some permanent physical disability obtained a medical rejection paper, and then went to various recruiting offices and obtained further rejection papers, giving names of friends, to whom he sold the rejection papers. This practice was stopped by having the registration card stamped by the recruiting officer, but there are a certain number of these bogus rejection papers in existence." It is to be hoped that some, at any rate, of these vendors have been successfully laid by the heels, and that every one of the purchasers will be duly drawn into the net. The latter deserve punishment as much for their stupidity as for their lying cowardice. Having regard to the wide advertisement given to the way out via "conscientious objection," what on earth can be the object of partici-

pating in a fraud? A little snuffing cant is all that is necessary: it is much cheaper and much less risky than the purchase of a bogus rejection paper.

Conclusive.

The third reason is really all that was necessary to convince any thinking person. Here it is: "A further reason is that, the standard having been considerably lowered recently for certain branches of the Army, many men who were formerly rejected are now required. Men who are physically fit can be released from clerical duties and replaced by men only fit for sedentary occupations. For example, a man with a cork leg would be quite unfit for active service; but, if he be a trained and experienced clerk, might be very, very useful indeed in a pay department, and could release a more active man for foreign service." That is quite reasonable; but, if this is true of the physically unfit, it also applies to the conscientious objector. There is evidently plenty of work for the latter to do without exposing his precious skin either to shrapnel or to the vaccination lancet. Why in the name of common justice and common sense is he not made to do it?

An Experience.

That the medical examinations in the past have not always been free from serious reproach is notorious. The experience of a correspondent of the *Manchester Guardian* is worth quoting. It is by no means unique. "I was rejected in November on two counts, both stated to be remediable only by operation. On January 17th I applied for my armlet as a 'reject.' I was told I must be re-examined. I agreed; was taken very hurriedly in a batch of six, and, after a most cursory examination, was certified fit for general service, with a clean bill of health. I mentioned the causes of the previous rejection, but was dismissed with the statement that I was 'not suffering from them now.' As I am about to be operated on for one of the defects which I am officially stated not to have, and as the other, of course, remains, the verdict, though cheerful, is somewhat grotesque. And since such carelessness in examination may obviously, in some cases, result in needless confusion and even in grave injustice, it may be worth exposing."

I SEE it stated in the *The Times* that in the matter of eyesight tests "the Army Sight Standard. Army standards have often been called in question and nearly always in an ignorant manner." So

far as the MEDICAL PRESS AND CIRCULAR is concerned, the adverse comments on the present tests have been addressed to us by some of the leading authorities, who have explained their reasons at considerable length and in such a manner as to carry conviction to anyone with any knowledge of the subject. (a) The writer in *The Times* goes on to say: "The question at issue is not whether a doctor thinks a man should be able to see this object or that, but whether he is actually capable of seeing distant objects which commanding and other officers demand that he shall be able to see. A moment's consideration of the work of artillerymen will reveal the obvious character of this requirement." This is quite true, and it is purely on utilitarian grounds that the present tests are condemned.

IN the next paragraph the writer is a little out of his depth: "These the Ophthalmological Society. true, been translated into medical terms and language. This was necessary. The work was undertaken by the Ophthalmological Society some time ago at the suggestion of Sir Alfred Keogh himself. The standards in use have therefore a double sanction, and no fears need be entertained either that they are not adequate or that they will not be applied justly and thoroughly." Now, the Ophthalmological Society appointed a committee in 1886 to advise the War Office on this question, and it is to be supposed that the recommendations of the former were adopted by the latter. But for the last thirty years the Ophthalmological Society has not moved in the matter, and it is very doubtful if it has ever been approached. The writer is mistaken in supposing that Sir Alfred Keogh has consulted the Society. Had he done so, there is not the slightest doubt that the peace-time tests, which were still operative after a year's war, would have undergone very drastic revision.

In a Nutshell.

THE whole question really resolves itself into this: Ought soldiers, either officers or men, to be allowed to wear glasses? The principle is the same in every army, and if the answer to such a question is in the negative, as in the case of the British Army it hitherto has been, then it is obvious that the German Army is working on a wrong principle. Glasses are admittedly a great inconvenience, but a man who sees well with glasses is obviously better than a man with defective eyesight who has no glasses. The British standards used to admit men of the latter class while refusing many who with the aid of suitable correction had perfectly normal vision. The correspondence to which I have already referred

brought this point into great prominence. If it be granted that the exigencies of active warfare demand that glasses shall be allowed, then it matters nothing what the ocular defect is, provided that suitable correction ensures normal vision. That is evidently the principle which obtains both in France and Germany, even in times of peace.

Khaki Again.

ALTHOUGH, in deference to the friendly protest of a correspondent, I have agreed, myself, to give this subject a rest, I cannot refrain from publishing the following, which comes from the North:—"What need is there for the part-timers, serving in the military hospitals, to wear uniform? I have heard no reason given in its favour that is not foolish. A uniform is an assemblage of dry goods that needs to be lived up to, and the liver must be caught young. Some of our leading physicians and surgeons, decent lads, were by no means young when caught by the authorities and pushed into khaki. The combination is striking in some cases: think of a gentleman with Glasgow legs, of mixed calliper and Chippendale pattern, in khaki—or in kilts. And the beards—that the wives defy them to shave—wagging over tunics and Sam Brown belts, "bedropp'd wi' crimson hail!" (tomato soup). It's fair sickening. Some have tried living up, or down, to the "military" in their mode of speech. Instead of gude Gallowgate or worse Ke-elvinside, it shows itself in the Englishish, nippity clippity style of speech beloved of our officers, whose words are few and well-chosen. "Rotten," "ripping," "swank," "blighters," "rations" to rhyme with "nations," and "wash-out"—these are the working words; others are not needed much."

The Reason Why.

"Now, why were these gentlemen put into disguise? They were not consulted: they did not want to wear uniform when they were mobilised (fine word that!): it was not for discipline's sake. No, the reason lies deeper. It belongs to the time when the army was just a handful, and form was of much greater importance than matter; because those in authority had nothing else to do but look after such things. And these same gentlemen need not complain of the vast amount of needless writing and signing of sheets for each patient they take care of, for that is of the same origin. At one time in the War Office there was a man who was piously brought up and believed with Dr. Watts that mischief was found "for idle hands to do." And so he invented these diet sheets, case sheets, diagnosis sheets, passes *et hac omnia* to prevent the young medicos in our small army from falling into mischief. And it succeeded, no doubt. Now, in the midst of the real thing this clerical work is irritatingly ridiculous. You have to state on which side you operate for appendicitis."

Raids, Chimes and Whistles. AN official announcement says "The police are advised by the War Office and Admiralty that during the war the use of the chimes and the striking of public clocks should be discontinued between

(a) See Mr. Ernest Clarke's letter which appeared in our issue of June 16th, 1915, page 596.

sunset and sunrise." It is to be presumed that the prohibition has some connection with air raids, and is doubtless a wise precaution. If that is the case, if chimes and public clocks are calculated to give information to the enemy, why not cab-whistles? Chimes and public clocks tinkle their information from various parts of the country, even from remote villages, whereas the cab-whistle is confined to London. An air-raider hearing one of these piercing abominations would at any rate know that he was over a certain part of the metropolis, a piece of precious information which he could never glean from a chime or a clock. To stop a chime during certain hours of the night only, in the case of most clocks, must present a mechanical difficulty, whereas the outrage of cab-whistles could be abolished by a stroke of the pen. Why is it not done?

Those Bells.

FROM the point of view of the ordinary citizen in peace-time, public clocks and their chimes are not only unobjectionable; to the sleepless they are even companionable. The same

cannot, however, be said of church bells. These usually begin their insistent cymballing at an hour when the restless, the wakeful and the feverish are at length on the point of reaching that peaceful, necessary sleep for which they have been longing. But they are not to have it. - The charitable Church authorities ordain that for another half-hour these unfortunates are to be stretched on the rack, and at the end of that time the call to sleep has gone. The tolling of the church bell is said to have originated in the belief that the Devil could thus be frightened away from the sacred precincts. It was at a much later date that the bell was used for the purpose of calling the clockless faithful to prayer. In country districts the bell may still serve a useful purpose, but in large towns it is an irritating anachronism which ought to be abolished. A beginning might well be made by preventing any and every newly-erected tin tabernacle from inflicting its peevish cacophony upon an already sufficiently suffering neighbourhood.

ABOUT the middle of last month a resolution was moved in the House "Undesirables." of Commons to exempt from ordinary military service "all fully qualified medical practitioners or registered dentists." Mr. Walter Long resisted the resolution, while paying a high tribute to the work of the profession of whose interests he is a well-known and much-appreciated supporter. The reason of his opposition was that the resolution would enable persons who are "undesirable members of the profession" to escape service of any sort; and he went on to point out that any members of the profession who were roped in to the purely combatant ring could obtain exemption from the Tribunal. This seems to me to be very unsatisfactory. It means that a medical man or a dentist who becomes a combatant would, from this very fact, lie under the suspicion, amount-

ing indeed to a practical certainty, that he had been branded by the Tribunal as an undesirable member of his profession. It is by no means clear how these Tribunals are to be constituted, except that labour and femininity are to be adequately represented. If the law is to stand as outlined above, the members of the profession should see to it that their interests are locally in the hands of sympathetic, educated men who have some knowledge of professional matters. To be officially adjudged "an undesirable" by two labourers, a suffragette, and, perchance, an anti-vivisectionist, would not be amusing.

The Pedestrian Peril.

NEW Scotland Yard is appealing to the public for information concerning two deaths, both of them believed to have been caused by motor-cars. One is that of a young woman, who was knocked down by a car at New Malden; the other, that of an elderly man found unconscious in St. Mary's Street, Kensington. The first occurred at 10.25 p.m., the other at 9.5 p.m., and they were thus both obviously caused by the combination of darkened streets and rapid driving. The only wonder is that such accidents are not more frequent than they are. It is a positive scandal that 'buses and other heavy vehicles whose impact, even when moving slowly, means almost certain death, should be allowed to career at a break-neck pace along the darkened and slippery streets. People are apt to forget that the force of such an impact is the pace multiplied by the weight, and that these four-wheeled monsters are consequently a deadly peril to anyone who is unfortunate enough to come into contact with them. Restrictions as to the rate of driving which are in accordance with the altered lighting conditions are urgently required. They ought to be enforced at once, and any infringement of them should be very severely punished.

Zeps. and Tubercle.

THE old maiden lady from the North who believed in love "in the abstract" finds her counterpart to-day in hundreds whose faith in the open window is of the same cautious quality. The stringent regulations for darkened lights leads to drawn blinds; and drawn blinds, lest they flap, bring the closed window in their train. This is disheartening to those vigorous campaigners against tuberculosis who for some dozen years past have been carrying the icy cross of the open window throughout the length and breadth of the land; for there is no doubt that a great many stay-at-homes will find in the lighting regulations an excuse for a lapse from grace which will continue long after the cause has ceased to be operative. As a set-off against this, there is the undoubted fact that the open-air method which military training entails will engender in many a taste for these methods, which they will insist upon gratifying when, from the trenches, they return to the stuffiness of civilian quarters. In the long run, therefore, the open window stands to win; but in the meantime the fear of the Zep. is the promoter of tubercle.

A friend writes:—

Glasgow University. "THE Final Year Dinner of the Medical School at Glasgow University is always an interesting function, especially to the graduands. To guests also, particularly if they have arrived at the age and stage of being '*laudatores temporis acti.*' For they are very apt to say to themselves, pensive in their looking backwards, 'This is all very well, but nothing to what it was in Our Year!' This year's meeting, held on the 26th ult., under the chairmanship of the genial Professor of Midwifery, was of interest to all. One new turn, carbon-sketching of hospital events, executed by one of the students, was very clever. But withal there was an unusual staidness, quite unlike the evenings of long ago, for the cloud of the war was over it all. Though there was a seeming brightening up of the crowd by the touches of colour throughout the room introduced by the uniforms of members of both services, yet there was, as was natural, a feeling of repression, an absence of the gaiety that accompanied the function in past years. It would seem that the quiet, self-effacing manner of the students who had been to the front, referred to by Professor Muir, had been reflected on those who were yet to go."

Obesity and Disease.

THE article which we publish this week from the the pen of Dr. Parkes Weber on one aspect of obesity is an important one to every medical man who acts as a referee to an insurance company. The subject of obesity in general, except in so far as the fatness was the result of gross feeding, had been the cause of much puzzlement to observers until its relation to disturbances of the ductless glands came to be thoroughly appreciated. There can be no doubt that, viewed in this connection, over-fatness ceases to be a subject for jocularly and immediately becomes one for prospective and prognostic anxiety. Myxœdema is not obesity; to the seeing eye it is a caricature of obesity. Nor can any careful observer fail to note the differences between the results of too much food and those of the disturbance of the pituitary known as Froelich's Syndrome or, as Jonathan Hutchinson called it, Lipomatosis Universalis Asexualis. Even the question of overfeeding, which, ever since the time of Banting, has been expressed in terms of relative carbohydrate overfeeding, is to-day recognised as a function of the ductless glands; for it is these mysterious organs which regulate the carbohydrate tolerance of the individual. Dr. Parkes Weber's article is full of interest and instruction for those who would have to estimate the bearing of what, for want of a better term, we must still call obesity.

SINAPIS.

Health of Cotton Workers.

THE quarterly report of the Darwen Weavers', Winders' and Warpers' Association throws an interesting light on the mortality figures as they affect this particular industry. During the period named ten members have died, whose united ages total 601 years, the average age being 60 years 36 days. The eldest (a female) tops the list at 83, whilst the youngest (also a female) is 37. There are other three women whose respective ages are given as 69, 68, and 66. The oldest male member is 65.

CURRENT TOPICS.

Schools for Physically Defective Children.

IN our present issue we publish a valuable article by Dr. W. A. Winter, dealing with the provision of schools for physically defective children. In the ordinary way the child who is physically defective or invalid will probably not be sent to school. It is suffered to grow up without any mental training or education, and without any chance of earning a living, if, as is likely, its physical defects prevent its undertaking manual work. To such a child there is no prospect but one of continuous dependence. This is all the more deplorable since it frequently happens that a child who is physically defective may be specially bright mentally. Up to the present little attention has been paid to these children, and for the most part they have drifted from the hospital to the workhouse. It is greatly to the credit of the Education Committee of the London County Council that the problem has been tackled, and that some two dozen special schools have been established in London to deal with this class of pupils. These schools have been very successful, and we hope to see the example of London followed in other parts of the Kingdom, though we recognise that the present is not a time when public authorities are likely to embark on new undertakings.

Import of Fruit.

IT is with considerable regret that we note that fruit is among the articles whose importation the Government has decided to limit. Of late years fruit has come to take a more and more prominent part in the diet of the people of these countries. From being regarded as something of a luxury it has become a regular article of diet. This is all for the good, and we would like, in the interests of health, to see fruit used more widely still. We know many people who take it with advantage at every meal, and whose health will certainly suffer if they have to forgo its use. Every physician of experience will agree with our view as to its high value in keeping the teeth and mouth clean, in stimulating the flow of digestive juices, and in promoting a regular action of the bowels. We therefore feel deep regret that the Government has thought it necessary to take a step which is likely to render fruit to a great extent inaccessible for people who cannot afford luxuries. We cannot help thinking that in including fruit in their list of articles whose import is to be limited, the advisers of the Government have had some hazy notion that fruit is merely a luxury. We do not regard it as such, and we cannot help contrasting, as we note the *Spectator* does this week, the attitude of the Government toward apples and oranges and bananas with its decision not to limit the import of sugar and barley and other materials used in the manufacture of alcoholic drinks.

The Compulsory Notification of Measles.

AT a meeting of Bristol Health Committee held on February 1st, Dr. Davies, Medical Officer of Health for the City, presented a special report on

the notification of measles (recently made compulsory) and the increased burden which it will place upon the rates. He stated that the number of notifications received during the first three weeks of the year was 1,054, an average weekly of 351. If that average were maintained to the close of the year it would cost a big sum, probably exceeding £1,000. The preventive value of notification in measles was practically nil, and it had commonly been discarded after a short trial in several districts where it had been adopted. Some benefit might be secured in severe complications, bronchitis or pneumonia, by nursing the patients in hospital, but that could only be secured in exceptional times when the fever incidence in the city was low. As no provision had been made in the city hospitals, at epidemic times the number of beds was insufficient to accommodate the fevers for which they are properly intended. In any case he thought that limited amount of benefit to individual cases might equally well be secured by less cumbersome and expensive methods than compulsory general notification, which imposed an expensive obligation of little preventive value on the city at a time when economy was imperative and was enjoined upon communities. So far as he could gather, the Compulsory Measles Notification Order of January, 1916, followed from the military measles outbreak of the spring of 1915 but it was somewhat belated strategy in regard to that happening. He thought the Health Committee might well advise the City Council to protest against this untimely and vexatious expenditure. He also said they ought to get other towns and counties to join with them in their protest.

The Committee agreed to ask the Council to carry out Dr. Davies's suggestion, the opinion being expressed that the notification meant great expense and little benefit.

The Revolt of Youth.

THE manner in which young men of position and assured prospects have thrown all to the four winds, to fling themselves into the war, is of deep significance. It is the expression of the innate desire for vividity, swiftness, and hazard in life, which modern civilisation has half-stifled and thrust into the background of the intellect—but which it has failed to kill outright. Well-nigh choked with the ashes of convention, it nevertheless glows in our boyhood, in minor adventures by flood and field, fanned by the perusal of the penny dreadful; and it leaps into clear flame in the lad who runs away to sea. But in adult life it wanes fast, save when circumstances such as the present bring about a vast intellectual conflagration in an entire nation, to drag the clerk from his stool and put him astride a horse, or the son of a prosperous merchant to drive through the teeth of a flying gale at sea. We are far from denying the clear call of patriotism amongst our young men. But curiosity and a thirst for complete change play a part not appreciated by the superficial observer. It is a matter for congratulation that so much of the primitive child should be alive amongst us all; that so many should prefer a few hours of crowded, and even of terrible life, to an age of dull respectability.

Routine.

MONOTONY of occupation appears to develop two types of humanity, both of whom are of interest from the professional standpoint. The first, and possibly more common variety, thrives upon repetition. His brain and limbs alike act with a mechanical regularity—the despair and envy of the class next to be considered; and he is conspicuous for fertility and longevity. The second group is composed of those who kick against the traces—and, if possible, over them—in their attempt to escape. They are imaginative and neurotic, frequently of fine intellectual temper, but forced by giant circumstance to pass their lives in a state of fret bordering upon neurasthenia; and even when past middle-age, should an opportunity arise, they take the bit between their teeth. Such, it may well be, are the many of the elderly practitioners now upon war service. The point we aim at is, that this class of sufferers constitute a clinical entity, in whom prevention is of supreme importance, to obviate the development of the psychoses; and that a change, not in the mere superficial sense, but even extending to *professional* occupation, is a therapeutic agent, which in certain cases of merely irregular or abnormal temperament may work wonders.

Antiseptics from the Sea.

In the present great war hospital ships have played a part unparalleled in the past in the transport and treatment of the sick and wounded. The question of the disinfection of these ships is thus rendered increasingly important. Were sanitary measures insufficient, a hospital ship carrying, e.g. typhoid patients to England, might be a serious menace. Efforts have been made to devise means of disinfection which should be at once efficient, easily applied, and relatively cheap. According to the *Times*, a large measure of success has been attained by means of an apparatus recently installed in the "Aquitania," under the supervision of Dr. Dakin and at the instance of the Medical Research Committee of the National Insurance Act.

The apparatus consists of an electrolytic cell, a reversing switch capable of carrying 100 amperes, and some ordinary insulated electric cable. The cost is about £50. The cell stands upon a rubber mat to insulate it, and is raised upon a low table to enable its contents to be poured out easily. It is filled with cold sea water, and if a current of 60-75 amperes at 110 volts be then turned on, a solution containing two parts of sodium hypochlorite or available chlorine to 1,000 parts will be obtained in five minutes. The cost of this solution works out at 3d. per 100 gallons.

The solution is also excellent as a sterilizer of drinking water (one part chlorine to one million parts), and as an antiseptic for wounds (used undiluted as produced by the electrolyzer—i.e., two parts hypochlorite of soda to 1,000 parts). Further, in the butcher's department its value was soon evident, and also in the laundry for soaking undyed cotton and linen goods. It was added to the water in the swimming bath of the ship in the proportion of one part in two million parts, with the result that bacteria which had formerly been present in the water to the number of 2,000 per c.c., were reduced to 200 per c.c., a 90 per cent. reduction.

These excellent results have delighted all who have observed them. In the case of the "Aquitania," the economy in largely replacing expensive coal-tar disinfectants, such as carbolic acid, cresol, etc., by electrolytic hypochlorite will approximately

pay for the cost of the cell (£50) in the course of a single trip of three weeks.

The Study of French.

WE welcome the remarks of the French Ambassador at the Mansion House on February 5th, on the occasion of the distribution of the prizes award in the thirty-first annual competition of the National Society of French Masters in England. M. Cambon pointed out that the study of French in England and English in France had done much to develop international sympathy. In the Nineteenth Century there was much rivalry between England and France, accompanied by struggles which were sometimes very sanguinary. But before that century closed the two countries came to recognise that in many essential respects their interests were identical, and gradually they came closer together, though now and then there were temporary misunderstandings. If anything remained to strengthen the bonds of sympathy between the two nations, it was the present war, in which English and French soldiers were fighting side by side for the noblest of causes—the defence of European right and liberty. The entire world admired the self-abnegation and tenacity of those who were fighting for that cause. His Excellency declared that from this war would spring an Anglo-French understanding so solid as to be indestructible and making for humanity, progress, and liberty throughout the world.

The Lord Mayor expressed the belief that the intimacy and affection of the French and the British peoples would soon be so infinitely increased by their having fought together, shoulder to shoulder, in this war, that a knowledge of each other's language must in future be a definite and compulsory part of the curriculum of every college and school in both countries, and must be treated as indispensable in every vocation of life. French must in the years to come not only be the language of diplomacy but, in unison with our own, the language of trade, commerce, and everyday life. He was afraid that the English were not, as a nation, good linguists, but when he looked at the long list of prizes and certificates won by young pupils of schools in this country he felt encouraged to think that, with time, perseverance, and patience, the English might, after all, acquire a better reputation as linguists than they had enjoyed in the past.

THE MEDICAL PRESS AND CIRCULAR has for many years presented to its readers, in English dress, articles by leading members of the profession in France. We wonder if the coming generation of English medical men will be able to read such, with pleasure and profit, in the beautiful language of our gallant allies.

A Surcharge for Over-Prescribing.

A REPORT from the Panel Committee of Aberdeen Insurance Committee concludes, viz.:—"The Panel Committee were of opinion there had been excessive ordering of drugs in the case above mentioned (a doctor on the Aberdeen panel), and they now call upon the Insurance Committee to deal with the matter in terms of sub-section (2) of section 40 of the Insurance Regulations." The result was that the doctor was surcharged £6 5s., being approximately the amount of difference between the cost of prescriptions written during the quarter ending December 31st, 1914, and the amount available in the drug fund on the basis of a fair average as between all the doctors on the panel." This was carried by five votes to four.

Neil Kenyon tells a story in "Doric" of "goin'

into a restaurant, whaur he saw twa chaps at a table. Yin was an Aberdeen man, and the ither had nae money either," and so on. He must have been wrong as to the town. It is evident that Aberdeen, as represented by their Panel Committee, are looking keenly after the cash. Reducing medical effort and work to a fair average: their views on herring-gutting we have no doubt are aseptic and above reproach, but on the treatment of patients ———. Five to four: "Five of them were foolish."

Medical Research and the Carnegie Trust.

THE fourteenth annual report of the Carnegie Trust has just been issued. Even this department of original research in our academic life has been affected by this ghastly war: Six Fellows and nine Scholars are at the front. Some of their places are kept open for their return, which we hope will be soon. This part of the outlay was £7,000 for the year. One hopes that the return, therefore, is commensurate.

At St. Andrews, fourteen beneficiaries, with the help of untrained volunteers, are engaged in the preparation of dulcitol and other chemicals required for medical purposes. This is all right: considering the number of preparations put out for medical use by our enemy, one would say it would be a wise thing now for us to learn this business for ourselves. The report needs more than a casual looking over to size it up. We shall refer to this report later on.

Cutting Down Panel Doctors' Remuneration.

WE notice that the Carnarvonshire Insurance Committee, in regard to payment of the doctors for quarter ended December 31st, 1915, have recommended payment on 72 per cent. of the members on the doctors' panels. They have not yet managed to remove from the panels the names of those enlisted, but by some differential calculus they make out 72 per cent. as being a fair basis of payment. The 28 per cent., consisting of picked, healthy men, are taken off the doctor's lists, leaving him all the weak and unhealthy. These 28 per cent. would have given the doctor no work to speak of, but they still have the weaklings. They have just, then, as much work, and not quite three-fourths of the remuneration. It may be fairly asked: Was the spirit of the Act not to make the healthy patients help pay for attendance on their sick brothers and sisters? That, we take it, is the meaning of the flat rate. Had the authorities plainly said that in this serious time they could not afford the full payment, would it not have been wiser to say so: and the profession would gladly have met them by agreeing on patriotic grounds to do with less. We had better watch lest this is the proverbial thin end of the wedge.

PERSONAL.

COLONEL A. D. SHARP, F.R.C.S., R.A.M.C., C.M.G., of Leeds, has been appointed Assistant Director of Medical Services to the 49th West Riding Division in France.

SIR HUGH OWEN, G.C.B., whose death is announced, took a great interest in questions of public health and poor-law administration. He was an Honorary Fellow of the Royal Institute of Public Health.

DR. WILLOUGHBY MASON WILLOUGHBY, Deputy Medical Officer of the Port of London, and Senior Boarding Medical Officer at Gravesend, has been appointed Medical Officer of Health for the Port, in succession to the late Dr. Herbert Williams, at a commencing salary of £800 per annum.

ORIGINAL PAPERS.

DISEASES IN THEIR RELATION TO OBESITY:

SOME POINTS TO BE CONSIDERED IN REGARD TO ASSURANCE EXAMINATIONS.*

By F. PARKES WEBER, M.D., F.R.C.P., London.

UNDER the following headings only the more ordinary questions are referred to.

I.—DISEASES OF THE CIRCULATORY AND HÆMO-POIETIC SYSTEMS.

It is well known that many obese persons have slight œdema about the ankles when they are up and have not been recently lying down. In most cases this slight œdema is, I believe, not a sign of particularly bad prognostic significance. Occasionally, however, it rapidly increases and becomes associated with shortness of breath on exertion out of proportion to the obesity. It then may constitute an early sign of cardiac failure. Especially is this to be feared in persons who have been formerly addicted to excess of beer (having "beer-hearts") and alcoholic drinks, even when by auscultation of the heart no murmur of valvular disease can be discovered. In such cases signs of so-called "myocarditis" may suddenly arise, accompanied by the characteristic "irregular irregularity" of auricular fibrillation.

In other cases the slight œdema in question may be partly due to varicose veins, and it is only the varicose veins that have to be considered in regard to the assurance.

Occasionally a plethoric type of obesity may to some extent mask the presence of arterio-sclerosis and commencing aneurysm of the aorta. Symptoms such as shortness of breath and thoracic discomfort may at first be wrongly attributed to the obesity, but more exact examination (including the brachial systolic blood-pressure, the estimation of the daily quantity of the urine, the Wassermann reaction and the Röntgen-ray examination of the thorax) will probably quickly reveal the complicating disease.

In very rare cases in pasty obese individuals, pallor and slight œdema may be due to a hæmopoietic disease—namely, pernicious anæmia or an atypical leukæmia.

2.—DISEASES OF THE LUNGS.

Emphysema of the lungs with progressive dilatation of the right side of the heart and other results may be at first masked by obesity. Of great importance is the auscultation of the infra-scapular regions for the more or less permanent crepitation which shows the presence of (what is generally known as) chronic catarrh or chronic œdema of the base of one or both lungs. In this connection one might, I believe, add that recurrent attacks of bronchitis associated with asthma-like breathing are more frequently observed in plethoric fat persons (who have mostly been great eaters) than in others. Pulmonary tuberculosis is, of course, generally associated with under-weight rather than over-weight, but there are exceptions, and old quiescent or obsolete pulmonary tuberculosis may—partly as a result of methods of treatment—occasionally be associated with a plethoric type of corpulence.

3.—DISEASES OF THE LIVER, PANCREAS, AND KIDNEYS.

It is a well-known truism to say that the detection of cholelithiasis or nephrolithiasis may be in various ways rendered more difficult by the presence of obesity. Cholelithiasis is acknowledged to be relatively frequent amongst fat persons, rather more so in women than in men. Obesity may sometimes draw the examiner's attention away, and so, in a sense, "mask" the presence of chronic nephritis (especially contracted granular kidneys), notably so if the urine only intermittently contains albumin, and even then in mere traces. Examination of the centrifuge sediment of the urine for tube-casts may be of some use, but it must be remembered that one or two hyaline or even granular casts may occasionally be found in the urine of practically healthy persons by the help of the centrifugal machine. Estimation of the brachial systolic blood-pressure may likewise help in the diagnosis. Occasionally an ophthalmoscopic examination in such cases may reveal the presence of unsuspected retinal changes (so-called early albuminuric retinitis). In regard to the pancreas, one may remember that the subjects of acute hæmorrhagic pancreatitis are not rarely corpulent individuals, or individuals who have been addicted to alcohol.

4.—METABOLIC DISEASES.

The not uncommon associations of obesity with gout, uric acid gravel, and diabetes mellitus are so well recognised that I need not here enter into any detailed discussion on the subject. Such associations cannot seem surprising, if we remember that obesity itself, whether inherited or acquired, is to some extent a metabolic disease or a metabolic abnormality.

Moreover, over-eating and sedentary habits are certainly not rarely factors in the causation of gout and diabetes mellitus, as they are in the causation of obesity. It is especially the mild form of diabetes mellitus occurring in "middle-aged" and elderly persons (more so in those of Hebrew descent than in others) that is associated with obesity. A "lipogenic" form of diabetes mellitus has even been spoken of.

5.—DISEASES OF THE DUCTLESS GLANDS AND INTERNAL SECRETIONS.

I shall merely mention the chief syndromes associated with excess of fat:—

(a) Dercum's disease, or adiposis dolorosa, a disease which occurs almost, if not quite, exclusively in females of middle age, appears to be due to a disturbance of the internal secretions; it is sometimes connected with disordered action of the thyroid gland.

(b) Diffuse symmetrical lipomatosis of the neck and other regions. This condition is met with almost exclusively in males of middle age, when probably sexual activity is beginning to decline. It is, however, by no means always associated with diminished functional vigour of the sexual organs. It practically only occurs in those who

* Paper read at the Assurance Medical Society, London, January 5th, 1916.

have habitually indulged in malt liquor or other alcoholic drinks.

Sir Jonathan Hutchinson pointed out that in this condition it was especially the fat about the roots of the hair follicles of certain regions that tended to hypertrophy; for instance, that about the roots of the large pubic hairs in man. He compared it to "nuchal lipoma," developing about the mane in asses. Diffuse lipomatosis of the neck has been known in Germany as Madelung's "Fetthals," because Professor O. W. Madelung wrote about it in "Langenbeck's Archiv." in 1888. In France a theory was started that the characteristic forms of symmetrical lipomatosis were due to a kind of semi-inflammatory development of fat, spreading from the various regional groups of the (in some way diseased) superficial lymphatic glands. Hence the term "adeno-lipomatosis" was applied to the condition. (a) (Compare the paper by Launois and Bensaude, "L'Adéno-lipomatose symétrique à prédominance cervicale," in *Presse Médicale*, Paris, for June 1st, 1898, p. 296.) In England an excellent account of symmetrical lipomatosis was published by Marrant Baker and Bowlby in the "Medico-Chirurgical Transactions" in 1886 (London, vol. 69, p. 41), but I believe the condition had been already described by Sir Benjamin Brodie. In these cases hepatic cirrhosis and ascites sometimes supervene.

(c) Fröhlich's pituitary "syndrome of adiposity with insufficiency of the sexual organs" ("dystrophia adiposo-genitalis," or "dystrophia genito-adiposa") is thought to be connected with hypopituitarism, that is to say, with deficient functioning of the anterior (glandular) portion of the hypophysis cerebri.

Various atypical cases of adiposity, supposed to be connected with pituitary disease, have been described, some of them as examples of a "pluri-glandular syndrome."

(d) Most cases of "eunuchoid" obesity in men whose sexual organs were never well developed, or have undergone atrophic changes, are probably allied to the preceding group.

But internal secretions from the testes and prostate seem to have some influence antagonistic to the accumulation of fat, and adiposity in males may doubtless be favoured by castration or by diseases of the testes and prostate gland. In women the menopause is apparently often followed by a tendency to obesity, and so is a premature menopause resulting from oophorectomy and operations on the pelvic organs or from ovarian disease. It must not be forgotten, however, that disorders of the pelvic viscera in females frequently lead to a sedentary mode of life, and thus indirectly favour the development of obesity. Moreover, one of the reasons why obesity is altogether more common in women than in men is probably the greater frequency of sedentary habits in women.

(e) A condition which may be legitimately described as "precocious obesity" has been occasionally observed in children in association with new growths of the type of malignant "hypernephroma." The children in question exhibit a coarse florid plethoric obesity, giving rise to broad crimson or purple-coloured "striae atrophicæ" of the skin of the buttocks, thighs, etc. They look much too old for their real age, and tend to precocious development of the sexual organs; a little girl thus affected might look like a coarse farm woman, 30 to 40 years of age, who had been much exposed to the weather and had been very liberally fed. This

(a) I believe that this term owes its origin to an error or to a chance association, and that in most cases the lymphatic glands of the neighbourhood are not in the least diseased.—F. P. W.

precocious obesity occurs more in girls than in boys; in boys the hypernephromatous disease sometimes gives rise to muscular excess without obesity, the exaggerated development of the skeletal muscles giving the boy the appearance of an "infant Hercules" (in antique Greek and Roman art).

(f) A condition of "lymphatism" associated with excess of subcutaneous fat may perhaps likewise be mentioned under this heading.

Seeing how much the prognosis in obesity (often even when associated with other diseases and morbid conditions) is modified by rational treatment and the fat person's intelligent control over himself, I may be permitted to add a few words of old oft-repeated advice. Half the cases of ordinary obesity might have been kept within bounds, or entirely got rid of, by a timely recognition of two old mottoes: "Principiis obsta" (*Ovid*, "Remedia Amoris," 91); and "Immodicis brevis est ætas et rara senectus" (*Martial*, *Sat.* VI., 29, 7)—in other words, by early practising strict moderation in eating, etc. The excess of the intake (fuel) over the output (work, etc.), may lead first to obesity and then, by a process of choking of the human furnace and chimneys and clogging of the machinery as a result of imperfect combustion, to metabolic diseases, etc. W. Ebstein has divided ordinary cases of obesity into three stages, namely, the enviable stage, the comic stage, and the pitiable stage. It is in the third stage—the pitiable or "helpless" stage—that the wretched person loses bodily strength and activity, cannot take exercise, and has often no longer the will-power to resist his complaint. It is in the first state, that is, the stage of plumpness or *embonpoint*, the stage admired by many, that strict moderation in eating, etc., ought to become a habit of life. Several years ago Sir William Osler drew attention to the advantages occasionally derived from a trace of albumin being discovered (at life assurance examinations, etc.) in the urine of men over fifty years of age, (a) and quite recently he (b) has alluded again to an instance in which a distinguished man, when 60 years of age, was found to have a trace of albumin and a few tube casts in the urine. Sir Andrew Clark, who was inclined to take a grave view of the renal condition, gave good advice, and the patient, who was himself a medical man, ever afterwards lived a careful life, and reached the patriarchal age of 94. I am sure that if the relatively early stages of obesity were more generally regarded in a serious light by life assurance companies, or rather, by their medical advisers, and if slight extra ratings were more generally insisted on and if that became universally known to the lay public, many more "candidates" for the higher grades of obesity would be inclined to alter their manner of living in time to avoid arriving at the helpless stage. Of course, it is not directly from their obesity that most fat persons die but from the complications of obesity or the diseases associated with it. The treatment of these conditions is naturally beyond the scope of the present discussion.

In regard to the relative frequency with which different diseases are found associated with obesity, it is, I think, worth while appending the following statistical data, beginning with the most recent. But I have hardly made use of them in formulating the first part of my paper.

(a) Osler, "On the Advantages of a Trace of Albumin and a Few Tube Casts in the Urine of Certain Men over Fifty Years of Age," *New York Medical Journal*, November 23rd, 1901, Vol. 74, p. 949.

(b) Obituary Notice on Sir Charles Tupper, *Lancet*, 1915, Vol. ii., p. 1050.

TABLE I.—From I. Romanelli's paper on Obesity and Life Assurance in *Il Policlínico* (Sezione pratica), Rome, August 8th, 1915, Anno XXII., p. 1061.

During the years 1913 and 1914 an Italian Assurance company (Istituto Nazionale delle Assicurazioni) rejected 308 obese candidates. In 36.38 per cent. the obesity was apparently present without complications; in 21.75 per cent. it was associated with glycosuria; in 10.38 per cent. it was associated with nephritis; in 7.18 per cent. it was associated with albuminuria; in 5.84 per cent. it was associated with heart trouble; in 5.19 per cent. it was associated with arteriosclerosis; in the remaining cases there were various complications, such as syphilis, alcoholism, bronchial catarrh, etc.

FROM TABLE SHOWING THE CAUSES OF DEATH IN 1,114 ASSURED LIVES.

Cause of Death.	Underweight (per-centage of the total number of under-weight deaths).	Normal weight (per-centage of the total number of normal weight deaths).	Overweight (per-centage of the total number of over-weight deaths).	Total percentage of the total number of deaths).
Pulmonary tuberculosis	21.3 (22.3)	12.5 (75.0)	0.9 (2.7)	10.0
Acute pneumonia	3.4 (5.2)	8.2 (71.4)	5.5 (23.4)	6.9
Cancer	6.9 (11.3)	5.5 (52.1)	7.7 (36.6)	6.3
Cerebral Apoplexy	3.4 (6.3)	3.0 (31.2)	12.3 (62.5)	5.8
Bright's disease and nephritis	2.6 (6.0)	3.1 (42.0)	8.0 (52.0)	4.5
Hepatic cirrhosis and alcoholism ..	0.9 (2.3)	2.7 (40.9)	7.7 (56.8)	3.9
Cardiac disease of uncertain nature ..	1.7 (4.8)	3.0 (47.6)	6.1 (47.6)	3.8
Typhoid fever	2.6 (8.3)	3.6 (66.7)	2.8 (25.0)	3.2
Influenza	1.7 (5.5)	3.7 (69.5)	2.8 (25.0)	3.2

PHYSICALLY DEFECTIVE CHILDREN AND THE PROBLEM OF THEIR EDUCATION.*

By W. A. WINTER, M.D.,

Physician to Dr. Stevens' Hospital, Dublin; President of the Section of State Medicine in the Royal Academy of Medicine in Ireland.

WHEN deciding to address you on the problem of the education of the physically defective child I was fully aware of the fact that the present is not the most suitable time to expect public bodies or the philanthropic public to embark on schemes entailing increased expenditure, but I also knew that in order to induce people to take up a question of this sort it is first of all necessary to educate public opinion, for it is usually the general public who start these questions while Government departments absorb them at a much later date.

To convince you that it is necessary to educate Irish public opinion in this matter I need only mention that, as far as I have been able to ascertain, there is no day school for physically defective children in Ireland, though the Orthopædic Hospital and the South Dublin Union Infirmary have schools for their inmates: the former is recognised by the National Board of Education, but the school in the South Dublin Union is under the sole control of that Union. In addition to these schools, I understand that some instruction is given by voluntary teachers at the Children's Hospital in Harcourt Street, Dublin, and I have also reason to believe that in Belfast the subject is under consideration for tuberculous children.

I do not propose in the limits of this address to deal with the cases of the mentally defective or the blind children; they are to a great extent already looked after by public bodies or private philanthropy, nor do I propose to address you on subjects or methods of instruction.

It must have come under the personal observation of most of you that the child who suffers from physical disability is not necessarily also endowed with a dull brain; indeed, I think the reverse is not

* A Presidential Address delivered before the Section of State Medicine in the Royal Academy of Medicine in Ireland, on Friday, January 7th, 1916.

infrequently the case, as we sometimes find that the delicate child is often mentally and in technical matters more than usually receptive of instruction. One has but to recall the wonderful work that has been done by tuberculous people in order to admit to ourselves that, in spite of their ailing bodies, their minds have been able to acquire knowledge, while their imagination and skill with their hands clearly demonstrate to us that in this class, at least, of physical defectives the mind is not infrequently hyperacute.

Left without education, the outlook for delicate children is very dark, for it is probable that, being unable to earn their livelihood, they will ultimately drift into the wards of the workhouse or will go to swell the numbers of the unemployable or criminal classes; in either case they become a charge on the community, and it is because I think that this class—more particularly the cripple—needs education more than most children that I bring their case before you this evening, for they are debarred by their infirmity from competing on even terms with their more healthy fellows, and are compelled to offer superior knowledge or extra technical skill in order to compete on level terms with them, and if they are not thus endowed they can only hope to be employable in a limited field, where in some sedentary occupation they may obtain a living wage by possessing a good general intelligence or some skill with their hands.

Dr. Rayner has defined the physically defective child as one "who suffers from some defect or disease, other than a mental one, which seriously

interferes with ordinary school life and which is likely to operate against the efficiency of the child viewed as a prospective citizen." This is a wide definition, and I think it takes in all the cases that it is necessary for us to consider. In Ireland, owing to the fact that we have no medical inspection of school children, we have not any means of ascertaining what is the number of these children. Had we that inspection we would not only know the number, but would, perhaps, be in a position to estimate the relative numbers of these children in the towns and in the country, and also what influence was played by heredity and what by environment. The former is, I think, comparatively unimportant, and may, in many cases, be remedied by due care and precaution in the latter by attending to the food and lodging, and the education and physical development of the child.

From the medical standpoint it is, I think, a hopeful sign that professional educationalists are now showing a tendency to think less of subjects and more of the individual child, with more regard to its bodily welfare, its individual capacity, and its natural tendencies. The practical outcome of this is seen in the number of special schools that have come into existence in England in the last fifteen or twenty years: in the year 1911 there were 34 of these special day schools in England, 24 of which were in the county of London, while there were also three residential schools; this number has now been increased. I regret that I am unable to give you the present figures, but a side-light is thrown on the question by the fact that the Educa-

A, B and C in above table refer to the same classes as in the previous table.

tion Committee of the London County Council publish a book of regulations for special schools, which contains 190 pages.

I may, perhaps, be allowed again to refer to the question of environment and its relation to the health of children, for there can be no doubt that much chronic invalidism in children is directly traceable to this cause. Dr. Arkle of Liverpool carried out an investigation of 2,000 children attending various schools in that city. He divided the cases into four classes, and his tables go to prove that the better the social status of the families, the better was the average height and weight of the children; and he also gave a table which showed that, as a rule, the general nutrition of the children was proportionate to the wages earned by the parents.

The above tables are full of interest, and you will be especially interested, I think, in class C, showing as they do a lower average height and weight, and also a poorer state of general nutrition; and, I think, it is reasonable to assume that the children of this class will furnish more than their correct proportion of invalid children; some, indeed, will only need to attend schools because the general conditions of home life are so bad; but this class is also, I think, likely to supply more of the cases of rickets and tuberculosis in its various forms than classes A and B.

We can get some idea of the number of cases likely to need special schools, by consulting figures that have been published in England and Scotland, where it has been estimated that about 5 per cent. of the children are suffering from defective hearing, sufficient to draw the teachers' attention to it, while an investigation of the hearts of 600 school children in Edinburgh showed that 15 of them suffered from valvular disease, and when you add the cases of tuberculosis and rickets the number of invalid children will be very greatly swelled. What I have said will, I think, suffice to prove to you that there are many children who cannot attend an ordinary school, or, if they do so, they cannot attend regularly, or with a fair prospect of deriving average benefit from such attendance.

We can, perhaps, make a rough estimate of the number of delicate children likely to be found in Dublin by consulting the figures published by the Education Committee of the London County Council for the year 1913-14, which states that the total cost of special schools in the county of London for that year was £70,694, at an average cost of £23 per child, which would make it appear that the number of children attending special day schools in London was about 3,070, and assuming the proportion of these children to the total population is the same in London and in Dublin, it would appear that there are about 200 children suitable for attendance at special schools in this city.

How does London deal with these children? I mentioned earlier in my address that in 1911 there were 24 special day schools under the County Council. These schools are scattered all over London, and are grouped in such a way that it is designed that no child shall be compelled to travel more than two miles in order to attend school; children who can travel by 'bus or train are supplied with tickets, which are available during the school term, and any children who are unable to travel in public conveyances are collected by special 'bus or ambulance. Each of these vehicles is in charge of a nurse or attendant, who is responsible for the collection of the children from their homes or a stated centre, and for their delivery to their parents at the conclusion of the school day; in addition to this special guides may be employed. Ambulances have accommodation for two stretcher cases, and for 10 or 20 children, according as the vehicle is a one or two-horse one. The nurse is in attendance at the school all day, and is, as a rule, I believe, consulted by the head mistress as to whether an apparently ailing child is fit to have instruction on any particular day, and even if the child is unfit to benefit by instruction its presence at school costs as an attendance for the purpose of grants. Technical instruction is given in all special day schools in London. No mentally defective child is admitted to these schools for physically defective children.

Mid-day meals are served at all special schools, and such meals are free in all cases that are deemed to be necessitous. It is one of the duties of the nurse to superintend the preparation of this meal, and to be present while the children are eating it;

the nurse is further of great use in keeping the school medical officer in touch with the parents of the pupils, and their home surroundings are noted, and, if possible, improved. While at school suitable couches, etc., are supplied for all cases that need them, and the medical officer is, of course, responsible for saying how much instruction, if any, a particular child is to receive, and it is his duty to attend at the school at least once every week, and oftener if required.

Owing to the necessarily somewhat irregular attendance of the children at these special schools, the regulations of the School Board permit of a somewhat larger number of pupils being on the school roll than is allowed for similar accommodation at an ordinary day school, the figure in all special schools being 10 per cent. in excess of the apparent accommodation of the buildings.

In Ireland, as I have stated before, we have no special day schools, but it is probable that the Commissioners of National Education would frame rules to suit such schools, and one of their fundamental rules states that in order that a school should be recognised for the purpose of grants, it must have an average attendance of at least 20 pupils between the ages of 3 and 16 years; but rule 179 would seem to show that they have a discretionary power, for it says:—"In certain cases—namely, where means of religious instruction are not obtainable by children of a particular denomination within reasonable distance of their homes—the Commissioners are prepared to make modified grants to schools in which the average attendance is less than 20." It would thus appear that the Commissioners have discretionary powers to recognise small schools on the grounds of religious instruction, and they would, I think, probably be prepared to recognise small schools especially designed to promote the education of the physically unfit.

From a letter which I received from the Commissioners of National Education in Ireland last November, it would appear that their attitude is favourable to the question of special schools, for, in their letter they state that they had given favourable consideration to preliminary enquiries with reference to the proposal to start an open-air school in Dublin and also in Belfast. The former scheme has not been proceeded with, but the latter is still under consideration, and they further point out with reference to the school at the Orthopædic Hospital that each child receives instruction for only one hour daily, instead of four hours as in an ordinary national school, and that the subjects taught are modified to suit the case of these special pupils. Yet, I understand that the grant given to this school is sufficient to cover all expenses, and that it is carried on without being in any way a drain on the funds of the charity. There are usually about 50 pupils on the roll of this school.

I have previously referred to the fact that in 1911 there were three residential schools in England for physically defective children, and I have read with great interest an account published by Dr. Telford, giving details of the work and management of the school at Swinton House, Manchester, which was started in 1905 by the Education Committee of that city, and had at that time accommodation for 60 children. This number of beds was found to be quite inadequate, as, at the time Dr. Telford wrote his paper in 1910, there were 120 suitable cases on the waiting list of this school hospital. The Education Committee had, however, by this time become so thoroughly satisfied that the scheme had justified its existence, that they had taken the lease of an adjoining house and grounds, and were preparing it to receive another

60 children, so that Manchester now possesses a residential school capable of accommodating 120 invalid children.

In a general way it may be stated that experience has proved that the majority of the cases suitable for admission to this class of residential school are cripples, and Dr. Telford divides them into two classes—(a) stationary; (b) progressive. In the former class he puts the children who are suffering from a disability, the cause of which has ceased to be active. Under this heading come cases of rickets, injuries at childbirth, congenital malformations, and infantile paralysis; while the progressive class is almost entirely made up of cases of surgical tuberculosis, and inasmuch as the object of these schools is twofold—in the first place to educate the child, and in the second to endeavour to cure or remedy the effects of the disease or disability—you will, I think, agree that it is necessary that the greatest care should be taken in the selection of cases for admission, and how useless it would be to admit children when there is little or no hope of being able to cure the disease or remedy defects already present; and in practice it has been found that the rule which is enforced in most sanatoria for pulmonary tuberculosis, only to admit early cases, applies with equal force to the cases of surgical tuberculosis admitted to these schools, because failure to observe this fundamental rule will lead to disappointment, and the natural question will follow: Is the expenditure justified?

When selecting cases for admission it must always be borne in mind that these children are being admitted to a school, and the first necessity in a candidate for admission is that the mental and bodily condition of the child should be such as will enable it to receive regular instruction, and a vast majority of such suitable cases are usually recruited from these classes:—

- 1.—Rickets.
- 2.—Infantile paralysis.
- 3.—Early tuberculosis.

The above cases usually do well, but with reference to the third of these classes it has been found by experience that cases which have gone on to the formation of abscess usually prove unsuitable.

With regard to the general management of the school, it is run somewhat on hospital lines. Great care is taken as to the diet of the children, and it is also considered to be of the utmost importance that as much of the day as possible is spent in the open air, and when weather conditions are at all favourable all instruction is given out of doors. There is an ample playground attached to the school, and it has been found to be greatly to the advantage of the school that it possesses large gardens which are not only able to supply fruit and vegetables to the school, but are also a source of profit, and are further of use for the training and amusement of the pupils. The school also possesses its own dairy, which keeps the children supplied with plenty of good milk, and is also a source of profit to the institution.

No operations are performed in the school, as it has been deemed to be more economical and better for the children that they should be removed to hospital when active surgery is required.

There still remain two important matters for our consideration—the results of the school and its cost.

During the first five years of its existence, 98 cases were discharged from the school. Of this number 37 went to an ordinary day school, and 12 to work, while 19 were removed by their parents.

The 98 cases were made up as follows:—

Tuberculous disease of spine	39
" " hip	21
" " knee	8
" " ankle	1
Rickets	18
Paralysis	8
Congenital dislocation of the hip	1
Amputation of leg for injury	1
Ununited fracture of leg	1
	98

These cases were discharged as indicated below:—

1.—Discharged to an ordinary day school ...	37
2.—" " to work	12
3.—" " as unfit for education ...	24
4.—" " on reaching the age limit ...	3
5.—Died	3
6.—Removed by parents	19
	98

The cases discharged to an ordinary day school were:—

Tuberculous disease of spine	8
" " hip	9
" " knee	1
Rickets	14
Paralysis	3
Amputation of leg for injury	1
Ununited fracture of leg	1
	37

While the cases discharged to work were:—

1.—Tuberculous disease of spine	3
2.—" " " hip	4
3.—" " " knee	2
4.—Rickets	2
5.—Paralysis	1
	12

Of the 24 cases discharged as unfit for education, 21 were cases of tuberculosis, and 3 were mentally unfit.

With regard to the cost of education, etc., at Swinton House, it would appear that the average cost is about £50 per head per annum. From the first it was established as a principle that all parents who were in any way able to do so were expected to contribute towards the cost of the maintenance of their child; other sources of income were contributions from outside authorities, Government grants, sale of cattle, plants and farm produce; receipts from all these sources amounted to about two-fifths of the total cost of the school, leaving the remaining three-fifths to be made up out of the rates, or, in other words, the cost to the local ratepayers was about £30 per head per child. It may here be pointed out that while Parliament has sanctioned the erection and maintenance of these residential schools, it had so far—1910—given them no special consideration in the matter of grants; this ought not to be, and I think you will agree with me that considering the amount of work done for the State by this school in the year 1909-10, the grant of £4 per head was, to say the least of it, inadequate.

You will naturally ask—Is the expenditure of £30 per head for each pupil a charge on the local rates that is justified by results? In this connection I must, first of all, remind you that Swinton House is not only a school, but also a hospital, and in this dual capacity the expenditure is not, I think, excessive, especially when we consider the results; for you will remember that during the first five years of its existence 98 cases were discharged, and of these 50 per cent. were either discharged to an

ordinary school or to work, while 19 were removed by their parents, and some of these cases were so improved that Dr. Telford says he has no doubt that they eventually got quite well. Still, I think that, even omitting these doubtful cases, the experiment of the Manchester Education Committee has been justified by its results, and that they are justified in increasing their accommodation.

How far later legislation has made further Government grants available for these schools I am not quite certain, for, under the medical grant regulations the Board of Education may now give a sum of £8 a year, which is paid direct to the school, and further, there is the "Hobhouse grant" of half the amount paid by the local authority sending the child to the school. If these grants—which I think are only available for tuberculous cases—are available for schools like Swinton House, it would materially reduce their cost to the local ratepayers, as for the year under consideration the number of cases that could be classed as tuberculous was 39, and the increased grants would considerably reduce the cost of keeping up the school from the point of view of a local authority.

The question of the grant-in-aid for the education and treatment of tuberculous children naturally makes us inquire what is being done for children suffering from pulmonary tuberculosis. In England there appears to be a growing tendency to provide special accommodation for them, but in Scotland and Ireland it does not, as far as I am aware, exist, though I think it is probable that some effort will be made to make such provision, because the experience of sanatoria all over the world seems to be strongly in favour of children being treated apart from adults. It is the usual custom in these special sanatoria for children suffering from pulmonary tuberculosis to have a school attached to the institution. This is particularly necessary, because practical experience has proved that many of the cases sent for treatment could, with more justice, be classed as suspects than as definitely tuberculous. They are thus able to receive education, and it is necessary that they should receive it.

The question of open-air teaching is a difficult one in this climate, but it can, and is, being carried out to some extent in our own city. The schools at Rathmines, Whitefriars Street, and Ringsend give open-air instruction in favourable weather; while other schools are considering the question, and show a tendency to increase the size of their windows and make them open more thoroughly.

The open-air school can be maintained in cold climates, as is shown by the fact that in America there were only three of these schools in 1908, and there were 63 in 1913. But we must remember that, although the temperature there is lower, the air is much drier than in these islands.

Sir George Newman in his last report referred to these open-air schools, and laid it down as a principle that they were not merely a school in the open air, but rather aimed to teach a way of life, and also a system of education and medical treatment. According to him the chief characteristics were:—

- (1) Fresh air and sunlight.
- (2) A proper and sufficient diet.
- (3) Rest.
- (4) A hygienic way of life.
- (5) Individual attention.
- (6) Medical treatment
- (7) Special educational methods.

The first and second of these principles it is not necessary to dwell on before an audience of medical men, but the third is somewhat in danger of being

overlooked; and from what I have read in the accounts of various open-air schools in England and abroad it is a fundamental law in their constitutions. What John Hilton wrote in 1860 is equally true to-day, though its precept is not in keeping with the spirit of our times. "Rest," he says, "is the necessary antecedent to the healthy accomplishment of both repair and growth," and you must have frequently had cause to observe that many children, particularly those of the poorer classes, do not appear to get a sufficient number of hours in bed, and you will, I feel confident, agree that rest in the recumbent position for from 1½ to 2 hours daily, during which time they are encouraged to sleep, must be of benefit to delicate children.

In his report, mentioned before, Sir George Newman estimates that about 10 per cent. of the children in London are in need of treatment in open-air schools. The most suitable cases are the anæmic and debilitated children who appear, he states, to be almost universally benefited by the treatment, though, of course, it has its limitations and its negations, for when we consider the uncertainty of our climate and the ill-clothed condition of many poor children, it will at once become apparent that it will be necessary to provide sufficient shelter for unfavourable weather, and for keeping the children warm; and indeed it appears to me that it is looking for trouble, and likely to bring open-air schools into popular disfavour if we attempt to educate a cold and wet child in the open air.

You will probably like to know what is the opinion of professional educationists on open-air schools. I have read the opinions of a good many teachers or ex-teachers on this point, and all appear to be of opinion that—in suitable surroundings—the open-air class is more attentive, better in discipline, more receptive of instruction, more interested in its work, and that they and their teachers leave the school much less fatigued than after an indoor day, while from the standpoint of health they are impressed by the improved general condition of the children and their unusual freedom from colds. The opinion of Mr. Henry Bryett, late head teacher of a school in West Ham, is worth quoting. He says:—"Educationists who are interested in experimental methods will be glad to know that the quality and amount of work done outside is better than that done by the same class working in the rooms, and that mental weariness, so noticeable at the end of a school day, is lacking in the classes that have done its school tasks in the play-grounds. The contrast between children of the open-air section and the same children from a room, at the close of the day, is most marked."

Although it does not really come under the title of this address, it will, doubtless, come into your minds that if this line of education is beneficial to delicate children, it would also benefit the healthy scholars, and experience has proved that this is so, and outdoor instruction applied to healthy children has proved such a success that some of the educational authorities in England have gone a step further and have initiated trips to the country lasting for a week or a fortnight. These trips are now officially recognised by the Board of Education, and are allowed to take place during school term, and the instruction given at these country outings is recognised for the purposes of grants. The cost of these educational trips has, in some cases, been as low as 6s. per week per child.

The thoroughness with which open-air instruction is carried out varies greatly in different places, and perhaps the most extreme régime is carried out at Laysin, under the direction of Dr. Rollier. It is designed more especially for cases of surgical and medical tuberculosis. The school is situated on the

mountains; here you may see teachers and pupils at lessons and at play clad in the scantiest of bathing costumes, a costume that is adhered to even when the snow is deep on the ground. The underlying idea of the treatment is insolation, and certainly the costumes adopted offer a very slight mechanical obstruction to the therapeutic measures.

In England and on the Continent, and in America, it is usual to provide ample covering and shelter for the pupils; this point is particularly attended to when the children are at rest either in the open or on a verandah, and if they work in the open it is usual to see that they are efficiently clothed, and also some arrangement is usually made for keeping their feet from coming in contact with the ground, while the duration of sitting still lessons is curtailed, and is often followed by some instruction or play involving physical exertion. In this connection I note in the time-table of one American school that the first 15 minutes of the school time-table is entered as "getting warm."

I have endeavoured to bring to your notice this evening some of the means that are being employed to promote the education of the physically defective child. I do not lay claim to any originality in the paper, and in the writing of it I am solely actuated by a desire to draw your attention to the comparative neglect of these children in Ireland. Viewed as potential citizens under present circumstances, they are likely to be brought up incapable of earning their livelihood. Many of my hearers are attached to the staffs of our Dublin Hospitals; in the children's wards will be found cases lying for lengthened periods. They are, in most cases, learning nothing even if well enough to receive instruction. The number is usually too small for a school, but it is not impossible that some private effort might be made to render these children less unfit mentally to earn their future livelihood. It appears to me that the problem of educating these children is especially important at present, for when the war is over money and men will be of the utmost importance in these countries, and the question of the well-being of the children will come more before the public and the State. I think it will be our duty as medical men to do all that we can to promote their welfare, and to endeavour to influence the public to take an interest in the problem of the delicate child; we must try to keep them alive, and it is cheaper for the State to educate them than to support them in later life out of the rates. It is, therefore, our duty, and also our interest, to endeavour by means of attention to their mental, moral, physical and technical education to make them into useful, if not fully effective, citizens, who will, in some cases at least, be capable of being made self-supporting, instead of, as is too often the case at present, becoming human derelicts living entirely on charity or the public rates.

SUBNORMAL TEMPERATURE IN TUBERCULOSIS.*

By ARTHUR K. STONE, M.D.,

Boston.

THE occurrence of persistent subnormal temperatures in tuberculosis cases has attracted my attention for a long time, and I have been in the habit of calling the attention of my students to the fact that at a certain period of the disease, usually succeeding the active febrile stage, there is often a period when the temperature curve shows marked excursions in the subnormal, the temperature at no time rising above 98.6° F., and rarely fully reaching

that point. The patients during this period of subnormal temperature are usually improving and making distinct gains, but it takes very little to give them exacerbations of real febrile temperature, lasting for a few hours to a few days. This period of subnormal temperature may last for weeks, the curve becoming less and less irregular if the improvement continues, and finally becoming a continuous straight line at 98.6° F. Until this latter condition is found, I do not allow my patients much more latitude in their movements than I do while in an active febrile stage. Incidentally, I do not like the term "subfebrile," often used to denote a range of temperature from normal, or 99° F., to 100° F. In talking to patients, we may feel justified in stating that such ranges are of little importance. If, however, they persist, I believe that they are of the greatest importance, and that it is our duty to find a cause. It may be the part of good practice in a very few cases to ignore such a temperature and to smash the thermometer, and say that no attention is to be paid to slight changes in the body temperature; but I feel that we must be very, very sure that such a procedure is correct, and that we are not deceiving ourselves, as well as our patients, when we say that subfebrile temperatures are of no consequence. To my mind, when there is a constant variation of the temperature from the normal, it means that there is a pathological process going on in the body which we may not be able to account for; that, however, is our ignorance, and not because the patient is in a truly normal condition.

The persistent subnormal temperature has become to me a part of the regular course of a case of tuberculosis that is on the whole progressing favourably. It does not have prognostic value, as a patient may from this stage again become febrile, although on the whole the tendency is, under favourable conditions, for the temperature curve to become a practically straight line.

Mild tuberculosis infections frequently show a rapid change from a febrile condition to this subnormal condition. This is graphically exemplified in some charts in a short paper recently (1913) published by Rundle, of England, demonstrating the beneficial effects of tuberculin when the temperature becomes subnormal and remains so, although he calls it "practically normal."

One finds the same condition occurring in tuberculous pleurisy. The fluid is withdrawn or spontaneously disappears; the fever disappears, and is replaced by this subnormal condition. All told, I have come to consider this persistent subnormal temperature so constant an accompaniment of tuberculosis becoming quiescent, that it may be considered of diagnostic importance.

During the past year it has become impressed upon me that these facts which I knew so well were not generally appreciated. I was asked by house officers to explain subnormal temperatures, and received looks of incredulity when I replied that it meant tuberculosis. They rejoined that they thought from their reading that sick cases of tuberculosis always had fever.

Later, a patient whom I saw in consultation gave me the following history:—She was an overworked mother. She had had a "cold" in the spring, which had persisted. For a month or two she had persistent fever, often over 100° F. Her physician had not been able to demonstrate bacilli or any definite lesion of the lung. After a time the cough had become less, and she had a persistent subnormal temperature, and all the time felt so tired and worn out that she could keep about with difficulty. She had been told that, because of the subnormal temperature, she could

* Transactions of the American Climatological Society.

not have tuberculosis. Not having tuberculosis she had not stopped and rested, neither had the physician insisted upon rest, as he would have had he made this diagnosis. There was little in the lungs on which to render a diagnosis, but the picture, to my mind, was typical of a mild infection overcome by fair climatic surroundings, with the consequent depressed physical condition and the manifestation of subnormal temperature which was persisting, and calling loudly for further rest to enable the cure to become complete. The persistence of the temperature in the subnormal, to my mind, was the typical thing to be expected, and not the condition to make the case perplexing.

The books on tuberculosis, I find, practically do not mention persistent subnormal temperature as a common symptom to be found in the course of the disease. Pottenger, of course, has made note of the fact. He says (p. 54), "There are types of temperature which persistently remain below normal, 97° to 99° F. [He gives temperature charts to illustrate.] Such cases seem to do well, and, in my experience, I have been unable to account for the condition." Also, in his paper on the "Study of Fever in Tuberculosis," read at Los Angeles in 1911, he states: "The continuously subnormal temperature we associate with both chronic fibroid tuberculosis and chronic tuberculosis of the ulcerative type during the state of quiescence." (Charts.)

These were all the references to subnormal temperature that I had found until Hawes's book, "Early Pulmonary Tuberculosis," appeared, in which he calls attention to the importance of a subnormal temperature combined with high pulse-rate as very suggestive of a probable diagnosis of tuberculosis. I entirely agree with him that a rapid pulse and the low temperature usually go hand in hand, although a number of my charts show a much lower range of pulse-rate than he suggests as the usual.

Practically all writers have noted that persons with tuberculosis may have a normal temperature while disclosing signs of activity on physical examination. Also, all have noted the fact that morning subnormal temperatures are common, but they assert that by afternoon the temperature rises to 100° F. or more. In Kleb's handbook Minor points to the diagnostic importance of the persistence of subnormal temperature in early cases. Incidentally he has some charts where there are persistent subnormal temperatures, or broken only by the fact that many persons unfamiliar with the details of the care of tuberculosis patients are frequently alarmed at low subnormal morning temperatures, citing the case of a surgeon who felt he had saved his patient from desperate collapse because he had found a morning temperature of 96° F.

With all of these observations I fully agree, and, further, I wish to emphasize that the continuance of a subnormal temperature, lasting over weeks, is not at all an infrequent condition in the course of improvement in a patient with tuberculosis.

To make sure of the number of cases that occur, I have been over the records of the House of the Good Samaritan since 1907. During that time we have had 378 cases of tuberculosis, many of them being brought there at the very end of life. Many had had steadily progressing disease, and only a few were in a really early stage, or, in spite of advanced progress on entrance, became arrested. Of the 378 cases treated, I found that fifty-eight of them, for two to four weeks at a time, and some several months, ran a subnormal temperature.

At the day camp at the House of the Good Samaritan, the patients were for the most part

early cases; a large proportion, however, having well-marked signs and bacilli of tuberculosis present. I looked over the first hundred cases treated, and found that forty-one had periods of subnormal temperature, several of them showing the condition for several months at a time, others for periods of a couple of weeks, broken by periods of fever for a few days to a week, and again returning to a subnormal range.

The question may be asked: What is a normal temperature, and what do we mean by a fever and by subnormal temperature? Is there not a variation in temperature in health that is greater than what we are accustomed to consider as the normal variation? Personally, I do not believe so. The physiologists tell us that there is some variation in temperature in the healthy person. This diurnal swing is usually considered to be confined to about 1° C., being lowest during the early morning hours and highest in the late afternoon. The temperature is also stated to be affected by food, and, at times, by exercise.

In order to be sure that the temperatures of patients were persistently subnormal when so appearing on a daily morning and evening chart, I have from time to time had a number of cases tested by having the temperatures verified, by having them taken at three-hourly intervals, and later at two-hourly intervals, to conform to the strictest requirements which I have found set forth as desirable.

Many times, when I have seen subnormal temperatures registered, I have requested the head nurse to look into the methods of the nurses recording the temperatures, and have been assured that the observations recorded were correct. The subnormal temperatures were found equally in the heat of summer and the cold of winter. On the whole, I am quite sure that so far as the observations go, the maximum subnormal are correct; that the minimum may be occasionally lower than recorded I am not so sure.

Blake's observations on Marathon runners made it seem improbable that the irregularities in temperature which are reported could have been observed in truly normal persons. Those Marathon runners showed at the end of their great exercise a rectal temperature of from normal to 99.2° F., and rarely more. My speculation is that many of the so-called normal individuals who have shown marked irregularities of temperature would, on careful examination, have been found to have had tuberculous lesions or some other pathological process which would have accounted for their unstable heat regulation.

However, subsequent investigations shall decide in such cases, for the practical clinical man, when there is no special condition leading to a persistent rise in temperature or to a persistent subnormal temperature. Either of these conditions observed over a long period of time makes the diagnosis of tuberculosis probable.

It has surprised me, since I have been interested in this matter, how few of the conditions where there is general depression were accompanied by subnormal temperature. The most marked, persistent, subnormal temperatures are, in my experience, found in mitral disease of the heart, especially stenosis with moderate failure of compensation.

Renal cases of severe enough type to require hospital treatment often show this condition. Cancer in its later stages may or may not; and, in my experience, tired women, and those whom we sometimes call neurasthenics, rarely show the subnormal, even during the periods of prolonged rest.

Of the other forms of tuberculosis, tuberculous peritonitis may or may not have subnormal temperature. In the cases I have followed, I have not been impressed with its frequency as a special sign to be depended upon in diagnosis.

Cases of bronchiectasis and fibroid phthisis, and cavity formation after non-tubercular infections, all of these interfering with the action of the lung, can give rise to prolonged subnormal conditions; but these are not the cases where this range of temperature comes into active play as a help in diagnosis.

Dr. B. G. R. Williams (of Paris, Illinois), has reported that he had observed a form of "grip" where there was a persistence of temperature of from 94° to 97° F., with marked depression. In the cases usually called "grip" or "influenza," my general experience has been that the return to normal has been moderately rapid. In correspondence with Dr. Williams, he states that he has not noticed so far that the cases in which he has noted subnormal temperature had developed active tuberculosis. It goes without saying that in doubtful cases everything must be taken into consideration when one sees his patient and makes his diagnosis. Cardiac and renal conditions must not be allowed to escape notice, and must be surely eliminated before the subnormal temperature alone assumes special importance; and then it must be borne in mind that there is the possibility that convalescence from various bacterial infections may be found to have periods of subnormal temperature which must make us careful in our diagnosis, although personally I do not believe that they enter into consideration to any great extent. And I say this, in spite of the statement in Krehl's "Clinical Pathology" that subnormal temperatures are more common than is generally supposed. They are often seen during convalescence from infectious diseases; and in such instances they are generally due to a diminished production of heat with an inefficient heat regulation.

PYORRHŒA DUE TO ORGANISMS OTHER THAN AMŒBAS.

By GEORGE HOWARD HOXIE, A.M., M.D.,
Kansas.

SINCE the publication of the work of Bass and Johns on pyorrhœa, there has seemed to be a tendency among dentists and many medical men to administer emetin in all cases of dental infections without establishing the presence of the endamœba. That the endamœba is not the cause of all cases diagnosed as pyorrhœa by competent dentists is shown by the history of such cases as that outlined below. Its publication (a) at this time seems, therefore, justified.

History.—A. L., man, æt. 18, high school student, first seen August 2nd, 1912, complained of attacks of sore mouth complicated by fever, ear-ache and knee pains. The family history was negative except for tuberculosis in the second generation on the mother's side (no contact). The patient had been a healthy infant until three months of age, when he had otitis with a purulent discharge. The sore mouth began at the age of three years, when the attacks began suddenly and recurred every three weeks. He had the usual children's diseases, but was in spite of it all a healthy-appearing child.

Present Illness.—A febrile attack of stomatitis, glossitis, or gingivitis (or all three) occurs every fourteen days and lasts from three to five days, ending with the removal of one or more necrotic

nodules about one-eighth inch in diameter. His ears "break" and "run" at longer intervals (for example, four times in the last seven years). His left knee swells up and pains him about five days from every four to eight weeks.

The attack begins with a general malaise and fever, followed by a soreness of the mouth, gradually localising into a swelling of the mucous membrane of the particular part affected. In the centre of this area develops a raised nodule, red, hard, but not very tender. This can be seized with forceps and pulled out at the end of from three to five days without much discomfort to the patient, leaving a clean granulating surface. No distinct scar is left. The attacks recur without reference to habits, time of year, or food. The knee attacks began last year.

Examination.—The patient is a sturdy young man, self-controlled and showing no neurotic stigmata. The weight varies from 142 to 150 pounds. Systolic blood-pressure, from 150 to 138. Chest shows some roughened respiratory sounds. Heart sounds loud and sharp. Lymph glands palpable in neck, axilla and groin. (The cervical glands swell at the time of the attacks.) Spleen not palpable. Ears negative except for scars on membrane. Nasopharynx red and "sticky." Mouth shows about half of the teeth gone and some of the remainder loose. The inflammation about the teeth has gradually destroyed the alveolar processes of most of the teeth, so that the roots are exposed. In some cases pus exudes from the socket on pressure, but in most cases none appears, because of the frequent cleanings at the hands of the dentist. Left knee shows now little or no inflammatory disturbance.

August 12th, 1912, the lower lip was swollen and red. Attack began two days ago. The right ear was discharging. Malaise was still increasing; pulse, 108; temperature, 101°. Bad taste in mouth. Pain in right ear, lip, gums. Tongue flattened and coated with a glairy membrane that could be washed off with an astringent spray, leaving a reddened and glossy mucosa. Culture from ear showed a small diplococcus.

In the interval following this attack the patient was given a course of "rheumatism phylacogen." No result, beyond the temporary chills and malaise.

Following his next attack, a course of stock staphylo-streptococcic vaccine was given (a course of autogenous vaccine had been given eighteen months previously). The following attack (October 2nd) was almost free from the constitutional symptoms, and only one nodule appeared; the next attack, however, was about as usual (October 22nd). The vaccine treatment was continued, but without distinct effect. Attacks were at their height November 6th, 13th, and 27th. The bacteriologic study of this last nodule showed long red rods and various cocci. December 2nd, an autogenous vaccine (Hecker) was started. In spite of this an extraordinarily severe attack occurred from December 14th to 18th.

January 11th, 1913, the patient was just over a week's attack; fever to 101°; two ulcers on left side of tongue, one on lip, one on buccal-gingival fornix; all on left side of mouth. In this attack the invasion was slow and stopped for two days. Interval between attacks now sixteen days.

January 17th, there was "rheumatism" of left knee and fingers of left hand. This cleared up in three days, but the knee was more or less sore in the evening for a month.

The last attack of otitis occurred January 25th, and lasted only two days.

March 15th, a culture made from the depths of a freshly-pulled necrotic plug showed on potato

(a) *Journal of the American Medical Association*, November 27, 1915.

in twenty hours a mould—a closely-felted, adherent white growth with black spot in centre; small branching colourless mycelia with conical spores. On blood serum, a looser growth, mycelia white, sporangia yellowish. On agar the growth was white with ovoid spores, but when transplanted to potato became black (*Aspergillus niger*). In glucose bouillon, filaments (*leptothrix?*) with vibrio-like forms.

April 4th, a culture from material from the depths of the ulcer immediately after the nodule had been pulled out in glucose bouillon showed chains of minute spore-like bodies and a few cocci.

April 17th, the pseudomembrane on the tongue showed mycelia under the microscope.

May 31, the "rheumatism" that had been prevailing since May 23rd stopped when the plug developed in mouth yesterday.

After attempting to eradicate the sores by curettage and caustics, it was found that the nodules appeared about the tooth-sockets or on the parts of the tongue coming in contact with the bad teeth.

October 29th, 1913, culture from the bottom of a plug showed a rich growth of *Aspergillus fumigatus*. But a smear from the same plug showed masses of a minute diplococcus, and through them threads smaller than an ordinary mycelium, which stained blue with Wright's stain.

January 2nd, 1914, a tooth was extracted. From the root a culture showed a diplococcus, a staphylococcus and a streptothrix, all decolourised by Gram.

February 24th, ulcer in anal fold. Inguinal glands enlarged and tender. A sore in left buccal mucosa opposite last lower molar, and one on tongue. (Patient has had two or three of these anal ulcers before. They occur coincidentally with the oral lesions.)

March 19th, culture on blood serum from the depths of an oral ulcer grew at room temperature a rod that united in long mycelium-like branches not decolourised by Gram.

March 21st, 1914, a vaccine made from these cultures was started. This caused some systemic reaction, but seemed to bring on the knee inflammation.

May 22nd, 1914, neosalvarsan, 0.9, intramuscularly.

June 1st, 1914, new attack, as before.

August 31st, 1914, withdrew 35 c.c. of clear fluid from left knee. Culture showed a diplococcus not decolourised by Gram and the branching sporulated organism already found in the mouth.

December 15th, 1914, all his teeth except the two last molars removed. This brought on a severe attack with much hæmorrhage from the sockets, which continued intermittently until December 20th.

August 13th, 1915, the patient has been much better and has lost very little time from his University work. But the attacks still recur at seventeen-day intervals. He is now suffering from another ulcer in the anal fold.

Summarising the record, we have to do with a recurrent fever of about seventeen years' duration. The focus has been the alveolar processes and the mucosa of the mouth, from which the body has been invaded. The particular parts, aside from the mouth, which have shown evidences of infection, have been the left knee (bursitis) and the anal fold (abscesses). The length of the attacks has varied from three to ten days. The organisms most constantly found have been a diplo-streptococcus and a mould. The disease has proved resistant to arsenic (salvarsan, arsacetin and the tri-oxid), the salicylates, and other systemic and local germicides, as well as to vaccines, both autogenous and stock, as well as mixed.

The question of great interest is whether we have to do with an organism showing a cycle of from fourteen to seventeen days, or whether it is a case of temporary immunity. Repeated examinations have failed to reveal any amœbas. Animal inoculation was negative.

To me it would appear that the causative organism is one which is ordinarily non-pathogenic, but which has acquired parasitic power in the tissues of this patient.

It is perhaps needless to say that all the conventional drugs have been used at one time or another by the various physicians who have treated the patient. The dentists employed have been the best in the city. The case was worked up from the dermatologic standpoint by Dr. R. L. Sutton (a) and published under the caption, "Periadenitis Mucosa Necrotica Recurrens." The diagnosis of pyorrhœa was given by all the dental attendants, including Dr. Frederick Hecker, the author of a monograph on that subject.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

PERISTALTIC PERSUASION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your article on the above, in this week's issue, you remark in the last paragraph on the importance of the skeletal muscles of the abdominal wall as an aid to peristalsis. Herein you do a true verdict give according to the evidence.

Until the last three weeks, during which I have been confined to bed by a fracture, I had no idea of the part played by the abdominal wall muscles in the act of defecation. My left lower extremity being incapable of flexion on the abdominal wall, the action of the obliques and recti have been all but inhibited. Ordinarily I hardly know the meaning of constipation as a personal experience, but now I find the act of stool is in its effort allied to what a male mind conceives of parturition. One understands now in quite a practical way what the troubles of patients are, in whom the anterior abdominal muscles from various causes are no better than so much limp rag. Should I ever have to treat a patient for a similar lesion to my own, and who can afford a trained nurse, I should certainly see that her daily duties included massage of the abdomen, with or without the stimulation of those reflexes described in Dr. McClure's address.

I am inclined also to ask whether the whole cycle of peristalsis and defecation is so geared up together that when the action of the muscles referred to is cancelled out or weakened, there is also a diminution not only in peristalsis, but also in the secretory activity of the mucous glands of the intestinal tract. In my own case I observe that what should be an ordinary motion is often reduced to mere sheep-droppings. Moreover, a mild pill of cascarn, aloin, and podophyllin takes generally eighteen hours to set up action.

This is not, alas, a time for making of homes; but, should any reader think in the happier days to come of building a house, he would do well to have his closet fittings carried out to allow of the squatting posture being adopted. This, the normal posture for the act, powerfully aids the anterior abdominal muscles. I cannot now turn up the reference, but I well remember one writer pointing out that the constipated life often dates from the time

(a) Sutton, R. L., *Jour. Cutan. Dis.*, 1911, XXIX., 65.

when a child is promoted from its pot-de-chambre to the ordinary lavatory seat, whereon these muscles act at such mechanical disadvantage.

I am, Sir, yours truly,

DELTA.

Cambridge, February 3rd, 1916.

THE INSURANCE ACT—PANEL PRACTICE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your clever and witty contributor, "Delta"—who has the sympathy of all in his unfortunate accident, which has, however, not clouded his powers of expression—has, I think, convinced everyone that panel practitioners are not paid for each disablement case as such, but that he may get something out of the number who have not chosen a doctor. That is another matter altogether, and shows the sloppy state of finance of the Insurance Act. I drew Dr. Richmond's attention to the paragraph, but he has failed to substantiate his statement or correct your contributor, and therefore the only conclusion is that he was mistaken in his statement that "there was no truth in the statement that practitioners on the panel receive no remuneration in respect of treatment provided for insured persons in receipt of disablement benefit." Misleading statements are lamentable and do not bolster up any cause.

I am, Sir, yours truly,

JAMES HAMILTON.

Chelsea, February 5th, 1916.

HEALTH OFFICIALS AND ALCOHOL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I always consider it to be unfortunate, for the scientific aspect of the profession and its reputation for common sense among the lay public, that resolutions should be passed such as the one quoted in the MEDICAL PRESS AND CIRCULAR (January 26th, p. 86) by the Medical Officers of Health of Nova Scotia. The statements are extravagant, misleading, and could not be substantiated before a congress of scientific men with any expert knowledge of alcohol. If the resolution had been framed to read "that the immoderate use of alcohol," etc., one could not find fault with it; but the moderate use of alcohol has neither a pernicious nor injurious effect on the public health of any country.

We, as physicians, should be careful to show the lay public that we always take a perfectly impartial view on any subject, and our opinion, when given, is founded on scientific equity.

I am, Sir, yours truly,

THOMAS DUTTON, M.D.

London, W.

February 2nd, 1916.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

MEETING HELD FEBRUARY 2ND, 1916.

Under the Presidency of MR. PRIESTLEY SMITH.

THE following cases were shown: Mr. J. Herbert Fisher, arterio-venous aneurysm; Mr. Arnold Lawson, coloboma of the upper eyelid; Dr. Attlee, congenital dermoid of the conjunctiva; Mr. G. H. Pooley, lymphoma of orbits.

A paper by the late Mr. George Coats was read by Mr. AFFLECK GREEVES, entitled

THE CAUSE OF THE OPHTHALMOSCOPIC APPEARANCES IN AMAUROTIC FAMILY IDIOCY.

The author, in this paper, deals with a contribution by Dr. F. E. Batten and Mr. Stephen Mayou on "Family Cerebral Degeneration with Macular Change," in which those authors state that there is a close relationship between these cases and the instances of amaurotic family idiocy, the only difference between them being that the macular region in amaurotic family idiocy shows a much more marked œdema of the internuclear layers, and therefore a white area around the macula associated with a hole or thinning of the retina at the fovea due to œdema, their conclusion being that œdema of the internuclear layers was present in both diseases, but much more markedly in amaurotic family idiocy. In the present paper the author says that for a histological study of the retina the material must be absolutely fresh, as *post mortem* changes begin two hours after death; fixation must be perfect (Zenker's solution being the best), and the method of cutting must be suitable. Coats considered that in the retina, apart from the occurrence of œdema, the macular changes show marked differences in the two diseases, and these are enumerated. He repudiates the view which had been ascribed to him that the ophthalmoscopic appearances in amaurotic family idiocy are due to coagulation necrosis. Though the particular form of chromolysis, vacuolisation, etc., which characterise family cerebral degeneration closely simulates that which is seen in amaurotic family idiocy, the underlying cause may be different; and the race selectiveness of amaurotic family idiocy should cause hesitation in identifying it with a disease which is not race selective.

MR. MAYOU, in discussing the paper, agreed that formalin, which was used in the case described by Dr. Batten and himself, was not a good fixative, but in one of the cases reported he thought the appearances could be fairly relied upon, except in regard to œdema in the internuclear layers.

MR. TREACHER COLLINS thought the paper might well have been entitled "Causes of Opacity of the Retina," as it dealt with the wider subject. In the class of case investigated by the author, he seemed to have established that the opacity of the retina was due to a change in the ganglion cells.

MR. J. HERBERT PARSONS said he had cut sections from a case of amaurotic family idiocy, and there were large œdematous spaces, similar to those in Dr. Batten's and Mr. Mayou's case, and he did not think they could be explained merely as the result of bad fixation. A good fixative, like the Zenker, might cause an artefact appearance in the opposite direction to that alleged in this paper. He regarded amaurotic family idiocy as one of the most sharply defined clinical entities known.

MR. HOLMES SPICER and MR. AFFLECK GREEVES contributed a paper on

SUPERFICIAL LINEAR KERATITIS.

The condition was one in which there were superficial ridges of epithelium raised above the level of the cornea, mostly running in vertical lines, grey and tapering, and having along their course bulging node-like appearances. They had tapering ends, and did not extend quite to the limbus. They not uncommonly showed punctate staining, but there was no iritis. The tension of the eyeball was nearly always *minus*, and during such times the vision was definitely impaired, though it recovered when the normal tension was re-established. It differed from dendritic ulcer (which it appeared to simulate), especially in the reduced tension. No measures which he had employed prevented recur-

rences. A number of drawings and microphotographs illustrated the contribution. It was discussed by Messrs. COLE MARSHALL, J. B. LAW FORD and D. L. DAVIES.

Mr. WALTER EDMUNDS read a paper on

CATARACT IN EXPERIMENTAL THYROIDECTOMY.

He said he did not think the lens opacity was due to disease of the eye itself; in the dogs dealt with the pupil was active, and there was perception of light. He thought the cataract was due to the general nutritional changes following the removal of the thyroid gland, and the fits seemed to be due to that. Similar instances had been recorded in man. The cataractous changes which he found were not of the lamellar or any special type. When the parathyroids were also removed, the animal quickly sickened and died, the death being preceded by tremors.

The paper was discussed by Messrs. HERBERT PARSONS and HERBERT FISHER, and Mr. EDMUNDS replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, NOVEMBER 26TH, 1915.

R. J. ROWLETTE, M.D., F.R.C.P.I., in the Chair.

EXHIBITS.

DR. BRONTE showed (1) A case of endocarditis with large vegetations on both mitral and aortic cusps; patient had history of frequent attacks of gonorrhoea, but sections showed Gram-positive cocci only. (2) The viscera of a young girl showing congenital absence of the left lung with displacement of heart leading to a hyaline formation of the pericardium at the point of contact of apex of heart. The intestine was gangrenous, although no thrombosis or other impediment to vascular flow was to be found. Both kidneys showed connective tissue proliferation and parenchymatous degeneration, and the liver was sclerosed and fatty.

Prof. METTAM exhibited a melanotic spindle-celled sarcoma from the prepuce of a dog. There were secondary deposits in the lungs and mesenteric glands; also in the auricles, ventricles, interventricular septum and the papillary muscles of the heart. He also exhibited the head and spleen from a case of osteomalacia and myeloid leukæmia in a bear. The subject, a female, about four or five years old, had some difficulty in swallowing during life.

At the autopsy there were numerous petechiæ found on the serous surfaces. The liver was bile-stained, though otherwise normal. The spleen was enlarged, and histologically it had the appearance of actively proliferating red marrow. Pre-myelocytes, granular myelocytes, leucocytes, megakaryocytes, and erythroblasts were numerous. Hæmosiderin pigmentation was present. The normal splenic tissue had almost completely disappeared, there being only traces of the Malpighian bodies and atrophied trabeculæ present. The thyroid appeared to be normal. The lungs showed numerous infarcts which contained normoblasts. Head Lesion:—The upper jaw was greatly deformed by two elongated curved swellings replacing the normal gums. The teeth were irregularly placed, and the interdental spaces widened. The lower jaw appeared normal but somewhat sclerosed. Opposition of the jaws was impossible. There was no softening or deformity of the other bones.

(3) Prof. METTAM also exhibited for comparison the head of a spider monkey with osteomalacia. He said he had met the condition in three other female monkeys; these cases showed softening and pliability of all the bones and there was hypertrophy and hyperplasia in the parathyroids of each, the thyroids proper being degenerated. He considered it was not improbable that excessive parathyroid internal secretion might lead to decalcification.

Dr. R. J. ROWLETTE asked whether melanotic sarcoma was of common occurrence in the dog and whether it was influenced by breed?

Prof. METTAM, in replying, said that sarcoma was common in the dog, it was not affected by breed except in the case of the so-called "infective sarcoma," which was more common in bulldogs and St. Bernards. He had recently met the condition in an Irish terrier. With regard to osteomalacia, he said it was common in the goat, and he had met two cases in pigs of one litter. The disease was comparatively common in the south-west of France. He stated that leukæmia was common in fowls and was infectious. If the spleen of a leukæmic fowl were emulsified and filtered, the filtrate would reproduce the disease when inoculated into another fowl.

Dr. BOXWELL exhibited a specimen of carcinoma of the thyroid gland. The case was reported in THE MEDICAL PRESS AND CIRCULAR of December 29th, 1915, p. 605.

Dr. R. J. ROWLETTE commented on the presence of connective tissue in the tumour mass in the vena cava. He regarded cancer as consisting of two elements, the epithelial tissue and the connective tissue, the preponderating element in different cases depending upon the rapidity of its growth; when rapid, the epithelial element preponderated; when slow, the connective tissue was more in evidence.

Prof. METTAM said that goitre in animals had a marked tendency to invade the thorax. He asked was there any evidence of sarcoma? As to the origin of connective tissue in an epithelial tumour, he stated that when cancer with its supporting stroma was inoculated experimentally, the connective tissue disappeared, whereas the epithelial part continued to grow, favouring the view that the connective tissue of cancer was a secondary and not a primary element of the tumour.

Dr. BOXWELL, in reply, said that no sarcomatous element had been found. He considered it was very remarkable that the tumour was growing in the blood stream in the vena cava and it quite upset his preconceived ideas as to the vitality of cancer cells in the blood; he could not explain the presence of the connective tissue in this part of the specimen.

Dr. T. T. O'FARRELL exhibited photographs and microscopical sections of a case of melanotic carcinoma (alveolar sarcoma) of the foot. The patient, a woman, æt. 75, was always quite healthy except for some uterine condition which necessitated an operation in April, 1913. In May, 1915, a black mark appeared beneath the little toe of the left foot; it gave her little trouble till July and August when further spots appeared on the shin; in October a lump appeared in the groin. She was admitted to hospital, but owing to the rapid formation of these metastases and the age of the patient it was considered inadvisable to operate. The primary growth was about the size of a Tangierine orange, was darkish in colour, but otherwise not unlike an epithelioma. The secondary deposits around the lower third of the leg were mainly subcutaneous, some having the appearance of small black marbles; there were more black spots up the

leg and thigh. Sections made from one of the marble-like deposits showed a layer of squamous epithelium beneath which was some fibrous tissue in which were lymphatics filled with tumour cells, and underlying this was solid tumour substance of alveolar sarcoma (carcinoma). The melanin pigment was deposited as a layer in the more superficial cells of the tumours, some pigment being present in the connective tissue directly beneath the squamous epithelium.

(2) Dr. T. T. O'FARRELL also showed a chorion-epithelioma malignum which had been previously exhibited at the Obstetrical Section of the Academy on November 19th, 1915, by Dr. A. Smith. The patient, æt. 40, had had many children. She aborted in December, 1914, during the tenth week of pregnancy; subsequently there had been a heavy foetid discharge. The uterus was removed by operation in October, 1915. There was no evidence of metastases. The specimen measured: height, 11 cm.; breadth, 10 cm.; thickness, 7 cm. The dilated cavity of the uterus was occupied by a large, spongy, hæmorrhagic mass; on section, the latter was seen to be directly connected to the uterine wall, but somewhat free towards the cervical end. Microscopical sections showed three more or less distinct zones: namely, the outer muscular wall of the uterus; an inner of laminated septic blood clot infiltrated with polymorphonuclear leucocytes; and an intermediate comparatively thin zone of tumour cells. The neoplastic zone showed two distinct types of elements:—(1) One consisting of rather darkly staining multinucleated protoplasmic masses which in places appeared as large giant cells, but in others lengthened out into bands of varying thickness which followed the line of blood clefts—syncytial protoplasm; (2) The other element consisted of clear distinct cells, partly vacuolated and containing rather faintly staining nuclei—Langhans' cells. The tumour substance was seen to invade blood spaces and the muscular tissue. There was no decidual or glandular tissue present, the tumour directly impinging upon and infiltrating the muscular structure.

He briefly discussed the present theories as to the formation of these and like tumours and their classification as heterochthonous blastomata.

Dr. R. J. ROWLETTE said that in his experience chorion-epithelioma was rare in Dublin; he could recall only four recorded cases. The tumours were described as being of three types:—(1) Containing only the Langhans' element; (2) containing both syncytial and Langhans' elements; (3) containing both the above plus definite chorionic villi. He had met a case of the first type, there being secondary deposits in the vagina and lungs.

MR. WILLIAM WALLS, of Southport, retired surgeon, left £28,351.

MISS CLARE HELEN THORNTON, of Regent's Park, left £200 to the Alexandra Hospital for Children with Hip Disease.

DR. A. T. DE MOULPIED, District Inspector for the elementary schools in Greenwich, Lewisham and Woolwich, having joined His Majesty's Forces, Dr. P. B. Ballard will take control during his absence.

DR. PASK, one of the Lancashire County Council's Senior Tuberculosis Officers, who has returned to his duties after a year's absence with the colours, has been appointed Medical Superintendent of the High Corley Sanatorium at a salary of £450 per annum. Before his present appointment Dr. Pask was Medical Superintendent to the Salterley Grange Sanatorium, near Birmingham.

SPECIAL REPORTS.

AWARDS TO MEDICAL MEN FOR SERVICES IN THE FIELD.

A SPECIAL supplement of the *London Gazette* contains the latest list of awards for services in the field and in connection with nursing.

ORDER OF THE BATH.

The King has been graciously pleased to give orders for the following appointment to the Most Honourable Order of the Bath, for services rendered in connection with military operations in the field. To be Additional Member of the Military Division of the Third Class, or Companion, of the said Most Honourable Order:—

Australian Force.—Lieutenant-Colonel Wilfred Wannostrocht Giblin, Australian A.M.C.

ST. MICHAEL AND ST. GEORGE.

The King has been graciously pleased to give directions for the following appointments to the Most Distinguished Order of St. Michael and St. George, for services rendered in connection with military operations in the field. To be Additional Members of the Third Class, or Companions, of the said Most Distinguished Order:—

Colonel Charles Henry Hale, D.S.O., A.M.S.
Australian Force.—Lieutenant-Colonel Albert Hobart Sturdee, Australian A.M.C.

DISTINGUISHED SERVICE ORDER.

Major Walter Rothney Battye, M.B., F.R.C.S., I.M.S.

Major Dudley Sheridan Skelton, R.A.M.C.
Captain Edward Selby Phipson, M.B., I.M.S.

MILITARY CROSS.

Temporary Captain James Heslop Aikman, M.B., R.A.M.C.

Temporary Captain George D'Rastrik Carr, R.A.M.C.

Captain Charles Conway Fitzgerald, R.A.M.C. (T.F.).

Captain Frederick John Henry Tobias Frere, M.B., R.A.M.C., Special Res.

Captain William Rutherford, M.B., R.A.M.C. (T.F.).
Temporary Lieutenant Harold Benge Atlee, M.D., R.A.M.C.

Australian Force.

Captain Edward Thomas Brennan, Australian A.M.C.

Captain Clyde Wentworth Thompson, Australian A.M.C.

OBITUARY.

SIR F. H. LOVELL, C.M.G., F.R.C.S., LONDON.

SIR FRANCIS HENRY LOVELL, Dean of the London School of Tropical Medicine, died in London on January 28th, in his 72nd year.

Educated at St. Bartholomew's Hospital, he qualified M.R.C.S. in 1865 and L.S.A. in 1867. He was Colonial Surgeon of Sierra Leone, 1873-1878. Here he saw for himself how terrible were the effects of fevers of the malarial and yellow type. He became Chief Medical Officer of Mauritius and member of the Legislative Council, 1878-1893; later he was appointed Surgeon-General of Trinidad and Tobago and a member of the Executive and Legislative Councils, 1893-1901. He retired from the Colonial Service in the latter year, and in 1903 was appointed Dean of the London School of Tropical Medicine. In 1909 he paid a visit to the West Indies with the object of interesting some of the Colonies in the work of his school, and also of enlisting their support for this great enterprise. He visited Barbados, the Windward Islands, the Leeward Isles, Jamaica, Trinidad, and British Guiana. From a financial point of view also the tour was a success. Sir Francis was anxious to have sufficient funds to conduct research work adequately and to be able to send out expeditions to the Tropics when occasion arose. This object he realised.

Sir Francis was created C.M.G. in 1893 and knighted in 1900.

LIEUTENANT-COLONEL STANLEY BOYD,
F.R.C.S., R.A.M.C., LONDON.

LAST week we recorded the death of Mr. C. Stonham, surgeon to Westminster Hospital. To-day we have to announce the decease of another well-known London surgeon, Mr. Stanley Boyd, which occurred on February 1st at his residence, 134 Harley Street, W. Like many of the hospital surgeons, Mr. Boyd had been granted a commission in the R.A.M.C. (T.F.), and held the rank of Lieutenant-Colonel. Stanley Boyd received his professional training at University College Hospital, and graduated M.B., B.S.Lond., with honours, in 1879, taking the F.R.C.S. in 1881. After holding various house appointments at his old hospital, he became a member of the staff at Charing Cross, and at the time of his death was surgeon to the hospital and lecturer on clinical surgery. He had been examiner in surgery at Cambridge University. He contributed extensively to surgical literature. His death, at the comparatively early age of 59, will be regretted by a wide circle of friends, both in and out of the profession.

DR. JOHN HUMPHRY, M.R.C.S., L.S.A.,
READING.

THE death has occurred of Dr. John Humphry, who for over 50 years was medical superintendent to the Bucks County Asylum, Stone. Born in 1822, he was educated at University College Hospital, and qualified as M.R.C.S., L.S.A., in 1849. After spending two years at the London Fever Hospital and five years at Birmingham Union Infirmary, he went in 1855 to the Crimean War as a civilian surgeon in charge of a hospital at Renkioi in Asiatic Turkey. In the following year he was appointed medical superintendent at Stone, which position he occupied until the beginning of 1908. During that period the number of patients for whom accommodation was provided increased from 200 to 700. On the completion of 50 years in office Dr. Humphry received from the Visiting Committee, members of the Bucks County Council, and other gentlemen in the county an illuminated address with a service of plate.

DR. T. J. WEBSTER, M.R.C.S., L.S.A., J.P.,
MERTHYR.

THE death has occurred at Merthyr of Dr. Thomas James Webster, M.R.C.S.Eng., L.S.A., at the age of 72 years. Deceased qualified M.R.C.S., L.S.A. in 1865, and in the early seventies commenced practice at Merthyr. For several years past his only son, Dr. Vivian Webster, had been in partnership with him. The late Dr. Webster was for many years a justice of the peace for the county. He is survived by his widow, son, and five daughters.

DR. H. D. PITT, L.R.C.P., L.R.C.S.,
WEST SMETHWICK, BIRMINGHAM.

THE death occurred on 3rd February at West Bromwich, of Dr. Herbert D. Pitt, who had been ill only a short time.

Dr. Pitt, who was educated at Birmingham and Edinburgh, qualified L.R.C.P. and S. in 1901. He was well known in connection with the St. John Ambulance work, and was medical officer in connection with classes at a large works in the district. Of late years he took the greatest possible interest in the voluntary aid detachment of the Red Cross Society, and his contingent at West Smethwick was first in the county of Staffordshire to be recognised by the War Office.

Since the outbreak of war the detachment has contributed largely to the R.A.M.C.

DR. KINGSLAND, M.R.C.S., L.R.C.P., SMALL
HEATH, BIRMINGHAM.

DR. ALFRED KINGSLAND, of Small Heath, has died from a fracture of the base of the skull following upon a fall at his home. He was a member of a very old Birmingham family. He was educated at

King Edward's Grammar School and at Queen's College, Birmingham, and qualified M.R.C.S. and L.R.C.P. in 1890. Dr. Kingsland was 49 years of age and leaves a widow.

DR. HOWARD SMITH, OF KELSO.

By the death of Dr. Samuel Howard Smith, at a late hour on Friday, January 31st, Kelso has lost one of its outstanding personalities. For eight years Dr. Smith, who was a native of Cheshire, had been intimately connected with the life of the Tweedside community, to which he first came as assistant to the late Dr. Turnbull. He was a Licentiate of the Colleges of Edinburgh and Glasgow. Among other positions in Kelso he was Medical Officer for Kelso, Makerston and Ednam, Public Vaccinator and Medical Officer for the School Board, and was the Visiting Surgeon for the Cottage Hospital. Besides discharging these varied duties in exemplary fashion, he found time to be healthily interested in all forms of sport in a sporting district. He will be sadly missed in the countryside.

LABORATORY NOTES.

"BYNOGEN" (Messrs. Allen and Hanburys, Ltd).

A SAMPLE of this preparation has been forwarded to us by Messrs. Allen and Hanburys, Ltd. "Nerve Foods" containing casein and glycerophosphates have been largely advertised of recent years. The composition of "Bynogen" suggests that it possesses marked advantages as a tonic food. It contains pure soluble milk protein, together with the glycerophosphates of lime, soda, and magnesia in combination with specially prepared dextrin-maltose. We consider the addition of the malt product a distinct advance. It renders the product easy of assimilation, and largely increases its nutritive and tonic value. Moreover, it ensures palatability—no small matter in the class of case in which "Bynogen" is indicated.

We find that "Bynogen," which is in the form of a fine powder, mixes readily with milk and with water. It can, of course, also be taken alone or mixed with other foods.

"LYCRYL" (Eucryl, Ltd., 61-63, Lant Street, S.E.).

This preparation is also designated the "All-British Lysol." Lysol had a well-deserved reputation as an antiseptic of high surgical value, and from our experience we do not hesitate to say that "Lycryl" will be found equally effective. It contains a high per cent of obesity in general, except in so far as the fatness centage of free cresols, from which have been removed the corrosive and irritating elements. It mixes well with water, forming in half to one per cent. solution an excellent antiseptic for general surgical or obstetric purposes.

MEDICAL NEWS IN BRIEF.

Glasgow Infant Health Visitors' Association.

THE annual report of the Glasgow Infant Health Visitors' Association states that there were 7,336 attendances on the doctor at the infant consultations. At the dinner table for nursing and expectant mothers there is a daily attendance of from 20 to 30, and a marked improvement in the health of mothers and children has been noted. Applications for milk in 1915 numbered 184, compared with 416 in 1914. The difference is stated to be due to the fact that work is plentiful and wages good, and also to the Government allowance to soldiers' wives and the operations of the Soldiers' and Sailors' Families Association. The Advisory Committee have attended to all necessitous cases, and many mothers and babies have improved in health as the result of the help given. Details are given of the work carried on by the 19 branches of the association, which has over

400 voluntary visitors. The infants under visitation numbered 5,684, as compared with 5,429 in the previous year. The number visited until they attained the age of one year was 2,051, as compared with 1,664 in 1914.

War Bonus for Doctor.

At a meeting of Caersws Board of Guardians (Mont.), Dr. W. Llewellyn Davies was appointed Medical Officer for the Llanidloes district in succession to Captain R. J. Jones, who is now with the R.A.M.C. The salary paid to Dr. Jones was £60, and Dr. Davies, the only applicant for the post, asked £90. A committee who met him and came to terms recommended that he be appointed at a fixed salary of £70, with a war bonus of £15 for two years. This was adopted.

Hospital Saturday Fund.

At an extraordinary meeting of the board of delegates of the Hospital Saturday Fund, over which Sir T. Vezey Strong presided, it was reported that the following grants had been made during the last year:—

	£	s.	d.
37 General hospitals	14,217	0	0
21 Cottage hospitals	681	0	0
77 Special hospitals	11,354	0	0
33 Dispensaries	386	0	0
19 Convalescent homes	1,615	0	0
25 Nursing institutions	464	0	0
11 Miscellaneous (including ambulance, distribution, and surgical appliance committees)	6,323	17	11
Total	£35,040	17	11

Mr. J. H. Dille, hon. secretary of the Distribution Committee to the board of delegates, said that the collection for 1915 amounted to £36,796. This was almost a record collection, reaching within £150 of that for 1911, when the highest collection was made. It was most gratifying that such should be the case when the many disturbing influences and the calls upon the generosity of the public for other purposes were taken into consideration. Owing to many hospital wards being reserved for, or filled by, sick or wounded soldiers who had suffered for King and country, still greater efforts were required by those at home to help the hospitals in their endeavour to provide treatment for the sufferers, and to show them that those at home appreciated their services.

Grants amounting to no less than £35,000 had been assessed, an increase of £7,000 on the sum awarded the previous year, and of £1,000 on that awarded in 1911. The sum of £35,000 included £3,350 awarded as a war bonus to those hospitals which had been succouring our sick and wounded soldiers.

The differences in the awards were brought about by the varying expenditure of the institutions and the amount of money available for distribution.

Thirty-seven general hospitals absorbed £14,217, an increase of £5,745 on the sum granted in 1914. This was mainly owing to the war bonus. The number of wounded soldiers treated in the latter part of 1914 was 11,079, and the Government paid to nine hospitals the sum of £15,058 for the accommodation provided. The average cost of each bed per week in the general hospitals on the list last year was £1 16s. 8d. This year the cost had increased to £1 17s. 9d., an increase of 1s. 1d. per week. The out-patients attending these hospitals numbered 1,045,015 in 1915, against 1,114,457 in 1914, a decrease of 69,442 (largely owing to the National Insurance Act and the number of men in the services).

The amount allotted to the special hospitals was £11,354, as against £9,943 in 1914.

The report was unanimously adopted, and Sir Vezey Strong, in commenting upon its admirable character, said that while at the very beginning of the war people were perhaps inclined to cut down their subscriptions to hospitals and similar institutions, he believed they were now giving away more than they ever did before. They regarded it as

the best way of doing their "bit," and the best appreciation they could give of the heroic work which was being done for us at home by our gallant soldiers at the front. To an inquiry as to whether the admission of soldiers in the general hospitals had interfered with the work being done for the general public, a reply was given in the negative. The chairman added that the boards of the hospitals had shown willingness, even eagerness, to receive to the utmost of their powers every suitable case which presented itself for hospital assistance.

New V.A.D. Rules.

THE latest development in the scheme for the employment of women in the military hospitals has given official recognition to the advantages of the trained over the comparatively untrained in the grading of pay. The terms of service have also been altered, twelve months being the minimum instead of the six months originally stipulated for after a month's probation.

The demand for trained women is the most important part of the scheme as it now stands. Even the assistant cooks must have some training. While those applying for posts as clerks need not know shorthand and typewriting, they must have some business training. They must be able to deal with the daily abstracts of food sent down from the different wards.

The requisitions from the War Office are not at present very heavy, but this may change at any moment. Already there are over 2,000 V.A.D. members employed on "general service," and a large number are waiting the call. The greatest difficulty is in finding suitable dispensers.

Bradford's Declining Birth-rate.

At the annual meeting of the Bradford Chamber of Commerce, held on February 1st, Mr. J. H. Robinson, president, stated that it was rather strange that simultaneously with the increase of educational facilities there should be a serious diminution of the birth-rate. Comparing 1871 with 1891, 20 years after the passing of the Education Act, the birth-rate in Bradford had fallen 24 per cent., and from 1891 to 1911 there had been a further decrease of 34 per cent. The decline in the country had not been so marked, he was happy to say, the decrease in the first 20 years being something like 10½ per cent. for the whole of the country, and for the latter 20 years 22½ per cent. Bradford, therefore, appeared in a very unfavourable light, and the matter was serious, as it meant a shortage of employees. There was much talk about what people would do after the war, but he thought there would be plenty of work for everybody. That question of the decline in the birth-rate was, in his opinion, of sufficient importance to command special investigations; there had been Royal Commissions appointed to deal with less vital problems.

Saffron Walden Isolation Hospital Superintendent.

At a meeting of the Saffron Walden Joint Hospital Board on January 19th, the Clerk read some correspondence which had passed since the last meeting with the Local Government Board as to the appointment of a Medical Superintendent of the Isolation Hospital. On November 15th the Local Government Board wrote stating that they understood that the Saffron Walden Joint Hospital Board had recently had under consideration the question of the appointment of a Medical Superintendent, and that it had decided to take no action at the present time. In that connection the Local Government Board must remind the Joint Board of the correspondence on this subject when the loan for the new buildings was granted, and they asked to be furnished with the Joint Board's observations upon it. In reply to that letter the Clerk wrote stating that he had submitted their letter to the Chairman of the Joint Board, who had instructed him to reply thereto stating that the Joint Board felt that, having regard to the circular issued by the Local Government Board on the necessity for economy in public expenditure, and that every effort should be made to reduce the local rates,

it was incompetent to proceed with the creation of a fresh office at the present time, and that the duties could be adequately discharged by the local medical men in charge of the cases sent to the hospital. The new buildings had cost £3,000, which expenditure would probably not have been sanctioned under present circumstances, and £390 had also been spent on a joint small-pox hospital for North Essex; and the Joint Board regarded the present time as most inopportune to add to its financial responsibility. If the same conditions were now existing as at the time the loan was granted, the Joint Board would not have hesitated to carry out the proposal. In reply to that letter, the Local Government Board wrote stating that it was very desirable that some officer should be responsible for the medical superintendence of the hospital, but under the present circumstances they would not press the matter further, but would expect the Joint Board to carry out its undertaking as soon as circumstances permitted.

Measles Epidemic at Crewe.

DR. A. B. M'MASTER, Medical Officer for Crewe, in a report to the Health Committee, says measles in the borough has been of a particularly virulent type. One hundred and thirteen cases were notified from the schools, and during the three months just ended 29 deaths were due to the disease.

Consulting Surgeons at Leeds Workhouse.

THE Leeds Board of Guardians propose, subject to the sanction of the Local Government Board, to appoint consulting surgeons at the Beckett Street Workhouse. If the proposal is carried out, the Guardians will be able to call upon the services of the most skilled consultants, paying, of course, the consultants' fees, for any inmates of the workhouse infirmary, and the Medical Superintendent of the infirmary will decide not only in cases of general surgical operations, but in those of throat, eye, nose, and ear affections, and in difficult midwifery cases, whether one of the specialists whom the Board will nominate shall be summoned. A new operating theatre has recently been constructed at the infirmary, and an X-ray apparatus is to be installed there.

Birmingham University.

THERE was a decrease of 246 students at Birmingham University last session, compared with the previous session, the total number of registered students during the past year being 786. At present 65 members of the staff and 255 students are serving in His Majesty's forces or in hospitals. In addition five past members and 223 past students are taking part in military service.

A Hospital Doctor's Liability.

A CASE of interest to medical men was heard at Woolwich County Court on 26th January, before his Honour Deputy-Judge Lush.

Herbert Barnett, dispenser, of Red Lion Lane, Woolwich, sued Captain Valentine Goode Johnson, commanding the R.A.M.C. at the Royal Herbert Hospital, for £5, being £2 2s. for one week's wages in lieu of notice, and £2 18s. for expenses incurred by the non-return of plaintiff's original testimonials.

Plaintiff said he was discharged from the Royal Herbert Hospital on the day before Christmas at a moment's notice. He was employed in the hospital dispensary, and sued Captain Johnson as chief officer at the hospital.

Captain Johnson said he was in no way responsible in this matter. The dispensers were civil employees under the War Office, and were under contract rates fixed by the Secretary of State for War. Presumably the real employer was the Secretary of State for War, but the officers in charge of the hospitals all over the country had powers delegated to them to engage these men. Witness was not the officer in charge of the Royal Herbert Hospital; he was the officer commanding the R.A.M.C. Company there, and, as far as he knew, had nothing to do with this matter.

His Honour said this was clearly a Government matter, and it was quite clear that Captain Johnson

had nothing whatever to do with it. Plaintiff would therefore be non-suited, and Captain Johnson was entitled to costs.

Captain Johnson said he had incurred no costs other than travelling expenses, and he did not wish to trouble about these.

Harrogate Infirmary.

THE annual meeting of the Harrogate Infirmary Governors and subscribers was held on January 29th. The Committee in their report stated that during the year 200 patients had been received in the ward opened for invalid soldiers, and that the work had been highly appreciated by the military authorities. Since last year further contributions had been received which, with the sum paid by the War Office, amounted to £775. The cost of maintenance of the soldiers and other expenditure to December 31st, 1915, was £560, leaving a balance of £215 towards the expenses of the current year. The general revenue account, which showed a debit in 1914 of £2,486, had been increased by the sum of £409. The deficiency on the revenue account of 1915 now stood at £2,896.

Health and War.

THE first meeting of an important International Commission was held in Paris on February 2nd. The Commission represents an endeavour on the part of the Allies to systematise and co-ordinate their joint efforts in regard to the sanitary and hygienic problems raised by the war.

The Chairman is Dr. Santo Liquido, a member of the Italian Parliament, well known as an authority on questions affecting public health.

Royal College of Surgeons of England.

TO-DAY (Wednesday) at 5 p.m., Professor J. Ernest Frazer, F.R.C.S., will deliver the second Hunterian Lecture on "The Development of the Structures Associated with the Roof of the Early Mouth Cavity," and on Friday next, February 11th, Professor W. Blair Bell, B.S., M.D., M.R.C.S., will deliver the third, on "Experimental Operations on the Pituitary Body," at the same hour.

A course of lectures on the "Anatomy of the Human Body" will also be given for first-aid and ambulance students, by Professor Arthur Keith, at 5.30 p.m. on the following dates:—On every Monday, Wednesday and Friday, from the 14th to the 25th, and the same days in March, from the 13th to the 31st.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s. post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer not necessarily for publication, but as evidence of identity.

A FELLOW FEELING.

AN officer of the Royal Flying Corps while at home on leave from the front was invited to join a party for a couple of days' shooting in the country. "Oh, no, no, thanks," he replied with emphasis. "I've not the heart for it. I've been the blooming bird myself."—*Liverpool Post*.

NOVEL (Wigtown).—The University Court of St. Andrews states that in comparison with last year the total number of students matriculated for the Martinmas term showed a decrease from 416 to 350, the number of men students a decrease from 232 to 144, and the number of women students an increase from 184 to 206.

X. Y. (Torquay).—The annual report of Plymouth Royal Eye Infirmary states that during the year 1915, 2,319 new patients had applied for treatment.

LAUNDRIES AND THE WAR.

"We are eight million double collars short every week," said a man in the laundry trade, giving evidence at Clerkenwell County Court, and lamenting that no business had suffered through the war like laundries.

ALLOTMENT (Exeter).—We hope to publish an account of the meeting.

ELECTRIC (Gateshead).—It is stated that in the last three months of 1915, 1,134 claims against the London County Council in respect of tramway accidents were settled at a cost of a little over £10,000. In 14 out of 35 other cases verdicts were given against the Council, and these cost £634 15s.

JUST HEARD OF THE WAR.

SPEAKING at Eastbourne, the Rev. E. T. Greenshield, a missionary, said his parishioners in Baffinland, North-West Canada, had only just heard there is a war on.

IXION (Camberwell, S.E.).—The births registered in London for the week ending Jan. 29th numbered 2,023, and the deaths 1,203.

"VIVE L'ENTENTE!"

MAIDSERVANT (at the back door): "If you know vot we 'ave, why can't you leave it on the winderledge, same's the milk does?"

BAKERESS (taking over soldier brother's round): "My brother said as you always come to the door here."

MAIDSERVANT: "Hol did 'e—, Well, it's a case of 'hotres toms hotres mewers'—as our gallant Hallies says!"—*The Bystander*.

ESSEX DOCTORS AND THE WAR.

At a meeting of the Essex Insurance Committee on January 25th, it was reported that two more panel doctors were joining the R.A.M.C., making a total of 60 practitioners absent from the county on military duties.

TROMMER MALT AND OTHER PRODUCTS.

In reply to recent enquiries, Messrs. Francis Newbury and Sons, Ltd. (who are sole distributors of the products of the Trommer Co., Ltd.), inform us that these are, without exception, of British manufacture, and that none of the company's shares are, or have at any time been held by alien enemies.

Meetings of the Societies, Lectures, &c.

TUESDAY, FEBRUARY 15TH.

ROYAL SOCIETY OF MEDICINE (1, Wimpole Street, W.).—5 p.m.: General Meeting of Fellows. Ballot for the Election of Candidates to the Fellowship.

ROYAL SOCIETY OF MEDICINE (SECTION OF MEDICINE; AND THERAPEUTICS AND PHARMACOLOGY) (Joint Meeting) (1, Wimpole Street, W.).—5 p.m.: Dr. Hale White (President of the Section of Therapeutics and Pharmacology) in the Chair. A special discussion on "Trench Nephritis" will be opened by Dr. Langdon Brown, Sir William Osler, Sir Wilmot Herringham, Mr. Mackenzie Wallis, Dr. Galloway, Dr. R. G. Abercrombie, Dr. R. A. Chisolm, Dr. W. Mair will speak. N.B.—Members of other Sections interested in the subject are specially invited to be present.

WEDNESDAY, FEBRUARY 16TH.

HUNTERIAN SOCIETY (1, Wimpole Street, W.).—9 p.m.: Annual Oration. Dr. A. S. Currie: The Spirit and Inspiration of William and John Hunter.

ROYAL SOCIETY OF ARTS (John Street, Adelphi, W.C.).—4.30 p.m.: Paper. Prof. J. A. Fleming: The Organisation of Scientific Research.

ROYAL SOCIETY OF MEDICINE (SECTION OF THE HISTORY OF MEDICINE) (1, Wimpole Street, W.).—Papers. Mr. C. E. Wallis: Marat. Mr. Percy Dunn: An Oculist of XVII Century (Andreas Laurentius). Dr. Dan McKenzie: Folk Cures by Constriction and Rings, with a discussion into the Nature of the Soul. Dr. C. G. Cumston (Geneva): Portrait of Paracelsus.

Vacancies.

The Princess Club Hospital for Wounded (80 beds), 106, Jamaica Road, Brompton, S.E.—Resident Medical Officer. Salary £150 per annum and all found. Applications to Mr. F. L. Provis, 51, Welbeck Street, W.

West Bromwich and District Hospital.—Assistant House Surgeon, Salary £120 per annum, with residence, board, and laundry. Applications to Thos. Foley Baché, Esq., Churchill House, West Bromwich, Frank I. Hancock, Secretary.

Leeds Public Dispensary.—Lady Resident Medical Officer. Salary £130 per annum, with board, residence, and laundry. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

Royal Albert Hospital, Devonport.—House Surgeon. Salary £150 per annum, with board and laundry. Applications to the Chairman of the Selection Committee.

Liscard, Wallasey, Victoria Central Hospital.—House Surgeon. Salary £160 per annum, all found. Applications to the Secretary.

Birkenhead Borough Hospital.—Junior House Surgeon. Salary £170 per annum, with board and laundry. Applications to the Secretary.

Bury Infirmary.—Senior House Surgeon. Salary £250 per annum, with board, residence, and washing. Applications to Hon. Sec., Infirmary, Bury, Lancs.

Birmingham and Midland Eye Hospital, Church Street, Birmingham.—House Surgeon. Salary £200 per annum, with residence and board. Applications to J. W. Pearce, General Supt. and Secretary.

Appointments.

COUPLAND, W. H., L.R.C.P. and S.Edin., L.F.P.S.Glas., has been appointed Medical Superintendent at the Royal Albert Institution, Lancaster.

FRASER, C. L., F.R.C.P. and S.Edin., D.P.H., has been appointed Temporary Medical Officer of Health for Berwick Borough.

SALMON, Arthur Guy, M.D., B.S.Lond., L.R.C.P., M.R.C.S., L.S.A., has been appointed Temporary Medical Officer for the Workhouse, and No. 2 District, by the Bodmin (Cornwall) Board of Guardians.

VERHEYDEN, M. H. (Mrs.), L.D.S.Edin., has been appointed Dentist to the Scattered Homes by the Brentford Board of Guardians.

Births.

ANDREWS.—On Feb. 2nd, at Corran, Lochgilphead, Argyll, the wife of Dr. Alfred Andrews, of a son.

BARNES.—On Feb. 3rd, at 47, Gloucester Place, Portman Square, W., the wife Herbert Cooper Barnes, M.D., of a daughter.

EWART.—On Feb. 4th, at 53, The Manor House, Marylebone Road, the wife of Capt. G. A. Ewart, R.A.M.C.T., of a son.

GORDON.—On Jan. 29th, at Stanway, S. Farnborough, Efield, wife of A. Bruce Gordon, F.R.C.S.E., Temp. Lieut. R.A.M.C., of a daughter.

HILL.—On Jan. 31st, at Greenhayes, Banstead, Surrey, the residence of her parents, Mr. and Mrs. Howard Trollope, the wife of Capt. F. T. Hill, R.A.M.C., British Expeditionary Force, of a daughter.

Marriages.

BROWNING—ASHLEY SMITH.—On Feb. 3rd, at St. George's, Hart Street, London, Harold Gordon Browning, M.B., B.Ch., of Pershore, Worcestershire to Violet, elder adopted daughter of Dr. and Mrs. Ashley Smith, Codsall, Staffordshire.

JEFFRIES—BAILEY.—On Feb. 1st, at St. Mary's and All Saints, Trentham, Hugh Stephen Jeffries, Surgeon, R.N., youngest son of Mr. and Mrs. E. F. Jeffries, Market Harborough, to Jessie, eldest daughter of Mr. and Mrs. J. C. Bailey, Trentham, Staffordshire.

MCGILLYCUDDY—LUKEY.—On Feb. 3rd, at St. Cuthbert's, Wells, Lieut. Richard Hugh McGillycuddy, R.A.M.C., younger son of The McGillycuddy of the Reeks and The Madam McGillycuddy, of Bauncelune, Beaufort, co. Kerry, Ireland, to Ethel Florence, second daughter of the late Edward Lukey, Esq., J.P., of Dover, and Mrs. Lukey.

PRINGLE—HART.—On Jan. 24th, at St. Matthew's, Ipswich, Arthur Young Pringle, M.R.C.S.Eng., L.R.C.P.Lond., of Glaslyn, Crescent Road, Ipswich, to Jessie Eva Hart, M.B., B.S.Lond., youngest daughter of the late S. J. Hart, of Chatham.

Deaths.

BELEMORE.—On Feb. 4th, at Brighton, A. J. Belemore, Surgeon-Lieutenant-Colonel (retired), in his 77th year.

BOYD.—On Feb. 1st, at 134, Harley Street, W., Lt.-Col. Stanley Boyd, R.A.M.C.T., F.R.C.S., aged 59.

BRIGHT.—On Feb. 3rd, Dr. James Albert Bright, of Bedford Villa, 14, Penge Road, South Norwood, S.E., late of Glastonbury, Somerset, aged 76.

CARNT.—On Feb. 4th, Coombe Leigh, Queen's Road, Ryde, I.W., Walter George Carnt, late General Superintendent and Secretary of the Manchester Royal Infirmary, aged 55.

GARROD.—Killed by shell, in France, on Jan. 25th, Alfred Noel Garrod, M.R.C.S., Lieut., R.A.M.C., 100th Field Ambulance, eldest son of Archibald E. Garrod, M.D., F.R.S., Colonel, A.M.S., and Mrs. Garrod, of 9, Chandos Street, W., and Wilford Lodge, Melton, Suffolk, aged 28.

KIRKWOOD.—On Jan. 30th, at 1, North Street, Peterborough, George Kirkwood, M.D., aged 63 years.

MILLER.—On Feb. 4th, at Alum Chine Towers, Bournemouth, Frederick Richard, R.A.M.C.T., D.A.D., M.S., of the 60th Division, 3rd Army, son of the late T. Lanfear Miller, late of Cape Town, aged 50 years.

MONCKTON.—On Feb. 4th, at East Sheen, William Monckton, M.R.C.S., L.R.C.P., late of Portishead, Somerset, and Rugeley, Staffordshire.

WRIGHT.—On Jan. 31st, at Haddenham, Fredk. William Wright, M.R.C.S.England, L.S.A.Lond., late of Derby, aged 75.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, FEBRUARY 16, 1916.

No. 7.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravants les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

Age and Efficiency.

THE Public Health Committee of the New York Academy of Medicine recently included an inquiry into age and efficiency. Its findings are in agreement with other less authoritative investigators, who have believed that it is during the fifth decade that man is in his intellectual prime. Dr. Levinski-Corwin, the secretary of the committee, in a brief advance report, severely criticises the attitude of those pushful American business houses which have acted on the maxim that a man is "too old at forty." If we bear in mind the obvious fact that this is essentially an individual matter, it may certainly serve some useful purpose to endeavour to reach a generalisation, but it should also be recognised that climatic and racial considerations will so seriously vitiate conclusions drawn from American data as to render them practically valueless in Europe. In such matters it is impossible, even if we limit our survey to Europe, to say that what is true of the Latin races is equally true of the Scandinavian.

Age in the Cabinet

THERE has recently been a good deal of rambling chatter in the lay Press which, if it signify anything beyond ignorant discontent in search of a scapegoat, must mean that those who are responsible for the management of our affairs, whether at home or abroad, are effete senilities who ought at once to be replaced by younger men. There may be individual instances where this is true, but as a generalisation it is absurd. Of the members of the Cabinet, for example, one only, Lord Lansdowne, has reached seventy. Then comes Mr. Balfour with sixty-eight, followed by Lord Kitchener and Mr. Birrell, each with sixty-six, and the Prime Minister with sixty-four. Of the remainder, three—Sir F. E. Smith, Mr. Herbert Samuel, and Mr. Runciman—are forty-six or under; and the eldest of the other twelve is Mr. Bonar Law, who is fifty-eight. To suggest, as is occasionally done, that a body thus composed must be incompetent on account of the senility of its members is pure factious nonsense. If incompetent it be, the cause of the incompetence must be sought elsewhere. Both Lord Palmerston and Mr. Gladstone proved themselves exceedingly vigorous and resourceful when they were much

older than the oldest member of the present Cabinet.

Periodical Medical Examination.

THE above-mentioned New York Committee has started a movement whose object is the preservation of efficiency considerably beyond fifty by detecting vicious tendencies and malfunction in the early remedial stages. This is to be done by periodical thorough physical examination. "Life insurance companies are taking up the agitation as a paying proposition, because it will retard the average death-rate. An effort is being made to equip an organisation for free examination at least once a year of anybody who cares to apply. The increased working power possible of development by this scheme, it is said, will repay a thousandfold the money which the municipality or life insurance companies may decide to put into the proposition." The idea is by no means devoid of merit. But how the neurotics would enjoy themselves!

Pre-natal Conditions.

DR. LEVINSKI-CORWIN is strongly in favour of cultivating efficiency from the very beginning—that is, from the pre-natal period. The movement in this direction, which was started some years ago, has naturally received a tremendous impetus from the conditions created by the war. Sir James Crichton-Browne, who has made the subject his own, has recently delivered a lecture characterised by his usual vigorous common sense, clothed in the graceful language which we have learnt to expect from him, in which he considered some of the more pressing aspects of the matter. The excess of females over males he regards as one of the most serious problems which the immediate future will have to face. The general decline in the birth-rate is in itself serious enough, but the relative decline in males—the negative masculinity, as Sir James calls it—is a matter which urgently demands the closest attention. This attention, he opines, should be concentrated on pre-natal conditions and infant mortality. The present "negative masculinity" is due, it seems, not so much to the fact that more girls are born into the world than boys, as to the much greater mortality among the male babies than among the female. "All over the country many more boys

are dying than girls. In the rural district of Westmorland, for example, 48 boys under a year old died to 21 girls. In Wiltshire the ratio was 135 boys to 78 girls."

SUCH startling ratios as these must evidently be explicable. They cannot be due to mere chance. Of course, a great many theories have been put forward, but the most obvious one appears to have been overlooked. It is that boys, being very much more highly organised than girls, succumb much more readily to unfavourable environment. A Marechal Niel rose dies more readily than a roadside briar. That the environment of babies in the lower classes, especially in large cities, is hygienically of the most deplorable kind needs no emphasising. Nor need it be insisted upon that the decline in the maternal suckling of children, which has recently become so marked, still further deteriorates the "environment" of all babies. The unwillingness to suckle their young is due in the upper classes to selfishness; in the lower classes to the struggle for existence. In the middle classes it is due to suffragettism and other ill-balanced propaganda, which seek to persuade woman that she is something other than a child-bearing and child-rearing creature. If you would get down to the bed-rock of the decline in the birth-rate, you must study the extreme feminist movement—its theories and its practices. And Havelock Ellis might help you in your studies.

To the list of Bumbles who have been raising their ignorant voices against the L.G.B. order for the compulsory notification of measles, we must now add some of the members of the Wood Green Council. Councillor Cole is reported, in the *North Middlesex Chronicle*, to have delivered himself on this subject as follows: "It was about time that parents were allowed to keep some of their parental responsibility. The isolation of scarlet fever cases had not stopped that disease; it had simply relieved certain people of the expense of illness. This new order was a deliberate conspiracy, and would mean a cost to the national rates of millions a year. And what for? How many patients would they have in the hospital? It was a pity the Government did not get on with their war work and let the Councils alone for a time." Now, there is, on scientific grounds, a very strong case against the compulsory notification of measles, the chief of these being that the most infectious, if not the only infectious, period is past before the diagnosis can with certainty be made. We pointed out last week (p. 116) that Dr. Davies, the M.O.H. of the City of Bristol, had marshalled the arguments against compulsory notification, and had presented a reasoned and temperate report on the subject to the Health Committee. A great many M.O.H.s and practical sanitarians are in cordial agreement with Dr. Davies, and the compulsory order has received as much criticism from members of the profession as from laymen. The criticism of the profession has been considered and informed; that of the laymen has, for the most part, been ill-considered

and ignorant. Dr. Davies' report affords an excellent example of the one; Councillor Cole's remarks a typical specimen of the other.

THERE can, I think, be very little doubt that we are moving rapidly towards a State Medical Service controlled by a Ministry of Public Health armed with very extensive powers. The demand for such a Ministry has been a growing one ever since the Public Health Act of 1875 made of the Medical Officer of Health the most important functionary in the community. The Insurance Act brought the profession into still more intimate touch with the Government, and the state of chaos in which the working of that Act now finds itself is evidently due to the want of some guiding and co-ordinating authority. The Medical Officers of Health cannot for much longer be allowed to remain under the control of the butchers, bakers and candlestick makers who form the majority of local councils. The important officials upon whom the health of the community so largely depends must be combined into a regular state service, responsible to the State, through the head of a State department, removable by that head and by none other. The Insurance Act will probably require several amending Acts before it can be made to work smoothly, and the details of these amending Acts can be worked out only by a Department with the necessary machinery for obtaining the necessary knowledge. It all sounds singularly Utopian, but its advent cannot be long delayed.

IN the matter of the causes of infantile mortality, it would seem that one cause, namely, over-lying, is, in reality, less frequent than has hitherto been believed to be the case. This has been recently brought out by Dr. W. A. Brend, the distinguished Lecturer on Forensic Medicine at Charing Cross Hospital, in his thesis on "Deaths from Violence" which gained him the Gold Medal in State Medicine when graduating M.D. (Lond.). Dr. Brend is also a barrister-at-law. Dr. Brend says that in a large number of cases, over-lying is stated as the cause of death owing to the superficial nature of the *post-mortem* examination, as performed by the ordinary medical attendant. When the *post mortem* is performed by a skilled pathologist this cause of death is very seldom registered. In proof of this contention, he quotes the figures of inquests held in London on children under one year of age during 1910. In that year, out of 271 such inquests in the Central District, 68 were attributed to over-lying, and the same, or nearly the same ratio ruled in all the other London districts except two. These two were the Westminster and South-Western districts in which at that time Mr. Troutbeck officiated as Coroner. Mr. Troutbeck made it a rule to employ an expert pathologist in every case, and from his districts the rather startling fact emerges that out of 134 inquests on dead babies, only one death was attributed to over-lying. As Dr. Brend properly points out, a verdict of overlying is a very serious one for the mother, and should not be returned except as the

result of the fullest and most expert investigation. This is obviously another matter which ought to come within any scheme of a State Medical Service. To every Coroner's Court there should be appointed a medical officer who should be a specialist in pathological investigation.

ANOTHER instance of the need for **Panel Practice** co-ordination of medical services to **and the** the public is supplied by the pull-**R.A.M.C.** devil-pull-baker relations between the military on the one hand, and, on the other, the insurance officials and the public health officials. A certain number of local sanitary authorities have already refused to allow their medical officers of health to join the R.A.M.C., and many more are likely to follow suit. So far as the Insurance Commissioners are concerned, they are already in a state of great alarm lest the present rally should result in those insured under the Act being left with no one to look after their medical needs. The position is likely to become a serious one, as it is quite evident that a *locum tenens* who has entered into no agreement with the commission cannot be coerced. And a very fair proportion of panel work is now being done by substitutes. The state of mind of the Insurance Commission may be gauged by the tone of a letter addressed to the Worcestershire Committee by Sir Robert Morant in reply to a question.

SIR ROBERT MORANT wrote: "There **An Unworthy** was at present an ample supply of **Suggestion.** doctors to attend to the civil population, but they were unequally distributed. He suggested that before giving consent to any doctor's absence, the committee should satisfy themselves that the remaining doctors would be in a position to meet the demands of the civil population. An assurance of this nature was necessary in order to prevent the doctors offering overwork as an excuse for not fully discharging their obligations under their agreements. Further, any *locum tenens* should be bound to remain either till the doctor returned or the war finished; otherwise, in the event of the deputy joining the Army or leaving for another district, the committee would be placed in a difficult position." That Sir Robert's mind must have been perturbed when he wrote thus is evident from the suggestion, which is quite unworthy of him, that there is a likelihood of doctors pleading overwork as an excuse for not doing their duty. If *locum tenentes* are well advised they will resolutely refuse to bind themselves hand and foot by entering into any contract whatever with Insurance Committees.

I SEE that at a meeting of the **Hinckley Again.** Hinckley Guardians, exception was taken to my observations (Periphery of Jan. 19th) concerning the L.G.B.'s interference to prevent Dr. Murray from obtaining the appointment of M.O.H. because he was of military age. The Hinckley Guardians had a perfect right to appoint anyone whom they thought fit. My criticism was directed, not against them, but against the officials of the L.G.B. who succeeded in "rushing" a matter

with which they had no concern. At the last meeting of the Guardians the Rev. A. E. D. Disney is reported to have said that "he disputed the right of one doctor to sell his practice to another on the promise that the medical officership would go with it." That is exactly the sort of muddle-headed comment, unctuously delivered, which is to be expected from the local parson. Neither I, nor so far as I know anyone else has ever claimed for a purchaser the right to promise his appointments to his successor. There can be no such right, and any purchaser who allowed himself to be beguiled by such a promise would be a singularly confiding fool. What I protested against was the intervention of the L.G.B. to smother such claims as the purchaser in this case might, on his merits, have been in a position to urge.

A Worthy Charity. MISS WHITEHEAD, of 6b, Winchester Road, Hampstead, N.W., is engaged in a very practical charity which makes a special appeal to medical men. News travels slowly to the Hebrides, and publicity is difficult. When war broke out, the fact was announced from the pulpits, and the men immediately rose and left for the mainland. These people are fisher-folk; men, women and girls earn a precarious living from the sea. The men are now employed by the Government as mine sweepers, or what not. The women have their separation allowances; but the poor fisher girls have nothing. Fortunately they can all knit, and they knit socks and stockings of good greasy peat-smelling Shetland wool, which reminds you of Harris tweeds. Miss Whitehead buys these socks and stockings, and pays for them, and she is glad to dispose of them to anyone who wants to send such things to officers or men in the trenches.

Good Value. MISS WHITEHEAD sent me some samples of the work of these fisher girls, and I showed them to an officer home on leave. He was much impressed with them and asked their prices. When I told him that the socks cost 2s. 6d. and the stockings 3s. 6d., he exclaimed that he wished he had seen them on the previous day, for only that morning he had bought several pairs of stockings which were much inferior to these, for which he had paid 6s. 6d. a pair. Being a Scotsman, he felt very much aggrieved that the fates had thus baulked him of a bargain. Medical men very often have an opportunity of recommending articles of clothing for the front, and in connection with the prevention of trench foot they would do well to think of Miss Whitehead and her excellent charity. I understand that Miss Whitehead, of 6b, Winchester Road, has no connection with the Nurse Whitehead who advertises in the Times concerning another charity in which socks have a place.

A Popular Appointment. It is by no means invariably the case that medical appointments to the Royal Household meet with the unqualified approval of the profession. As a rule, indeed, the commissions on these appointments are more frequently

unfavourable than favourable. It is therefore pleasant to be able to record one such against which not a single voice is likely to be raised. Mr. Harold Low, who has recently been appointed anæsthetist to His Majesty's household, is an M.A., M.B., B.C., of Cambridge. He was formerly in general practice in South Kensington, but has for some time past devoted his attention exclusively to anæsthetics and is at present Senior Anæsthetist and Lecturer on Anæsthetics at St. Thomas's Hospital. On grounds neither personal nor professional would it have been possible to make a better selection.

SIR ROBERT PHILIP, who has been moved by some comments in these columns to write a short article which appears in the present issue, is probably the greatest living authority on the subject of which he treats. His views, like those of all pioneers, were at first regarded with deep distrust by the older members of his profession, but although well on the right side of sixty he has lived to see the principles for which he fought become firmly established in all civilised countries. His co-ordinated scheme for fighting tuberculosis has been adopted as a national system. He is the Senior Lecturer on Clinical Medicine in the University of Edinburgh, and Senior Physician to the Royal Infirmary.

SINAPIS.

CURRENT TOPICS.

The Highlands and Islands.

THE Medical Service board of the above has issued its regulations as to medical services at modified fees. We have the same kind of feeling for the term "modified fees" as Lord Rosebery had for "moral victories": it sounds well to the ear and looks indifferently well on paper, but it leaves a bad taste in the mouth, all the same.

The Board has agreed with the practitioners that medical attendance at modified fees shall be made available to the families and dependants of insured persons, uninsured persons of the cottar and crofter classes and their families and dependants, and others in like circumstances to whom the payment of the practitioners' ordinary fee for medical attendance would be an undue burden. The fees chargeable are—not exceeding 5s. for the first visit and 2s 6d. for each subsequent visit in the same illness; midwifery fees (including fees for any subsequent visits that may be necessary) £1. The fees will be the same whatever be the distance of the patient from the doctor's place of residence. What is now the price of horse-flesh, petrol and other things? In the event of any dispute as to whether any patient comes within the scope of the arrangements between the board and the practitioners, the matter shall be decided by the Board. On the face of it the whole thing looks like an abominable piece of sweating. However, as the agreement appears to have been arrived at, it is to be supposed that the doctors are satisfied. They should know their own business better than we do. Yet we venture to think that it would be very ad-

vantageous for any medical man who wishes to practise in that part of Scotland to see to it that he is born a Highlander with a peat-reeky name. Also he should be prepared to live on porridge and do without breeks.

Security of Tenure for Health Officers.

AT last this much needed condition in the appointment of Health Officers has been obtained. The Local Government Board has now prepared an Order giving them security of tenure. Mr. Long wisely thinks it would be inadvisable to issue the Order at the present time for the reason that so many of the men to whom it applies have temporarily relinquished their posts to serve with the forces. Obviously it would be unfair to these patriotic officers if, while they are absent in the service of their country, substitutes were given permanent appointments. It would also be unfair to medical officers on military duties, if posts which became vacant through the death or resignation of the present holders are permanently filled, when men, who in ordinary circumstances might apply for the posts, are precluded from doing so because they are soldiers for the time being. Sir Philip Magnus, who is the Parliamentary champion of the medical officers in this matter, is in agreement with the President of the Local Government Board, with regard to the advisability of postponing the issue of the order until after the war. This is a much needed reform which is long overdue.

Free Medical Assistance for Edinburgh Poor.

WE note that at the 139th meeting in connection with the Royal Public Dispensary of Edinburgh, held on Saturday, a very satisfactory report of the last year's proceedings was laid before the meeting. Less work was done; first, because of the Insurance Act, fewer men applied for relief; and secondly, the medical staff had been reduced by the War's demands from eight to two. It was left to Drs. Cattanach and Darling, with the aid of willing medical students, to carry on the work. This kind of thing is going on all over Scotland. Our ranks are being depleted on behalf of the Army and Navy. Credit to the men who go to the front! What about those who perforce—or even otherwise—stay at home? Exempli gratia: within the sound of the Bells of Trongate lived a practitioner last year whose three medical confreres went out to France, leaving their panels to his honest care. For a month he did their work and his own. But it was too much for him. So he enlisted for a rest. Didn't the late Phil May picture a lion-tamer in the lion's cage, calmly resting while his nagging, angry wife, on what is popularly supposed to be the safe side of the cage, adjures him to "Come out, you coward!"? The analogy is there if you will look for it.

Judges and Justice.

SITTING last week at the West London County Court, during the hearing of a case under the Workmen's Compensation Act, Judge Sir William Selfe is reported to have said: "The matter could easily have been settled for a few pounds, yet we have a medical referee brought here as well as

counsel and several medical men on both sides. It's positively disgraceful."

We do not know the particular circumstances of the case in question, but we have known the learned judge to express similar views in cases where the employer or his representative contended that the workman had recovered from the effects of an accident, and was fit to return to work. It is very often cheaper in such a case to give the workman a few pounds, and pay his solicitor's costs, to avoid proceedings in a County Court, inasmuch as the employer, even if successful in litigation, can hardly expect to recover his costs from the workman. It is obvious, however, and this is in accordance with experience, that if it is to become a custom to hand over moneys to workmen whom the employers' medical advisers consider fit for work, such procedure quickly degenerates into a process of submission to blackmail. Sir William Selje is naturally anxious to expedite the work of his court, but he should not forget that the courts exist for the purpose of doing justice between litigants. For this the judge is paid. No employer, in view of experience since 1906, is anxious for litigation under the Workmen's Compensation Act. If an employer is a party to such proceedings, the judge ought to know that there is good reason for the step. To resist one unjust claim may save many similar claims against the same employer or Insurance Company. In such a case it is money well spent, and it is no part of the duties of Sir William Selje, as a minister of justice, to characterise as "positively disgraceful" proceedings, which he must know are in all probability taken after deliberate consideration by responsible parties.

Eusol.

It would seem that the return to antiseptics caused by the exigencies of military surgery may lead to important advances in our knowledge. We published some weeks ago a preliminary report on the use of urea as an antiseptic, and now we draw attention to hypochlorous acid, which has been the subject of recent investigations by a special committee at Edinburgh. The committee is greatly impressed by the efficiency of eusol, as it is called, as an antiseptic. The cases quoted show a very rapid cleansing even of the most septic wounds. Moreover, in the practice of the surgical outpatient department of the Royal Infirmary, it was found that where eusol was used as a primary dressing 86 per cent. of recent wounds remained aseptic. The strong claim is made that eusol, while efficient, is non-toxic and non-irritating. It is said that, while it is highly destructive to bacteria, it is non-toxic to the tissues. If this be true, we have to do with a drug unique in its properties, as far as our present knowledge goes. At any rate, there can be no doubt that eusol is a useful antiseptic, and it has the great advantage of being inexpensive.

Registration of Nurses.

FOR many years past there has been, as our readers know, a strong agitation among nurses to secure State registration. The official nursing organisations are in favour of registration, but certain of the larger metropolitan hospitals seem to think that their interests are threatened by the proposal, and so far the agitation has not had com-

plete success. A Nurses' Registration Bill has passed the House of Lords on one or two occasions, but up to the present has not become law. Since the beginning of the war nurses have found themselves too busy to spend their time in political activities, and the demand for State registration has been allowed to stand over. Unfortunately, as the *British Journal of Nursing* last week points out, the interests of nurses are now threatened by the proposed establishment of a voluntary scheme of some sort which may "dish" registration. It appears that the Joint Law Committee of the British Red Cross and the St. John Ambulance Societies has taken the matter in hand, and proposes to establish a College of Nursing, one of the functions of which is to grant a certificate of proficiency in nursing. The scheme seems to be sufficiently foolish to condemn itself, but the nurses do well to be on their guard. It is largely owing to the powerful social influence of persons connected with the two societies mentioned that nurses have been deprived of their proper prerogative in attending to our sick and wounded soldiers, and their duties committed to unskilled hands. A committee which cannot distinguish between a nurse with three or four years' training and a voluntary worker with three or four weeks' is certainly not a body to be entrusted with any control over the education of nurses.

After the War.

WE are at present too blinded with the dust of the Titanic conflict to form any just estimate of what lies beyond. The perspective of the human mind is shaken and out of focus; Europe, nay even the world is once again cast into the melting pot. But one thing is certain—that this war is truly a struggle between the Light and the Shadow typified. Upon the one side is the spirit of quest, progress, imagination, spirituality—what you will. Upon the other is that heavy burden, almost inseparable from humanity—System—perhaps beneficent, but also when hypertrophied—a tyrant. The great accepted platitudes of civilisation are in question, Efficiency, Empire, Nationhood, and Wealth. At the conclusion of the struggle all exhausted humanity will clamour for a new scale of values, individualism will be rampant, combated by Socialism, which in itself has recently shown a tendency to systematise also, in an evil and tyrannous sense. The mere clash of physical armies may come to be regarded as less terrible than the uproar of a million human souls searching for reality and a new positive ideal. But out of all, it is our confident hope, will emerge a new era, one step nearer to the realisation of mankind.

PERSONAL.

THE KING has appointed Dr. Harold Low to be Anæsthetist to His Majesty's household.

DR. P. F. MACGREGOR, M.D., Cambridge Park, Wanstead, has been elected Medical Officer of Health for the Wanstead district.

CAPT. J. EWING, late Captain in the 1st West Riding Field Ambulance and Temporary Captain in the Royal Army Medical Corps, is gazetted Captain and a Deputy Assistant Director of Medical Services.

THE Council of the University of Sheffield have appointed Dr. Arthur J. Hall, M.D., F.R.C.P. (Senior Physician, Sheffield Royal Hospital), to the Professorship of Medicine, in succession to Dr. Duncan Burgess.

FRENCH CLINICAL LECTURE

ON

TYPHOID FEVER AND ANTI-TYPHOID VACCINATION.

By L. RIMBAUD,

Médecin aide-major of First Class, Professor at the Faculty of Medicine of Montpellier

[SPECIALLY REPORTED FOR THIS JOURNAL.]

TYPHOID fever manifested itself in the Army with a certain degree of intensity during the whole of the period which ranged from November, 1914, to the April of 1915. Having been attached throughout the whole of that period to an important hospital centre, to which typhoid cases were conveyed for treatment, we have had the opportunity of carrying out, on a very large number of patients, clinical and bacteriological observations which were found to furnish ample material for a large and fertile series of productive studies of the very important questions which arise in connection with this subject.

The circumstances have appeared to us to be quite specially favourable—not exactly for merely determining the efficacy of the prophylactic procedure of anti-typhoid vaccination, which was already fully established and remains the best means of defence against Eberthian infection, but—towards promotion of satisfying research; with the object of determining the limits of the protective results which we may reasonably anticipate from the universal adoption of this procedure, when a sudden and generalised outbreak of typhoid fever appears among troops on active service in the field.

And here it must surely be admitted at the outset that first appearances may prove quite deceptive. Observers who have not previously been duly warned of this fact will have every right to be surprised on seeing an outbreak of typhoid among the troops quickly present a notable range of extension among those bodies of men whom they previously had been led to believe had been effectively safeguarded by protective vaccination. In order to form a sound judgment regarding this very important question it will be absolutely necessary to lay bare the bedrock of our evidential data. This is the task which we have assigned ourselves for scientific and clinical examination on the present occasion.

In order to accomplish this object it was above all things necessary to establish a rigorous bacteriological classification of the whole series of cases which were admitted to hospital with typhoid fever, or with gastric febrile indisposition. This rigorously defined classification could be established only with the aid of the evidence afforded by hæmoculture, which is the sole method of research which enables us to distinguish true typhoid fever, the specific infection due to the presence of Eberth's bacillus, from the essentially distinct clinical entity of paratyphoid. It was against the former disease only that the vaccinated cases had been immunised.

Now, our researches soon came to demonstrate conclusively for us the clinical fact that we were unexpectedly placed in presence of a particularly numerous series of cases of paratyphoid fever—a series of which the items appeared to have assumed a proportionally more rapid and extensive development than that of the cases of typhoid fever proper, as the infective power of the latter disease became more effectively strangled by the more regular and more widely spread employment of prophylactic vaccination. Indeed, the occurrence of paratyphoid fever has been observed by us specially among the

subjects of vaccination. Accordingly the question must here be asked: Can we now definitely assert that the vaccinated have in all cases been permanently protected against the bacillus of Eberth? The answer is: No. And we must also admit our belief that some cases of true typhoid fever have actually occurred among the persons who had received the antityphoid vaccine. But the net result of our collective observations has gone to prove definitely that such cases have been of very rare occurrence—even exceptional—in spite of the very rapid extension of the disease from the very commencement of the epidemic. Besides, it should be always remembered in this connection—and we shall return to the consideration of this aspect of the question after placing before the reader the general results of our researches—that in many of the cases the injection of the vaccine matter had been carried out but irregularly and incompletely; whether it was that the physicians were not duly impressed with the crucial importance of the procedure from the beginning, or—and this was the reason of more frequent occurrence—on account of the difficulties arising from the fact that the vaccinations had to be carried out in the advanced sections of the army in the field; and, in some cases, even on the persons of the soldiers who were actually passing into the firing line, which had to be crossed during the carrying out of the series of antityphoid vaccinations.

In the hospital in which we carried out our researches, the typhoid cases were admitted by hundreds. And no cases were received but those of men who definitely presented the diagnostic features of typhoid or paratyphoid fever; or a febrile indisposition obviously dependent on some gastric source. And, in our own wards, we carry out the procedure of hæmoculture at the very onset in the case of every individual patient admitted. In the other wards, we had recourse to hæmoculture only in the cases of vaccinated subjects and in cases of difficult diagnosis. In this way we had been able to carry out 656 hæmocultures during the period ranging from December 15th, 1914, to April 30th, 1915. The bacteriological researches, and more especially the procedures of identification of the isolated germs, have been carried out in the microbiological laboratory of an army corps, under the direction of M. Russell (médecin-major de 1re Classe), who has thus taken an actively intimate part in this work of research, and to whom we gladly embrace the present opportunity of testifying our liveliest gratitude for his very valuable collaboration.

The technique employed was as follows:—

The procedure of hæmoculture was carried out in a medium of bile (5 to 10 cc. withdrawn through an antiseptic puncture from a vein at the bend of the elbow, added to 10 cc. of ox bile) which was placed in a stove at 37° (68.6° F.). On the following morning it was again sown on bouillon. When the hæmoculture is positive, the bouillon becomes turbid on the same evening. The culture is then unified (mobile bacilli not taking the Gram stain), and now re-inoculated on several different media:

jelly treated with glucose, or neutral red, milk coloured with turmeric, Petruschki's stain, and sugar of lead jelly. The distinctive characteristics displayed by the bacillus of Eberth and the paratyphoid bacilli A and B, respectively, when sown on those media, are indicated in the following table:—

	Bacillus of Eberth.
Jelly with glucose or neutral red.	No modification.
Jelly with sugar of lead.	Darkened.
Milk with turmeric.	Slight permanent acidification
Petruschki's stain.	Do.

the patients themselves. What reliable indications did we secure in that way?

In the first place, we were able to take account of the fact that the very great majority of the men had certainly been vaccinated since the commencement of the war (men of the reserve classes and

	Paratyphoid A.	Paratyphoid B.
No modification.	Darkened.	
Slight permanent acidification.	<i>Caméléonage</i> (temporary acidification followed by alkalinity).	
Do.	Do.	Do.

The identification was then completed by the agglutination of the bacillus after isolation, by means of the specific media (Eberth-serum, Para A-serum, Para B-serum).

The *technique* here indicated does not necessitate the employment of any cumbersome materials (an important practical feature in the case of a bacteriological laboratory for use in the field), and permits the preparation of a response to the inquiry of the clinical physician in charge of the case, after a relatively short interval (36 to 48 hours). *Of the series of 656 hæmocultures thus carried out, 339, or 51.6 per cent., proved to be positive.*

This relatively small percentage of positive hæmocultures depended on the fact that most of the specimens of blood employed had been withdrawn from the respective patients on the eighth to the fifteenth day; they having reached us only after being detained for an interval of observation with the ambulance, and being passed on after the diagnosis of the case had been confirmed. On the other hand, too, a certain number of hæmocultures were carried out for diagnostic purposes in cases of tuberculosis, of pneumonia, etc.

The isolated germs separated out in the following proportional order: Eberth's bacillus, 164; paratyphosus A, 121; paratyphosus B, 54. We do not propose to consider at present any results but those obtained in dealing with the vaccinated cases. The preliminaries were duly carried out in 434 cases of individuals, who had each received from one to four injections of antityphoid vaccine (a). The agent employed in almost all of the cases was the Vincent vaccine; three or four men belonging to the naval corps had received injections of the Chantemesse vaccine; and the Bisredka vaccine was employed in a single case only.

Of the subjects of vaccination, 203 hæmocultures, or 46.7 per cent., yielded positive results. They have presented: Bacillus of Eberth, 51; paratyphosus A, 106; paratyphosus B, 46. Such are the general results obtained by our observations. The above figure, of 51 specimens of the Eberth bacillus isolated from the blood of that number of subjects who had been actually vaccinated against typhoid fever, must appear at first sight rather impressive. But let us proceed to consider the fundamental facts.

At the outset the majority of this series of 51 vaccinated subjects had not received their full number of injections; 4 of the cases had received but one puncture each; 20 two punctures; 17 three punctures; and only 10 had had their four punctures each. The question will now be asked: How did we ascertain those alleged facts? The answer is: From the men themselves. In three-fourths of the cases there was no written entry in the note-book, and we were thus obliged, generally speaking, to content ourselves with the verbal affirmations of

territorials). In some of the cases, the vaccination had been regularly carried out in the depots. A large number of the men had been sent on to the front before the full series of vaccinations had been completed; these had, however, been subsequently carried out in some of the cases; and thus, as a result of unavoidable circumstances, the later vaccinations had been made at irregular intervals—of three weeks or a month, or even more. Under such conditions it may well be surmised that many of the vaccinated subjects had received three or four punctures without actual augmentation of the dose of the vaccine; and that, as a necessary consequence, they had really had conferred upon them merely the mediocre degree of immunity producible by a single injection, in spite of the physical repetition of the puncture several times. And it must also here be added that the vaccinations were possibly carried out in some instances by physicians who had been incompletely trained in the method of procedure; and who did not quite comprehend the importance of the regularity of the repetition of the injections, and the progressive augmentation of the dosage, in securing the subsequent condition of immunisation.

We have already stated that our information was usually derived from the men themselves. The question must then be asked: What definite value should we attach to such information? It must be admitted that some of the patients were at the time of our interrogations in the stage of full development of typhoid fever, often of a grave character; and that, under such conditions, they might well—even without actual desire or intention to deceive—lead us to erroneous conclusions by the defective information supplied through the distorting or cloudy media of lassitude or amnesia. Others, indeed, who were even less gravely affected, were found to be unable to locate times or places in precise fashion; they could not recall the days, or even months, in which they had been punctured, and had actually forgotten the number of injections which they had received. Then a certain proportion, and that a more numerous one than one would be readily disposed to anticipate, actually responded to our queries by giving deliberately false information. The vaguely imaginary dangers of the procedure of antityphoid vaccination had also the effect of frightening a good many of the men, who consequently had recourse to every available means of avoiding it. Men of this way of thinking in some cases made a deliberate pretext of a previous vaccination which had never been carried out, in order to enable them to evade the dreaded ordeal, while others during the course of *séances* to which a large number of effective soldiers had been convoked, were able, without any very great difficulty, to escape the control of supervision, and figure as vaccinated subjects, although they had never received their puncture. In the course of the numerous vaccinations made by us, we have our-

(a) Those injections had all been made at the minimum interval of one month previously; and with a maximum of two months.

selves been able to establish the occurrence of various instances of deception of this variety. And, we should here add, in our cases of vaccinated typhoid patients we have been able to obtain an avowal in some instances, by pressing home the process of interrogation. One young soldier who had typhoid fever of the genuine Eberthian type had at first declared, on being questioned, that he had received four injections of the vaccine. When at the termination of his attack of typhoid fever—and when we had succeeded in obtaining his complete confidence—he revealed to us that he had really received but a single puncture. When they commenced to carry out the practice of immunising vaccination, permission to pass on was given only after receipt of four punctures by each; he had, however, managed to secure his early departure by having himself placed among those whose series of injections had been completed, although he had really received but the first dose. A soldier of a territorial infantry regiment had inscribed the regulation testimony to having received the prescribed number of four antityphoid injections. In the course of his illness (which presented all the distinctive features of paratyphoid A) he confessed to us that the statement contained in the inscription was really inaccurate; having suffered formerly from rheumatic attacks, he was afraid that the vaccination would provoke its crisis anew, and he succeeded in securing the means of escaping the procedure (a).

We could readily cite a number of other instances of the same kind. The reservations thus practised appear to us to be of the greatest importance in considering the subject: explaining, as they unquestionably do, at least in part, the relatively considerable proportion of cases occurring among the vaccinated of genuine typhoid fever characterised by the presence of Eberth's bacillus. In every statistical calculation, we should always take those facts into account; when neglected, they never fail to leave the stamp of error behind. The fact, however, as we are ourselves obliged to admit from the results of our personal experience, is that in the cases of at least four or five of the patients who had been represented as having received their complete doses respectively, the vaccination had actually been completely carried out in orthodox fashion, although the diagnosis of typhoid was confirmed by a positive Eberth hæmoculture. One of them, a hospital official, had been vaccinated by our own hands two months previously. And, if we are to receive as genuine the affirmations of all our patients, ten of the subjects who had received in orthodox fashion the whole series of four injections of Vincent vaccine have subsequently passed through genuine typhoid fever, characterised by the presence of Eberth's bacillus.

We have now to ask ourselves the crucial question: Is there any reason that a doubt should remain regarding the protective efficacy of this admirable method of antityphoid prophylaxis which is furnished by the procedure of preventive vaccination? The researches of Chantemesse and Widal, of Wright, and of Vincent, rest on bases too solid to demand further confirmation. Then,

(a) This article was passing through the press when there appeared in the columns of *La Presse Médicale* (September 30, 1915), an interesting communication from Prof. Vincent, dealing with the subject of "Falsified Vaccination." We have ourselves met with cases—even a great number—of those falsified vaccinations, and our experience in that connection has led us to complete agreement with the very appropriate observations and conclusions of the author. We must also remark here that, our attention having been drawn to the facts by M. Vincent himself, we have, in the course of our own researches, conducted all our inquiries among our vaccinated patients with the greatest possible rigour.

again, after having seen the decisive results obtained from the employment of the Vincent vaccine in Morocco and in France—in the several epidemics of Avignon, of Paimpol, of Puy-l'Eveque, of Montauban—surely no remaining doubt can continue to subsist regarding the prophylactic efficacy of the antityphoid immunisation.

Let us now, in way of final confirmation, cast a generally comprehensive glance over the record of the results obtained. Typhoid fever breaks out abruptly in an army in the field under conditions in which the disease has never been met with since the adoption of prophylactic vaccination. Of foremost importance in this connection has been, of course, our experience of the great epidemic which raged in the Belgian Army. This broke out in the month of November, after the trying days of the battle of the Yser. The troops were then physically exhausted, and a large proportion was formed by territorial regiments. The heavy tribute of the disease was found to be levied, with conspicuous selection, on the men whose ages lay between 35 and 40 years. Vaccination had not been universally resorted to in case of all the effective troops; but it was then proceeded with hastily during the full blaze of the epidemic, and approximately along the firing line. In our special hospital, which was placed in close proximity to the front, we received the patients in hundreds. We retained there only the 656 cases in which we carried out the hæmocultures. Of this total, 434 had been vaccinated; and of these 145 *only must have received their quota of four punctures*; among the cases of this series we discovered the bacillus of Eberth in ten instances. Accordingly we find on summarising the results after making all possible reservations, the vaccinated patients presented true typhoid fever, with the bacillus of Eberth, in only 6.8 per cent. of the total number affected. On the other hand, the non-vaccinated cases of the same epidemic, who numbered 222, furnished us with 113 positive Eberth hæmocultures, or 50.9 per cent. of the series. Then we must here ask ourselves: What therapeutic procedure, either curative or preventive, has hitherto been found to yield absolute results? Do we not meet with cases of small-pox occurring in subjects who have been regularly vaccinated and re-vaccinated; and who can seriously dare to discuss, with the aid of such data, the genuine utility of the Jennerian vaccination?

An actually unquestionable proof of the genuine efficacy of antityphoid vaccination arises, as it seems to us, from the evidence presented by the adjoining table. The statistical summary here concentrated shows at a single glance that the occurrence of genuine typhoid, with the presence of the Eberth bacillus, was rare in direct proportion to the completeness with which the procedure of prophylactic vaccination had been carried out.

	Typhoid states.	Positive Eberth Hæmo-culture.	Per-centage.
Non-vaccinated ...	222	113	50.9
Vaccinated (one injection) ...	21	4	19
Vaccinated (two injections) ...	122	20	16.3
Vaccinated (three injections) ...	146	17	11.6
Vaccinated (four injections) ...	145	10	6.8

We must here specially emphasise the fact that, in the absence of skilled bacteriological research, all those 434 vaccinated subjects would have been labelled cases of true typhoid. What would then have been the resulting estimate of the value of anti-Eberthian vaccination! But, in the light of our present methods of investigation, we have

identified with the aid of hæmoculture 152 cases of paratyphoid fever among 434 vaccinated patients. Thus the blood-culture has demonstrated the presence of the bacillus paratyphosus in 35 per cent. of the vaccinated cases, while the non-vaccinated (to the number of 222) have displayed but 23 examples, amounting to 10.3 per cent. Accordingly, we may now well ask ourselves the question: How could we, before the arrival of an actual epidemic, have been able to suspect the importance of paratyphoid infections?

We are now able to affirm the following facts of clinical statistics: Preventive vaccination has protected us against a serious visitation of typhoid fever; cases have actually occurred among the non-vaccinated, and the irregularly vaccinated; among the vaccinated, in whose cases the procedure had been completely carried out, the occurrence of true typhoid has been extremely rare. And, inasmuch as a relatively large proportion of cases of true Eberthian infection occurred among the vaccinated who had received but two or three doses of the Vincent vaccine, this statistical fact appears to furnish a plea in favour of the necessity for the administration of the full series of four injections.

As the fact now remains that anti-Eberthian vaccination has evidently proved itself to be no defence against paratyphoid infections, it will be suggested by some that the question arises, Whether it does not really seem that they have actually facilitated the extension of the latter form of infection? To this the answer is, that: there are no grounds for the suspicion other than deceptive appearance; in the absence of anti-Eberthian vaccination, such cases would doubtlessly have passed unperceived in the crowded course of a terrible epidemic of typhoid. The features assumed at the outset by the latter were also of a peculiarly grave character; the general adoption of preventive vaccination unquestionably modified the virulence. Paratyphoid fever has continued to evolve. In a forthcoming study we hope to demonstrate the fact that its naturally benign quality renders it a malady infinitely less redoubtable than true typhoid.

ORIGINAL PAPERS.

THE CAMPAIGN AGAINST TUBERCLE.

BY SIR ROBERT W. PHILIP, M.D.,
F.R.C.P., F.R.S.E.

Senior Physician to the Royal Infirmary, Edinburgh;
Lieutenant-Colonel, R.A.M.C.

THE interesting remarks under the above heading in THE MEDICAL PRESS AND CIRCULAR for February 2nd seem to admit of slight amplification. In the campaign against tuberculosis it is desirable to avoid placing in seeming antagonism factors which, far from being antagonistic, are mutually helpful.

The functions of the sanatorium and hospital are sufficiently definite and clear. In so far as they are well equipped and manned, they play an important part in treatment and prevention. They represent a considerable advance on the older line of treatment of tuberculosis. When cases are properly selected, they serve their purpose in a co-ordinated anti-tuberculosis scheme thoroughly well. Both institutions are adjuvant to—and must not be placed in opposition to—other measures in the campaign.

Thirty years ago it was borne in on some of us who were working at tuberculosis that the problem was a wider one than the hospitalisation of tuberculous persons and that the hope of its solution lay in the projection of the search-light into the

home. The recognition of the house as the breeding-ground of tuberculosis—as of much other preventable disease—led to the creation of the Tuberculosis Dispensary. The housing question in the largest sense formed the inspiration of the Tuberculosis Dispensary. The urgency of the question has been emphasised by the facts which the Dispensary has unearthed.

It has been shown, for example, that in 60 per cent. to 70 per cent. of the tuberculosis cases under the care of the Dispensary there existed all the possibility for infection; that is to say, persons living in the given household had been for prolonged periods in closest proximity to one case, at least, of advanced tuberculosis. It has been similarly recorded how in more than 65 per cent. of the cases studied in one centre the tuberculous patient occupied the same bed with one or several persons, and that, in more than 75 per cent. of the cases, the tuberculous patient occupied, if not the same bed, at least the same room. It has again and again been demonstrated that approximately 70 per cent. of the cases occur in dwellings consisting of two rooms only.

The careful investigations undertaken by the Dispensary doctor and nurses at the homes have exposed the hopeless ignorance which, for the most part, exists not only concerning the proper treatment of the tuberculous patient, but also concerning the fundamental principles which are essential to healthy human life.

They have proved up to the hilt that tuberculosis is essentially a house disease and that in crowded centres numerous dwellings exist which are best described as tuberculous nests. They have pointed to the urgent need which exists for the hygienic education of the nation by skilled and sympathetic teachers and the training of fathers and mothers in the physiological principles which govern the rearing of healthy children.

It has been a chief aim of the Tuberculosis Dispensary to carry into the houses and workshops and into the general life of the community the great principles which underlie all sound preventive measures.

Few considerations in the realm of medicine and, indeed, of human experience are more completely satisfactory than the potential which exists for the re-creation of the individual home, and thereby gradually of the community at large, through persistent and well-directed efforts of intelligent doctors and well-trained nurses, who have the *entrée* into the homes where cases of tuberculosis exist. I cannot speak in terms of too great admiration of the work which has been thus effected in my own city through the unremitting labours of a succession of doctors and nurses attached to the Tuberculosis Dispensary. Comparing the present state of matters with what one was familiar with twenty-five years ago, when the work was commencing, the reformation effected in countless homes is very remarkable.

While much remains to be done towards the provision of better houses, with more accommodation and greater sanitary convenience than exists for the most part in the working-class dwelling, there is even more urgent need for a satisfactory diffusion of knowledge how to make the best use of accommodation and resources actually at the disposal of the household. Prolonged investigation has convinced me, as it has convinced the staff with whom I have had the honour of working, that the great difficulty with which we have to contend is the ignorance and helplessness of the average household in respect of air, cleanliness and food.

A great deal of confusion is caused by the mixing of two issues, which ought to be kept separate, namely, the question of an insufficient, truly in-

sanitary dwelling, and the misuse and mismanagement of a house, which itself is sufficiently good.

Most certainly the insanitary house should be ruthlessly condemned. Slum property which is beyond recovery should be closed and removed. It should constitute an offence to offer insanitary dwellings for occupation no less than to expose tainted milk or meat for human consumption. A licence or certificate should be issued by the local authority in the case of every house offered for human habitation, and no house should be occupied which has failed to obtain such a licence. The local authorities have a responsible duty towards those who cannot adequately protect themselves, and they are possessed of far-reaching powers.

This aspect of the matter is always before tuberculosis doctors and nurses worthy of the name. I find, for example, that, during the course of two years, eighty-one houses were specially reported by the medical staff of the Royal Victoria Dispensary, Edinburgh, to the Medical Officer of Health as insanitary, and calling for interference from his side.

On the other hand, if every citizen were placed to-day in a sufficient and sanitary dwelling, the second element of difficulty would remain, namely, the misuse and mismanagement of a house which in itself is sufficient for clean, healthy living. This is a practical question of alarming proportions. Its successful handling entails knowledge, tact, energy and patience on the part of doctors, nurses and visitors. It means the introduction into the ordinary dwelling of the cardinal principles which are the foundation of sanatorium treatment.

The object lesson of the sanatorium must be enforced in the home. The advance against tuberculosis will be in proportion as the cleansing and vitalising properties of fresh air are accepted as *axioms* of domestic life, and the compulsory environment of the developing child is conceived and maintained in obedience to the broad, physiological laws of which the sanatorium is the practical expression.

To have this truth accepted and incorporated in the day-by-day life of the nation should be the goal of the campaign against tuberculosis.

SOME MODERN IDEAS ABOUT ANÆSTHESIA.*

By FRANK L. RICHARDSON, M.D.,
Boston.

THE duties of the anæsthetist have not been strictly defined. To my mind, the anæsthetist is to look after the welfare of the patient during the course of the anæsthesia, and to offer suggestions as to preliminary and post-operative treatment that concerns the anæsthesia. (a) If this definition is roughly accurate, it includes a number of duties besides the actual administration of the anæsthetic.

Not many years ago, it was enough if the anæsthetist got his patient off the table alive, no matter what discomfort the patients had before the actual business of operating, or what happened to them afterwards. Happily for all concerned, those days have passed in all enlightened communities. Not only is the surgeon critical, but the laity, at least in this community, expect certain refinements which not only add to the comfort and safety of the patient, but reflexly add to the reputation of the surgeon. A patient who has had one unfortunate experience will not be very likely to seek more surgical assistance unless he is actually driven to it—in fact, he may influence others from seeking assistance by his tales of suffering. Please do not think that I

believe that all suffering can be prevented by the anæsthetist, but I feel sure that by proper co-operation between the surgeon and the anæsthetist a considerable amount of suffering can be avoided.

Let us begin with the preparation of the patient. The preparation depends to a certain extent on the field of operation, yet there are certain things done as a routine, such as the cleaning out of the intestines, and having the stomach empty.

It is the custom with some operators to give castor oil the night before the operation and an enema the morning of the operation. I believe that this is a most pernicious custom. While castor oil will certainly clean out the intestinal tract, it leaves a very unpleasant condition. Castor oil is an intestinal irritant, and as a result of its use after the violent evacuation, peristaltic movements cease for a varying length of time. If the operation has been on the abdomen this period of intestinal stasis facilitates the accumulation of gas with results that are always painful and sometimes dangerous. Isn't it more rational to give a saline cathartic or Russian oil, followed by a cleansing enema, than to use castor oil? Catharsis should never be too active before an operation because of the debilitating effect, and I believe that it is time well spent to take two days in preparation in cases of chronic constipation or in cases where the intestinal contents must be completely evacuated.

Another matter to be considered is the question of food. Here I realise that I am treading on dangerous ground and that no hard-and-fast rules can be laid down, but there are certain fundamental principles that should be considered.

Where either ether or chloroform is to be the anæsthetic selected, we should try to have the food contain as large an amount of carbo-hydrates and sugars as possible, because it is well known that ether has a tendency to produce a condition of acidosis in patients not having a reserve supply of glycogen in the liver. It is also stated that the degenerative processes in the liver caused by chloroform anæsthesia are largely prevented if the liver has a sufficient supply of glycogen. Particular attention should be paid to this factor in children and debilitated patients. Starvation is above all things the condition that should be prevented, for where there has been a prolonged fasting the glycogen of the liver is rapidly used up. Diabetics form a special group, and I feel strongly that no diabetic should be operated on except in the gravest emergency without a preliminary course of dietetic treatment given by a competent medical man. While it is true that we get away with many operations on diabetics under ether, we are sometimes surprised and alarmed at the symptoms following comparatively trivial operations in other cases.

Around Boston, until within a very short time, we have hardly considered any other anæsthetic than ether. There are several reasons for this. Of all the general anæsthetics, except nitrous oxide, ether is the safest in the hands of the unskilled or moderately skilled. We have, too, a pride in the part Boston has played in the introduction of ether, and this is one of the principal factors that has led to its traditional use here. Ether is not the only anæsthetic to be considered, even if it is the safest in the majority of cases. Nitrous oxide, nitrous oxide and oxygen, chloroform, etc., must at least be considered, and in selected cases one of these is sometimes safer than ether.

I should like just to mention a few indications for the use of some other anæsthetic than ether. No case of tuberculosis of the lungs should be given ether without consideration of some other anæsthetic. The danger is in direct proportion to the

* Read before the Chirurgical Society of Boston.
(a) *Boston Medical Journal*, December 23rd, 1915.

activity of the process and the general condition of the patient. I have quite recently seen two cases of prolonged ether anæsthesia in which the administration of ether lighted up an old and unsuspected tubercular process. Fortunately in these cases the process quickly quieted down, but that was merely an accident. In tuberculosis of recent origin, and especially in active tuberculosis, the patient may recover from the operation only to die from tuberculosis, and the anæsthetist, while he escaped censure, may have been responsible for the unfortunate outcome. Bronchitis is another condition in which one should consider some other anæsthetic.

Since the substitution of novocaine for cocaine in local anæsthesia we have been doing more and more operating with this form of anæsthesia. It has great advantages in many cases. In deciding between local anæsthesia and general anæsthesia there are a number of questions to be considered. Among these are duration of the operation, site of the operation, sepsis, the temperament and general condition of the patient. Local anæsthesia does one thing that must never be overlooked—it does away with the mental and physical discomfort of taking a general anæsthetic. It is true that this discomfort, thanks to more refined methods of giving general anæsthetics, is now much reduced, so that many patients have no physical discomfort and the period of mental discomfort is greatly shortened, yet to some people taking an anæsthetic rather than the operation is the thing to be dreaded. On the other hand, there are many people whose temperament contra-indicates the use of local anæsthesia. They do not wish to be present at their own operation. The proper use of morphine and scopolamine will in many cases do away with this objection, and I wish to urge the more general use of morphine and scopolamine in proper doses as a preliminary to the larger operations under local anæsthesia.

Spinal anæsthesia is another procedure that has a very distinct place. I have rather strong opinions on this subject. Statistically it is much more dangerous than most general anæsthetics or novocaine locally, but in given cases I believe that it is much less dangerous. Especially is it true of operations on the prostate and the more serious operations on the rectum. It is also the anæsthetic of election in diabetics where the field of operation is not too high, and it must be considered in cases with pathological lung conditions.

There is one very considerable advantage that these forms of local anæsthesia have over general inhalation anæsthetics. Of themselves they do not interfere with the taking of regular and sufficient food, which may be of greatest importance.

Nitrous oxide and nitrous oxide-oxygen are anæsthetics that are not properly considered in our selection. Both have been sadly neglected except by those men who have the nitrous oxide-oxygen hobby, and by those few have at times been overdone, so that I think we all share a prejudice against the use of nitrous oxide-oxygen. The truth is we do not know all we should about nitrous oxide-oxygen, and I must confess that I advise its use only in a very limited number of cases. In general, these are cases in which the operator does not require muscular relaxation, and where the operation requires only a short anæsthesia. It now seems crude in most cases for anyone to do a paracentesis of the drum without an anæsthetic or a dilatation and curettage under ether when nitrous oxide-oxygen is available. I mention only these two operations, but of course there are many others where it is an excellent anæsthetic both for the

patient and the operator, and does away with some of the discomfort of most general anæsthetics.

As to the actual giving of the anæsthetics, there are only a few things that need be said. One must remember that all anæsthetics are poisons with the possible exception of nitrous oxide, and therefore the less taken by the patient the better. This being the case a position on the table which gives muscular relaxation, and surgical *technique* which does not require profound anæsthesia are always desirable. It is never wise, however, to hurry the induction of the anæsthesia. One anæsthetic method that I wish to call particular attention to is the method of rebreathing or closed method. Some anæsthetists boast of the small quantity of ether required by this method. It is true that a much smaller amount of ether is added to the inhaler, but it is also true that, where asphyxia plays no part in the maintenance of this anæsthesia, the patient is still getting 15 per cent. by weight of ether vapour, the only difference being that the ether exhaled by the patient is again inhaled with this method instead of being thrown off into air as in the open method. I said "if asphyxia played no part in the anæsthesia," but as the method is usually applied asphyxia does play a part, and a part that is far from desirable. Patients anæsthetised by the closed method are frequently a little off colour, and I believe that they have a greater amount of anæsthetic shock or fatigue. I do not wish it understood that rebreathing has no place in the giving of anæsthetics—this is not true, but when rebreathing is used the oxygen content in the mixture must be maintained as high as in the surrounding air, and we must realise that although the amount of ether added to the inhaler is much less than by the open method, the per cent. inhaled by the patient must be approximately the same. What, then, are the advantages of using this method in any cases? According to Henderson's theory a certain increase in the amount of carbon dioxide inhaled combats the state of shock. While I do not entirely believe in all of Henderson's deductions, it is clinically true that in some cases a condition which we call shock is somewhat relieved by an increase in the amount of carbon dioxide inhaled. We can, however, maintain a proper oxygen content while still increasing the amount of carbon dioxide. This leads to a consideration of the condition of shock. There is probably no more disputed phenomenon in the whole realm of surgery, and when we collect all the real facts about it we have very little to show. Of course, shock is a real condition, but of the mechanism of shock we know very little. Crile's theories, while they are in part true, are not the whole story by a long way. Personally, I think there are two, sometimes distinct, states:—True surgical shock, which is due in part to hæmorrhage and in part to trauma, causing afferent nerve impulses which result in exhaustion of the central nervous system. There is, however, another state resembling shock in which these factors play but little part. This is due to the length of the operation and certain factors in the course of the anæsthesia. I prefer to call this condition fatigue, though whether it differs in kind or only in degree from true surgical shock, I cannot say.

The operating table and the patient's position on the table are other matters about which something should be said. Is there any reason why the operating table should be so uncomfortable? Why not have pads on it thick enough to take off some of the board-like feeling and which will, to a certain extent, prevent the radiation of heat from the patient's body? In most hospitals they put a small pad under the lumbar curve of the spine, so that

when muscular relaxation comes on, this lumbar curve is maintained and there is less strain on the back. Placing a pillow under the knees is of almost as much importance in preventing the post-operative backache, and has the advantage that it promotes relaxation of the abdominal muscles, thus giving the surgeon more room in abdominal work. Let me say one word about the Trendelenburg position. As it is usually carried out, the legs are flexed at the knees. This in itself puts a marked strain on the abdominal muscles, requiring a much deeper anaesthesia to give the required muscular relaxation. It also puts an added strain on the back and is a contributing factor to backache in these cases. I believe that it is very much better to use well-padded shoulder pieces and keep the legs out straight, even at a slight inconvenience to the surgeon. If you have never laid on a table in the Trendelenburg position, with the legs down, I think you will be quite surprised at the amount of muscular tension this position gives. One should avoid whenever possible any position placing the muscles in strain while under an anaesthetic as we do while conscious.

As before stated, the anaesthesia should be as light as possible. Certain unnecessary factors in operative *technique* make it necessary at times to carry the patient along in a deeper stage of anaesthesia than is desirable. Rough handling of wounds and of the abdominal organs makes it necessary to have a much deeper anaesthesia than careful handling would require. While I am strongly in favour of rapid operating, I feel that it is rarely, if ever, necessary to be rough. This rough handling not only requires a deeper anaesthesia, but even when the anaesthesia is deep enough to maintain muscular relaxation the amount of surgical shock is markedly increased. In certain regions and in certain procedures it is particularly desirable to be gentle. Any traction on the intestines or stomach should be particularly gentle. I have seen an abdominal retractor put into a wound and given a jerk in retracting the muscles and peritoneum that caused an immediate spasm of the muscles and an amount of shock that was almost unbelievable. The same thing may occur if a loop of intestines is pulled roughly out through a small wound. In this connection let me commend the self-retaining retractor, which gives retraction without the intermittent pulls and jerks, each one of which acts as a direct stimulus to the contraction of the muscles pulled upon. It is not cutting that causes shock, but pulling and other manipulation. One should be as careful to handle tissues gently under a general anaesthetic as one is under local anaesthesia, if the best results are to be obtained. I have but one word more to say about *technique*. Surgery is done primarily for the benefit of the patient. When the patient is ready to be prepared, the attendants should be ready to do the preparation, and the surgeon should be ready to commence the operation as soon as the patient is deeply enough anaesthetised to allow it.

Post-operative care is another matter for consideration. Fortunately there have been great advances in the last few years, and some of the absurdities of the older post-operative treatment have now become obsolete, such, for instance, as withholding water.

If there is any one time when a patient needs water it is after operation. He needs fluid to make up for loss by bleeding and by perspiration. The fluid taken also dilutes toxic substances absorbed from the intestines so that they are eliminated with less irritation by the kidneys. I believe that there is less nausea and vomiting where water is given. The quantity of fluid may be greater, but the vomiting is of shorter duration and the straining is less.

Whenever vomiting persists acidosis should be suspected and prompt measures for combating this condition should be instituted. It is much better to prevent acidosis by proper diet before operation than to cure it after operation, but in cases where proper diet cannot be given before operation we can usually relieve the condition quite promptly afterwards. Irrigation of the colon with sodium bicarbonate water (3 teaspoonfuls of sodium bicarbonate to 2 quarts of warm water), followed by a nutrient enema of 5 per cent. dextrose solution, will usually relieve the condition quite promptly. Feeding a patient on broths just before and just after operation is one of the absurdities that we shall see entirely disappear within the next few years. They have almost no nutrient value, they throw considerable work upon the kidneys, and they do not greatly relieve hunger. Why should we give them at all. The only possible excuse is that they do not leave any residue in the intestines. Carbohydrates should be given, and when they cannot be given by mouth in sufficiently large doses they should be given by rectum.

Let us again consider the question of backache. Proper position on the table is not always enough to prevent this, and it is well to be sure that the back is not in a position of strain when the patient is returned from the operating room to the bed. A pillow under the knees helps. Frequent changing of the patient's position is also of assistance.

As you see, this paper makes no pretence of being exhaustive. It is intended to call attention to certain neglected procedures and to promote discussion of our present methods, which it is hoped will be for the best interests of our patients.

MENTAL DEFECTIVES: THEIR IMPORTANCE.

By H. VALENTINE WILDMAN, JR., A.B., M.D.,
New York,

Assistant-Surg. U.S. Public Health Service; formerly Assistant-Physician Manhattan State Hospital; Attending Physician Clearing House for Mental Defectives.

WHY of late years have those of the medical profession interested in mental disease been devoting a great deal of their attention to the mental defective of the higher grade? Why has the defective individual been attracting so much notice? Is he a type that fits with the large group of insane, on the one hand, or with the group of idiot on the other? Is he a new type—some outgrowth of conditions under which we live at present; some product of modern civilisation? If he is neither idiot nor insane, why should so much interest be centred upon him? Why should so much time and money be spent devising methods to detect and control him? Why, if a foreigner, should he be denied admission to the country? In other words, what does the term "mental defective" convey? What is he? Wherein does he differ from other mental types? Why is he difficult to detect? Of what social or economic importance can he be that he should be the object of so much attention, country-wide in its extent. (a)

The reason for centering so much attention on these members of society is, that it is now recognised that they are a menace to the race by breeding defective descendants who are most likely illegitimate as well, and that they are one source of enormous expense to the country. These people, while dangerous, either actually or potentially when at large, may be made, under proper supervision, partially if not wholly self-supporting, and can be thereby shielded from bad influences, which, in the

(a) *New York Medical Record*, December 25th, 1915.

nature of their trouble, they cannot resist, and from environments to which they would find it impossible to adapt themselves.

The mental defective is no new type, Cain, of biblical fame, being perhaps of the same stratum. He is, to repeat, no new type except in the sense that pellagra is a new disease in this country. He has always been with us, but the diagnosis has been made only in comparatively recent times, his lack of responsibility has only lately been appreciated. The separation and realisation of the importance of this type—this is new; not the type itself. The moron is ubiquitous and has been so, but his ability to harm has only recently been emphasised.

And now we come to the question of what is he?—this defective or moron as he is called? What are his characteristics? How can he be identified? Is simple inspection sufficient? Must more refined tests be applied? Does age enter into the question? In other words, what is he and how do we detect him?.

Roughly speaking, it is extremely difficult, if not impossible, to make a diagnosis by inspection alone. The individual in question to the superficial view may make a fairly good impression and it is only by close attention to details of physical make-up that the suspicion may be aroused that the subject may be abnormal. These alterations in physical development are the so-called stigmata of degeneration to the importance of which attention has frequently been called especially by Lombroso. They consist essentially in abnormalities in the shape, size, or position of the head, ears, nose, and other features, or in a certain infantile cast of countenance. The suspicion having been aroused must be confirmed or refuted by a mental examination by a competent alienist.

In a given case this usually discloses an individual who is mentally years below his actual age, but not below the seventh year. A person with a mental age below seven is probably an imbecile and so defective that little or no difficulty is offered in his detection, and as he is not as likely to be allowed to run at large, he consequently does not present the menace the more highly developed defective does. The moron is deficient in some socially important trait which depends on some congenital difficulty or mental defect which shows itself in one of three main fields: in the domain of the will, or in the intellect, or in the development of the moral sense. He is particularly defective in the exercise of the powers of judgment and usually shows a marked inability to grasp the meaning or shades of difference of abstract nouns.

Another well-developed characteristic of the higher grade defective is his ability to do a fair amount of work and get along well while under supervision or discipline, with utter failure when this is removed. This trait is particularly in evidence among the class of sailors or rather among a certain percentage of the class of sailors. While under the discipline of the ship they perform their duties quite well, but when relieved from surveillance they are totally unable to care for themselves or their money. Although they may have worked hard for months and suffered more or less hardship yet as soon as disembarked they spend their savings with a lavishness and recklessness that has made the expression "like a drunken sailor" in reference to foolish extravagance, a by-word.

Therefore the reason for and the importance of the detection of this class of mentally abnormal individuals is quite self-evident. Left to themselves, they are an expense and a danger through either their moral lapses or their criminal delinquencies or both. If detected and segregated, they may be able to make their own living or they may not, but

at least they are prevented from propagating a feeble-minded race.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

PRO PUBLICO BONO.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—From time to time in the columns of the Periphery woman has formed the subject of somewhat scathing comment: woman the Pathological, woman the Inefficient, woman the Arrogant, and woman the Sedulous Ape. She has not escaped lightly at the hands of her reviewer, and it is to be doubted whether she has entirely deserved the measure of opprobrium which has been heaped upon her. It is noticeable that she has said little, if anything, in her own defence. Woman is a silent creature. She is also a hard-working one; and those women who at the present moment have something which they must or may do are, as a rule, too occupied in doing it to spend time in defending either themselves or their methods. And it is just because women can do, and in many instances are doing, such excellent work that the measure of real truth in the charges brought against them is so profoundly to be regretted.

In times of stress, such as the present, men ought to feel that they can depend upon the loyal and intelligent co-operation of women. They ought to be able to say: "Here is something that you could do—do it, and help us." That they largely refrain from such a course is, no doubt, partly due to an elemental something in their inherited attitude towards women in general. But the fundamental obstacle lies with woman herself. There are many things done by men which women could also do, if—and it is a great "if"—they would do them in a woman's way. But the woman who does a man's work is not content to do it to the utmost of her feminine ability, considerable though that ability may be. She dissipates her energies in aping the man whom she replaces, his attitudes of mind and body, his speech, his very dress. She becomes, in fine, the human counterpart of that pathetic travesty, the sunflower, who—

"—in the lost endeavour

To live his life, has parted, one by one,

With all a flower's true graces, for the grace
Of being but a foolish mimic sun.

With ray-like florets round a disc-like face."

Now, to assume the fetishes and taboos of a clique to which you do not belong, is assuredly a thing which is not done. Nevertheless there are many women, constitutionally incapable of a grave error of taste in any other direction, who do yet err in this: that they copy the style and manner of an exclusive class—namely, men, to which (being women) they can never belong. Hence they provoke bitter opposition, ridicule and contempt in the quarters where, upon every count, it is most expedient that they should avoid it. If men hate a mannish woman, women despise her.

At the present moment, when our large general hospitals are hopelessly understaffed, the inevitable question arises: Why not relieve pressure by appointing women to the resident posts? The equally inevitable answer seems to be, not that women could not do the work, but that their presence would not be well tolerated. Now, if not,

why not? The need is very great, and there is every probability of its becoming greater. In all communities individual jealousies and antagonisms must arise. But that, merely because she is a woman, the medical resident of a hospital should be unable to "get on" with her matron, sisters and nurses, and at the same time win the co-operation and approval of the visiting staff, is unthinkable. Admitting faults in the attitude of the hospital personnel—and we know how hard a death some preconceived ideas die—the main source of difficulty must, in the end, lie with the woman herself. For limitations, whether masculine or feminine, there is toleration; for artificiality of pose, there is none.

I am, Sir, your truly,
London, N.W. L. F.

DIET AND THE CARE OF CHILDREN'S TEETH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The leading authority, whose identity is not thickly veiled by his initials, has done a service to the medical practitioner by stating in his letter of February 2nd the chief basic facts which govern our knowledge of dental decay. The family doctor is looked upon as a kind of walking encyclopædia of medical knowledge. It must be a help to him when he is provided with true and simple answers to so many of the questions with which he is constantly beset. To the expectant mother who asks what can be done to ensure that her child shall have good teeth he can only reply that no specific treatment towards this end is of any avail. If she desires a healthy, robust baby she must, before all things, attend to her own health. She must remain free from physical and mental overstrain, and by hygiene and dietary promote her strength. She should try to develop a reserve of physical strength which may enable her to provide for her offspring for the proper period a supply of natural food. A mother who can do this is giving her baby a better expectancy of life, as well as the prospect of "a good constitution," including good teeth. As soon as the child is old enough it ought to be taught to chew thoroughly all its food, and ought to be provided with in due course articles of food which call instinctively for mastication. Exercise of the muscles of mastication lead to their development, and that of the bone to which they are attached. The lower jaw, in enlarging, carries with it the arch of the upper maxilla, the teeth of which overlap the lower all round. The first set not less than the second ought to be periodically inspected by a dental surgeon. Much suffering is prevented by filling spots of decay in temporary molars before the sensitive dentine is reached. The first permanent molars appear at the sixth year. They are often mistaken for temporary teeth; but they are to be known by their appearance beyond the first set in the jaw developing backwards. These teeth, for some inexplicable reason, are much more liable to decay than any others of the second set. If attacked, they ought to be filled at once and preserved, until when, between the age of 12 and 14, the second permanent molars are well in place. At this age, when crowding exists, these teeth should be extracted. A crowded set will gradually spread apart, and the space previously occupied by the molars will become gradually obliterated. This measure will in most cases allow of the advance of the wisdom tooth into a useful position, instead of remaining partly buried against the ramus in the lower jaw. To give instruction with regard to the hygiene of the mouth—the maintenance of perfect cleanliness so far as possible—is the function of the dental

surgeon, and this subject is dealt with in books on dental surgery.

I am, Sir, yours truly,
A HOSPITAL DENTIST.

London, W., February 9th.

MONEYLENDERS AND THE MEDICAL PROFESSION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—One of your correspondents a short time ago suggested that although financial subjects do not fall within the province of a medical paper, yet a medical editor, by going a little out of his way, might often save some of his unbusinesslike readers from falling a prey to the sharks which lie in wait for men who have no real knowledge of business. I send enclosed one of three circulars which I have received within the last fortnight from West End moneylenders. It is against these gentry that I ask permission to warn any of your readers who are ingenuous enough to need it. I have good reason to believe that these circulars have been specially sent out to men whose names appear on the *Medical Register*, where my name is also printed, although I have not been in practice for many years. The circular you will see spreads the usual net. Its benevolent author will wait upon clients at any part of the country, and will lend them, probably with no other security than a note of hand, any sum from £5 to £50,000. The *bona fides* of these offers may be judged from the fact that the *Times* has for some years refused to admit moneylenders' advertisements. And I may remark by the way, apropos of the letters on the "Ethics of Journalism" appearing in your journal, that very few of the newspapers have followed the example of the leading paper, although they must know quite as much about the matter. I would like to point out that the Money Lenders Act has proved an entire failure. Once in the hands of these gentry, there is no escape, save through the intervention of a court of law. The appeal to the law involves the exposure publicly of the whole sordid story. The Act is almost entirely in favour of the lender, thanks, as usual, to the inability of our Parliamentary draughtsmen to frame clauses in unequivocal phrases. An attempt to fight a moneylender in a High Court often results in the undeserved disgrace of an innocent victim, who goes away saddled with a bill of costs and fixed firmly in the grip of his merciless enemy. The advice to those about to consult a moneylender is distinctly—Don't. The only safe course in financial trouble is to consult a friend who is a business man, one's solicitor, or one's banker. If money cannot be raised with their advice and assistance, it is better to face with manly courage any alternative rather than to put oneself in hands where ruin is inevitable.

I am, Sir, yours truly,
SENEC.

Manchester,
January 21st, 1916.

BRIGADE-SURGEON LIEUTENANT-COLONEL ANDREW BARRY, I.M.S., of West House, St. Andrews, Fife, left personal estate of £23,066.

DR. JAS. ADAMSON, through ill-health, has resigned the position of medical officer to Hetton Urban District Council, after 20 years' service. He was one of the pioneers of mining ambulance work, and first commenced instructing Durham miners in "first-aid" nearly 40 years ago. In 1870, he introduced the first stretchers used at Hetton in connection with the local collieries, the injured having previously been taken home on carts.

TRANSACTIONS OF SOCIETIES.

THE ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

MEETING HELD THURSDAY, FEBRUARY 3RD, 1916.

DR. M. HANDFIELD-JONES in the Chair.

DR. HERBERT SPENCER and Mr. E. A. BARTON showed a "speculum-camera," a combined Fergusson speculum and camera fixed together by a catch, for taking photographs of tumours and the affections of the cervix and vagina. The instrument measured $8\frac{3}{4}$ inches in length and had a fixed focus with a depth of $\frac{3}{16}$ inch. Illumination was obtained from six electric lamps surrounding the lens. The exposure was 20 to 30 secs. Lantern slides of the photographs taken by the instrument were shown with the epidiascope.

Dr. HERBERT SPENCER showed a wire-fed tubular needle for use in closing vesico-vaginal fistulæ. The needle was a modified and simplified form of Smith's cleft palate needle, which he had used successfully for many years in closing vesico-vaginal fistulæ. In the instrument shown the silver wire was propelled by simply grasping it with the finger and thumb.

Dr. HERBERT SPENCER showed a needle-holder for vaginal hysterectomy and deep pelvic work. The holder was specially designed for vaginal hysterectomy and for ligaturing pedicles in deep and confined spaces. The needle was held by means of a slot at an acute angle with the handles and, owing to the slot not being extended to the end of the jaw, the short "delta" metal needle could be introduced and withdrawn in the same direction by the one instrument.

Remarks by Dr. F. J. McCANN.

Dr. WALTER SALISBURY read a short communication on

THREE CASES OF LABOUR OBSTRUCTED BY OVARIAN CYST.

Case 1. The patient had been in labour six days and the membranes had ruptured two days before her admission to Queen Charlotte's Hospital. The child was dead. A large tense cyst filled up the pouch of Douglas. Dr. T. G. Stevens opened the abdomen and lifted the uterus outside. A dermoid cyst of the left ovary, the size of an ostrich's egg, was withdrawn from the pelvis with some difficulty, being ruptured in the process. The cyst was removed and the uterus replaced in the abdomen. A dead child was delivered with axis-traction forceps *per vias naturales*. The abdominal wound was then closed, and the patient made an uninterrupted recovery.

Case 2. A midwife, finding that the descent of the head was obstructed by a mass which could be felt *per vaginam*, sent for medical aid, but a living child weighing $7\frac{1}{4}$ lbs. was born before the Queen Charlotte's District Medical Officer could arrive. The patient was sent into Queen Charlotte's Hospital, and Dr. J. B. Banister opened the abdomen, removing a semi-solid multilocular cystadenoma of the left ovary weighing $2\frac{1}{2}$ lbs. The cyst had ruptured, and a large quantity of blood and mucoid material was present in the peritoneal cavity. The patient made an uninterrupted recovery.

Case 3. The patient was admitted into Queen Charlotte's Hospital in labour. In the pouch of Douglas there was a hard fixed mass which was diagnosed as an ovarian dermoid. Dr. R. D. Maxwell opened the abdomen. As the pelvic mass was not very accessible, Cæsarean section was performed and a living child delivered. After this the

tumour was removed. The patient made an uninterrupted recovery.

Dr. SALISBURY discussed the different methods of treatment that had been adopted in these cases.

Dr. HERBERT SPENCER said that he was naturally glad to find that the treatment of the first case was considered the best, for this method of treatment had been brought before the Obstetrical Society of London by the speaker eighteen years ago; yet, in spite of his frequent criticisms, many unnecessary Cæsarean sections had in the meantime been performed in such cases. He thought it was time they ceased. With regard to the third case, there would be differences of opinion as to what should be done in labour when the os was not dilated—whether waiting till the os dilated or Cæsarean section should be the line of treatment. There was another treatment which had not been mentioned by the author which was much better than either, namely pushing up the tumour in the Trendelenburg position, which Bossi had shown twenty years ago to be quite easy even when impossible without its aid. The speaker thought the knee-chest position under anæsthesia might be still more efficacious. In any case it should certainly be tried before resorting to Cæsarean section. He had a slight criticism to make on the description of the size of the tumour in this case, which was said to be that of an orange and afterwards this was crossed out and cocoa-nut substituted. It was of some importance in the case of ovarian tumours obstructing labour to know the exact size of the tumours, and, however convenient during clinical examination the likening of the size to that of familiar objects was, tumours removed by operation should have their dimensions accurately given in inches or centimetres.

Dr. R. D. MAXWELL also spoke.

Miss FRANCIS M. HUNLEY, M.D., read a short communication on a case of

FATAL RUPTURE OF THE BLADDER DURING THE PUERPERIUM.

Mrs. W., æt. 26, a primipara, was delivered by forceps for delay in the second stage of labour, December 21st, 1914—right occipito-posterior position of the vertex. The bladder was not catheterised beforehand. The puerperium was uneventful until the ninth day, when, after making a vigorous stretching movement of the right arm, the patient was attacked by violent abdominal pain, collapse and vomiting. Mrs. W. was seen in consultation by Dr. Cuthbert Lockyer the following day and admitted at once to the Samaritan Hospital. The condition by this time was extremely bad, there being well-marked signs of general peritonitis, with free fluid in the abdominal cavity. No urine had been passed since the onset of acute symptoms, thirty hours before. Forty ounces were withdrawn on admission, thirty-four ounces eight hours later. In spite of stimulant treatment the patient's state became gradually worse, resulting in death at 2 p.m. on December 31st. *Post mortem* a condition of general peritonitis was found, due to rupture of a very thin-walled and much distended bladder. The rupture took the form of a horizontal jagged slit at the summit of the fundus of the bladder. There were no local signs of sloughing nor of bruising. The questions arise as to *when* and *why* rupture of the bladder occurred? Miss Hunley thought that there could be little doubt but that it took place when the patient made the stretching movement already described, on the 9th day of the puerperium, because the onset of symptoms was sudden and the patient's state was said to have been satisfactory until then, and suggested the following explanation as to *why* it happened. Forceps were applied to the fœtal

head when the bladder was distended, producing increased pressure on its walls and bruising of its base and of the urethra. This produced atony of the bladder, so that the state of distension was never overcome, the patient only partially emptying the bladder. The sudden movement took place at a time of extra distension, and the strong contraction of the abdominal muscles was sufficient to produce spontaneous rupture.

Dr. AMAND ROUTH asked if it was not possible that the muscle of the bladder was torn during the forceps delivery when the bladder was full, and that the peritoneal covering only yielded immediately previous to the acute symptoms when septic peritonitis so suddenly occurred.

Dr. McCANN asked if a microscopical examination of the bladder wall had been made; for on looking at the specimen the bladder wall seemed to be attenuated at the site of the rupture. From the position of the rupture it was difficult to furnish an explanation of the cause.

Miss HUXLEY replied.

Dr. CUTHBERT LOCKYER read for the President a short communication on

CHORION-EPITHELIOMA FOLLOWING VESICULAR MOLE.

The patient, æt. 49, was delivered of a vesicular mole 20 years previously. In July of last year she expelled another vesicular mole. For three weeks she made good progress, then hæmorrhage recurred. Five and a half weeks after the passage of the mole the President saw her again in consultation, and, finding that the uterus had increased in size, performed hysterectomy. The uterus was found to contain a small mass of chorion-epithelioma which had invaded the muscular wall. The President asked (1) with what degree of frequency does vesicular mole occur more than once in the child-bearing history of any woman? (2) What is the earliest period at which well-marked chorion-epithelioma is found to be present after the expulsion of a vesicular mole? (3) Does this disease perforate the wall of the uterus with any degree of frequency before expulsion of the mole? (4) What constitutes the difference between malignant vesicular mole and benign cystic degeneration of the chorionic villi? He suggested that the resisting power of the uterine wall might be a factor of some importance.

Dr. AMAND ROUTH said that 30 years ago it was thought that if a woman had a vesicular mole she would be likely to have a recurrence if pregnancy again occurred. He had, however, never known of a woman having such a recurrence. He agreed as to the difficulty of detecting the degree of malignancy in chorion-epithelioma, so as to be able to decide in what cases it was justifiable to remove the uterus if the lungs were already attacked, or where it was hopeless to interfere.

Dr. CUTHBERT LOCKYER replied.

INAUGURAL ADDRESS BY THE PRESIDENT.

The PRESIDENT, in delivering his Inaugural Address called the attention of the Section to the need of enlisting the sympathies and activities of general practitioners in the work of the Society. At present the papers and short communications were contributed almost entirely by consulting surgeons and physicians, and the meetings were rarely attended by the men, who working as family doctors, possessed such excellent opportunities of following a case through its entire length, and of watching the effects of varied forms of treatment. He pleaded for the appointment of special clinical committees to carry out a system of collective investigation, and to obtain the assistance of large numbers of general practitioners in bringing forward and tabulating groups of cases. In the course of

his paper he narrated ten cases of double uterus, and demonstrated that this abnormality was not so rare as physicians had usually deemed it to be. The clinical histories of these cases were given in detail, and showed what an important bearing the subject had on diagnosis and treatment. Though only one or two cases might come under the notice of any one practitioner, yet by a combined effort a full and exact knowledge could be built up, and some of the present uncertain and inexact beliefs could be placed on a sound scientific footing. There was much work still needed before we could hold accurate views on the latency of tubercular disease in pregnancy, or again on the comparative advantages and disadvantages of scopolamine in the course of labour; the views of hospital workers and teachers needed to be tested by the experience of general practitioners, and it was only by a carefully planned effort of collective investigation that this result could be obtained.

Dr. AMAND ROUTH congratulated the President on his novel type of presidential address, and thought that his suggestion that a committee should be formed to collect cases of double uterus would prove most valuable.

Dr. HERBERT SPENCER said that he had listened with great interest to the valuable paper on a somewhat rare though very important condition. He had heard also, with great pleasure, the suggestions the President had made as to the need of obtaining the interest and help of general practitioners, who were in a position to make contributions of great value to their proceedings. The need of collective investigation of rare and important conditions was very urgent. As an instance he mentioned the treatment of cancer of the uterus. If all London hospitals interested in this "subject would consent" to report their cases on identical forms, we should have a mass of statistics unequalled by any city in the world. He hoped committees would be appointed to try to bring about such collective investigation.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, DECEMBER 3RD, 1915.

Mr. WILLIAM TAYLOR in the Chair.

A NEW SUBSTANCE FOR PYELOGRAPHY.

MR. A. A. MCCONNELL read a short note on above. He stated that he had asked Professor W. Caldwell, of the Royal College of Surgeons, Ireland, for a substitute for collargol, which would be non-irritating, opaque to the X-rays, and capable of flowing through a fine ureteral catheter. Professor Caldwell had made a preparation of bismuth, which had not been made before, and which had these properties. The provisional name given to the substance was "Skirol." Mr. McConnell showed several radiograms of the renal pelvis injected with skirol, and stated that he had obtained better results with this preparation than with collargol. All the skirol was washed out of the pelvis before any perceptible precipitation took place. Radiograms taken the following day showed no trace in the pelvis. In no case were there any objectionable sequelæ.

NOTES ON TWO CASES OF ANEURYSM DUE TO BULLET WOUNDS.

Mr. C. ARTHUR BALL read notes on above. The first case was that of an officer who was wounded

on April 25th, 1915, at St. Julien. Two pieces of a broken bullet entered his right thigh. After twelve or fourteen days he noticed a pulsation over one of the wounds, but he was told this was only the "femoral pulse." At a medical board on July 10th, 1915, the aneurysm was discovered, although the patient himself thought he was fit for duty.

Operation.—The artery was exposed, and a Crile's clamp applied above and below. The sac was dissected out, and as Mata's operation was not possible, the artery was ligatured above and below the sac. The following morning the foot was warm, no pain was felt, and pulsation was present in the dorsalis pedis artery, so that it seemed likely the collateral circulation had been previously established.

The second case was of an aneurysm of the axillary artery. Private W. was wounded at Loos on September 25th, 1915. The bullet entered just below the outer end of his right clavicle. X-ray examination showed a comminuted fracture of the surgical neck of the humerus. The bullet lay in the thorax. The wound healed in a few days, and the limb was put in plaster of Paris. About three weeks later a pulsating swelling was noticed about the second and third stage of the axillary artery. When the sub-clavian artery was controlled, the swelling diminished to about half its size. The third stage of the sub-clavian artery was ligatured. No alteration in the temperature of the limb was subsequently noticed. A pain which he had referred to the hand immediately became better. The arm and hand rapidly recovered power with the exception of the area supplied by the ulnar nerve, and this was improving. There had been no return of the pulsation at the site of aneurysm, and the swelling had disappeared.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

PATHOLOGICAL MEETING HELD FEBRUARY 4TH, 1916.

The President, DR. LEONARD DOBSON, in the Chair.

THE PRESIDENT showed a specimen and microscopic section of sarcoma of the brain, situated in the posterior part of the left middle frontal convolution. The first symptom in this case was an epileptic fit on December 18th followed by amnesia, aphasia, right hemiplegia, and death on January 23rd. The patient was a man, *æt.* 47.

Dr. J. M. BERNSTEIN showed specimens of (1) syphilitic liver, male, *æt.* 7 months, (2) large aneurysm of thoracic aorta, (3) Hodgkins' disease showing lymphoma of breast, (4) perforation of *œsophagus* from fish bone, death from acute suppurative mediastinitis, (5) polycystic kidney, (6) primary sarcoma of root of lung—secondary growth in liver. Dr. Bernstein also described a case of acute lymphatic leukaemia from which he showed a blood-film.

Dr. ARTHUR SAUNDERS showed (1) a kidney from a case of acute suppurative nephritis affecting one kidney only, child, *æt.* 1, (2) with Mr. Tyrrell Gray a parovarian cyst from a child, *æt.* 2 years (3) with Dr. Reginald Morton, a specimen and skiagram of a large aortic aneurysm.

Major W. McADAM ECCLES showed (1) a microscopic section and skiagrams from a case of mammary tumour associated with a lesion of the tibia, female, *æt.* 34. In this patient the head of the left fibula was found, on examination by Major McAdam Eccles, to be lying outside the external condyle of the femur; the shaft of the left tibia

appeared to be displaced outwards and somewhat upwards although the proximal epiphyseal part of the bone seemed to retain its normal relationship to the condyles of the femur. Examination of the right knee revealed a somewhat similar condition but in a much earlier stage, the fibula being in its normal position, but the tibia having distinct rarefaction. A section of tissue removed from the breast showed typical atrophic scirrhus, while that from the tibia gave no evidence of any neoplasm, primary or secondary, (2) skiagrams of two wedge-shaped dorsal vertebræ, male, *æt.* 28, no signs of any inflammatory mischief nor of any real "crushing."

Mr. H. S. SOUTTAR showed specimens of (1) Elephantiasis of vulva—huge mass excised, patient 8 months pregnant, later, normal confinement, patient *æt.* 35, (2) complete prostatic tumour removed by suprapubic operation, patient *æt.* 70, (3) cystic adenoma of thyroid, female *æt.* 26, (4) scirrhus carcinoma of breast, patient *æt.* 50, (5) carcinoma of stomach, operation—partial gastrectomy and posterior gastro-jejunostomy, male *æt.* 65, (6) large *nævo-lipoma* of face removed by excision. Mr. Souttar said that the patient, a male *æt.* 21, had those other congenital defects, *viz.*, (a) spina bifida occulta over sacrum, (b) gross scoliosis, defective vertebra (1st lumbar), (c) multiple *nævo-lipomata* on back, (d) aortic stenosis, (e) mitral regurgitation, (f) ? patent foramen ovale.

Mr. O. L. ADDISON described a case of aneurysm of the radial artery at the back of the wrist, female, *æt.* 73.

Dr. GEORGE PERNET showed, (1) cultures of favus in various media from the case of a child whose mother had suffered from favus for 30 years, (2) cultures of ringworm, (3) cultures of streptothrix to compare with megalosporon ringworm.

Major J. M. ATKINSON showed several skiagrams of injuries to bones due to shrapnel.

Mr. H. TYRRELL GRAY showed the following skiagrams, (1) congenital scoliosis, half lumbar vertebra only, (2) congenital absence of half the 8th and 11th dorsal vertebræ, thirteen ribs on one side and twelve ribs on the opposite side—congenital scoliosis, (3) congenital scoliosis, defective development of half the 5th dorsal vertebra, (4) spina bifida occulta, 4th lumbar vertebra, (5) congenital club-hand, (6) unusual type of tuberculous hip disease, (7) scoliosis in a boy due to shortening of one leg of which the bones show a condition resembling fibrocystic disease, (8) tuberculous arthritis of ankle joint.

Dr. REGINALD MORTON showed the following skiagrams, (1) large aneurysm of arch of aorta, male, *æt.* 41, to illustrate radiographically Dr. Bernstein's specimen, (2) branched calculus in the pelvis of the right kidney, female, *æt.* 37, under care of Mr. H. S. Souttar, (3) showing absorption of bodies of the 4th and 5th lumbar vertebræ following an attack of paratyphoid—for comparison with Major W. McAdam Eccles' skiagram showing wedge-shaped vertebræ, male, *æt.* 30, under the care of Dr. Arthur Saunders, (4) wrist showing changes in bones and joint spaces due to sepsis, male, *æt.* 28, (5) osteoarthritis of left hip, male, *æt.* 43, under care of Mr. Tyrrell Gray, (6) rarefying osteitis of upper end of tibia and fibula, female, *æt.* 37, under care of Mr. O. L. Addison, (7) Pathological dislocation of right hip from tuberculous disease, male, *æt.* 10, under care of Mr. O. L. Addison, (8) skiagram showing early tuberculous invasion of lungs, striæ and mottling being close in around the hilum—the periphery of the lungs being clear—the detail in this skiagram was extremely fine, and this exhibit gave rise to an interesting discussion in which the President, Dr. Arthur Saunders, Mr. O. L. Addison, Dr. Reginald

Morton, and other members took part, on the value of radiography as a means of detecting pulmonary tuberculosis in its earliest stages, before physical signs make themselves apparent.

The PRESIDENT, Major W. McADAM ECCLES, Mr. O. L. ADDISON, Mr. H. TYRRELL GRAY, Dr. ARTHUR SAUNDERS, Dr. PERCY POTTER, Mr. RICKARD LLOYD, Dr. J. M. BERNSTEIN, Dr. REGINALD MORTON, and others discussed the various specimens and skiagrams shown at the meeting.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD JANUARY 21ST, 1916.

The President, DR. WILLETT, in the Chair.

OWING to the continuance of the war, it was resolved:—

(1) That the present officers be re-elected for the year 1916.

(2) That no meeting of the Society be held until the annual meeting in January, 1917, unless the course of events altered and made it desirable to hold one in October.

(3) That the annual subscriptions be not collected while the Society discontinues its meetings.

Mr. CARLTON OLDFIELD (Leeds) exhibited a specimen of

RETAINED MENSES IN ONE HALF OF A DOUBLE UTERUS

The patient had severe abdominal pain, suggestive of appendicitis, and it was only when the abdomen was opened it was discovered that the uterus was double, and one side much distended with retained menses owing to an absence of an os on that side. The vagina did not possess a septum.

Dr. W. E. FOTHERGILL (Manchester) opened a discussion on the "Notification of the so-called Puerperal Fever." It was pointed out that though Semmelweis showed before 1850 that there was no such infectious disease as "puerperal fever," the continued use of the term in the registration of deaths and under the Notification of Infectious Diseases Act had kept up the idea that such a disease existed. But though births, deaths and marriages might be counted, it was no more possible to enumerate cases of puerperal pelvic infection than it was to enumerate cases of wound infection in general. The official figures for 1912, for example, showed that in Liverpool 78 per cent. of cases notified as puerperal fever were fatal, while in Manchester only 16.3 per cent. of the cases notified as puerperal fever died. Such a discrepancy was enough to show that the notification of so-called puerperal fever is a farce. It had never done any good, for the reduction of the late years in the mortality from puerperal fever was due to the education of doctors, midwives and the public in clean midwifery, just as the reduction of deaths from wound infection was due to clean surgery and not to notification.

The paper was discussed by Drs. SCOTT, DONALD, OLDFIELD, SHAW, GRIMSDALE, and the PRESIDENT.

DOLLIS HILL HOUSE, Willesden, where Gladstone stayed frequently when Prime Minister, has been opened as a military hospital.

MR. WILLIAM FARRER ECROYD, of Credenhill Court, near Hereford, and Whitbarrow Lodge, Westmoreland, lord of the manor of Credenhill, M.P. (Conservative) Preston 1881-5, left £500 to the Victoria Hospital for Burnley, £250 to the Hereford General Hospital, and £100 each to the British Hospital and Home for Incurables and Cancer Hospital, Brompton.

OBITUARY.

DEPUTY INSPECTOR-GENERAL TRIMBLE, L.R.C.S.I.

DEPUTY INSPECTOR-GENERAL JAMES TRIMBLE, late of the Royal Navy, has died at Merstham, Surrey, in his 79th year. Qualifying L.R.C.S.I. in 1858, he joined the Naval Service, and was employed during the naval and military operations in the Eastern Sudan in 1884, obtaining mention in despatches and receiving the medal and the Khedive's bronze star. He retired in 1893 as a Deputy Inspector-General of Hospitals and Fleets.

SURGEON LIEUT.-COL. A. J. BELEMORE, M.R.C.S., L.S.A.

SURGEON LIEUT.-COL. ALFRED JOHN BELEMORE has died at Brighton in his 77th year. He qualified M.R.C.S. and L.S.A. in 1861, and in the following year entered the Army Medical Service as a Surgeon to the Royal Artillery. He had been on the retired list since 1883.

DR. F. T. B. LOGAN, L.R.C.P. AND S.ED., M.R.C.S.ENG., BRISTOL.

THE death of Dr. F. T. B. Logan, of Eastfield, Southville, Bristol, occurred suddenly on February 7th. During the day he had attended his patients as usual, and in the evening he was taken ill and died in a few hours. Dr. Logan, who was in his 58th year, was born at Kettering, in Northamptonshire, and was educated at the Bristol Grammar School. Upon leaving, he joined the Bristol Medical School, and attended the General Hospital, where he won the Lady Haberfield Scholarship, the Clarke Surgical Scholarship, and the Lady Haberfield Pathological Prize. Subsequently he went to Guy's Hospital, London. He took the degrees of M.R.C.S.Eng. (1879), L.R.C.P.Edin. (1880), and L.M.Edin. Upon qualifying, he settled down to practise in Bedminster, and continued to reside in the district up to his death. For 14 years he was Medical Officer of the Bristol Sanitary Fever Hospital. He was Surgeon to the Post Office, and was actively concerned in the administration of the National Insurance Act. Upon the outbreak of war he threw himself with characteristic energy into the heavy work which has fallen upon the profession, both in the matter of the examination of recruits and the cure and treatment of the wounded. It may be mentioned that he lost his eldest son when serving as a volunteer in the South African War, and that both his remaining sons joined the Army (in which they hold commissions) soon after the present war broke out.

REVIEWS OF BOOKS.

BANDAGING. (a)

THIS small work appears at a time when nearly everybody is trying his or her hand at the art of bandaging. To all of those who wish to make themselves expert at this branch of surgery we can thoroughly recommend Captain Fitzwilliams' book as a practical, clearly written, and helpful work.

In the first part he adequately describes the method of application of the roller bandage to the various parts of the body. The uses of the triangular or military bandage are ably and clearly dealt with. There is also much useful information about special bandages and plaster strapping. We regret that the author has omitted a description of the "St. John arm sling" in this otherwise comprehensive little work. We are indebted to the pencil of a Hungarian prisoner of war for the illustrations, which show a refreshing change from the usual drawings of our text books. The frontispiece—a figure of the

(a) "A Practical Manual of Bandaging." By Duncan C. L. Fitzwilliams, Captain, R.A.M.C. (T.). Demy 8vo. Pp. viii. and 92. One plate, 140 figures in text. London: Baillière, Tindall and Cox. 1915. Price 3s. 6d.

German Crown Prince with his foot in a sling—is particularly entertaining, especially when we remember the nationality of the artist. We feel sure that this book will prove helpful not only to beginners, but also to those of us who have grown somewhat rusty in the art of bandaging.

ST. BARTHOLOMEW'S HOSPITAL. (a)

FOUNDED by Rahere in 1137, for nearly eight hundred years St. Bartholomew's Hospital has ministered to the wants of the sick and wounded of the City of London. The hospital has become part and parcel of that great city, sharing in its benefits and ministering to its wants in troublous times, and after the long life of eight hundred years is, if possible, more vigorous than ever. Like a true *alma mater*, "Bart's" seems to inspire her children with a warm affection for her, but never, we believe, has she had a son who was more intimately acquainted with her history than Norman Moore. In his Rede Lecture he gives us a glimpse at the doings of St. Bartholomew's in peace time and in war time throughout her long history, and shows us how she is at present worthily maintaining her ancient tradition. We accept this lecture gratefully, but we hope that Dr. Moore does not think that we shall be satisfied with it as a substitute for his long-promised history of the hospital.

MEDICAL NEWS IN BRIEF.

Royal Medical Benevolent Fund.

THE annual general meeting of the members of the Royal Medical Benevolent Fund was held at 11 Chandos Street, Cavendish Square, Sir John Tweedie presiding. The book value of the securities was reported to be very nearly £100,000. This yielded £3,600 per annum, which was devoted to the support of the annuitants. Miss Jenkins-Brown was appointed an additional member of the Committee. On the motion of Sir William Church, Sir John Tweedie was re-elected President. Dr. Samuel West was re-appointed Hon. Treasurer, and Dr. C. Newton Pitt Hon. Secretary.

Harveian Society of London.

A MEETING of this Society will be held on Thursday, Feb. 24th, at the Stafford Rooms, Titchborne Street, Edgware Road, at 8.30 p.m., when a discussion will take place on the "Treatment of Gunshot Wounds," to be opened by Sir Berkeley Moynihan, and continued by Mr. D'Arcy Power, Mr. Burghard, Mr. Percy Sargent, Mr. Clayton-Greene, Dr. Fleming, and others. The meeting promises to be a very interesting one, and the President and Council cordially invite all members of the profession to be present, who may be desirous of hearing the discussion.

Glasgow Royal Infirmary.

THE report of the managers of the Glasgow Royal Infirmary draws attention to the fact that the capital fund has for the second year in succession been seriously encroached upon to meet, along with the combined ordinary and extraordinary revenue, the year's expenditure. The maintenance and administration charges amount to over £5,000 per month, while the ordinary income amounts to little more than one-half of that sum. Even after applying the sum of £13,070 9s. 11d. (the net amount received during the year by way of legacies, donations, etc.), it has been necessary to withdraw the sum of £15,428 18s. 10d. from capital account. The position, it is pointed out, is becoming sufficiently alarming to call for speedy remedy. The capital funds of the infirmary, already greatly reduced by the contribution to reconstruction expenditure, are being further depleted instead of being, as was hoped, increased.

(a) "St. Bartholomew's in Peace and War." The Rede Lecture, 1915. By Norman Moore, M.D., Consulting Physician to St. Bartholomew's Hospital. 8vo, pp. 56. Cambridge: At the University Press, 1915.

and the very life of the institution as a voluntary hospital is now threatened. The managers therefore earnestly appeal for a further and largely increased financial support to the extent of at least an additional £30,000 per annum. The ordinary expenditure of £61,750 6s. 10d. was £3,704 9s. 9d. in excess of the previous year. This is accounted for by the larger number of indoor patients treated and the higher cost of provisions, coal, drugs, etc. The managers continued during the year to place at the disposal of the naval and military authorities 150 beds for sick and wounded sailors and soldiers, and these have been more or less continuously occupied during the year without interfering with the ordinary work of the institution. Practically all the members of the medical and surgical staff have been doing military duty. Thirty-eight hold commissions in the Royal Army Medical Corps and twelve are engaged in Red Cross hospitals.

The Royal Sanitary Institute.

ON March 9th, at 4.15 p.m., at 90 Buckingham Palace Road, a discussion will take place on "Food Inspection, Standards of Purity for Food Supply in War Time, and the Utilisation of Condemned Stores," to be opened by J. Wright Mason, M.B., D.P.H., Medical Officer of Health, Hull. The chair will be taken by Sir William J. Collins, K.C.V.O., D.L., J.P., M.D., M.S., Vice-President. The following will take part in the discussion:—R. King Brown, M.D., D.P.H., M.O.H., Bermondsey; W. J. Howarth, M.D., D.P.H., M.O.H., City of London; H. R. Kenwood, M.B., D.P.H., M.O.H., Beds. C.C. and Stoke Newington; W. Perrin Norris, M.D., D.P.H., Chief Medical Officer, Australian Commonwealth Medical Bureau; Samuel Rideal, D.Sc., F.I.C., J.P.

Royal Society of Medicine—Section of Odontology.

A DEBATE on "War Injuries of the Jaws" will be held on Monday, February 28th, at 5.30 p.m. An exhibition of dental splints, models, radiograms, photographs, and other apparatus illustrating the same subject will be open from Tuesday, February 22nd, to Monday, February 28th. Anyone wishing to exhibit is asked to send in full particulars addressed to the Hon. Secretary, Section of Odontology, Royal Society of Medicine, 1 Wimpole Street, W., who will return them to their owners immediately after the close of the exhibition.

Royal Medical General Fund Guild.

THE annual general meeting of the Guild will be held at the Mansion House on Monday, February 21st, at 3.30 o'clock. The Right Hon. the Lord Mayor will preside. The speakers will include the following:—Adeline, Duchess of Bedford, Mrs. Scharlieb, M.D., M.S., Dr. Louisa Garrett-Anderson, Sir Arthur May, K.C.B., Sir John Tweedy, LL.D., James Campbell McClure, Esq., M.D.

Irish Medical Schools' and Graduates' Association.

WE are informed by Dr. Shepherd Boyd, of Harrogate, Prov. Hon. Secretary, Irish Medical Schools' and Graduates' Association, that the final selection for the Arnott Medal took place last week in London. The Council had the greatest difficulty in making the selection from so many brave candidates, but after deliberate consideration the medal was awarded to Captain W. M. Loughman, R.A.M.C., R.C.S.I.

Birmingham Hospital Unit for the Front.

LIEUT.-COL. GILBERT BARLING has been authorised by the War Office to raise in the Birmingham district a medical staff for a hospital unit of 1,040 beds for service abroad, probably in the East. The hospital is urgently needed, and a staff of thirty doctors, excluding the commanding officer and quartermaster, are required, and practically the full number has been secured. The Committee of the General Hospital have given permission to three members of their staff to join the unit, and most of the other doctors are in practice in Birmingham. A few of the members of

the new hospital staff are drawn from outside the immediate Birmingham area, but nearly all of these have either been educated at the Medical School in Birmingham or have formerly held appointments in the city, and for that reason were anxious to join. Had circumstances permitted, Lieut.-Col. Barling would probably have accompanied the unit, but his other duties in the city, and particularly his position as Vice-Chancellor of the University, which is surrounded by many difficulties at the present time, have prevented him from going abroad. It is understood that a commanding officer will be appointed from the regular R.A.M.C. The new hospital is purely a Government service unit, and does not involve any local financial responsibility.

Medical Scholarships.

FOURTEEN medical entrance scholarships and exhibitions, of an aggregate value of about £1,200, tenable in the Faculties of Medical Science of University College and King's College, and in the Medical Schools of Westminster Hospital, King's College Hospital, University College Hospital, and the London (Royal Free Hospital) School of Medicine for Women, will be offered for competition on Tuesday, July 18th, 1916. Particulars and entry forms may be obtained from the Secretary of the Board, Mr. J. F. Hales, M.A., King's College, Strand, W.C.

The Morphine Habit.

WITH a view to checking the habit of laudanum drinking, the Council of the Pharmaceutical Society has passed a resolution to the effect that all preparations of opium containing 0.75 per cent. of morphine (roughly $3\frac{1}{2}$ gr. in the ounce) should be added to Part I. of the Poison Schedule. Hitherto the sale of preparations containing less than 1 per cent. of morphine has only been subject to minor restrictions, and old-fashioned laudanum, for which there is still a demand among opium *habitues*, escaped the more stringent regulations. It will now be illegal for chemists to sell it to any person who is not personally known or introduced to them, and the buyer will have to sign the poison book.

Tuberculosis at Wednesbury.

At the quarterly meeting of the Wednesbury Town Council on February 7th, the Medical Officer of Health referred in his report to the very marked prevalence of tuberculosis, to which no less than 20 per cent. of the mortality was attributable. This constituted a most regrettable state of things, especially when it was observed that the incidence of deaths was mainly amongst persons below middle age, and therefore at the period of greatest activity and usefulness. Such figures afforded little support to the claims advanced on behalf of the more recent method of treatment, or, at any rate, suggested that the cases for the most part did not come under thorough treatment in the early stages.

Dundee Municipal Sanatorium Opened.

ASHLUDIE SANATORIUM, Monifeth, was formally opened on February 9th. The sanatorium, which is part of Dundee Town Council's scheme for the treatment of tuberculosis, has cost about £24,000, of which sum the Treasury will bear a considerable part, and affords accommodation for 64 incipient cases of the disease.

Protection from X-rays.

At the meeting of the Röntgen Society on February 1st a discussion took place on the subject of protective devices for X-ray operators. Dr. Sidney Russ pointed out that although X-ray dangers were becoming less formidable, owing to the more general knowledge of the peril, yet at the same time the neglect of precautions was all the more serious on account of the increasing power of X-ray outfits. The X-ray outfit of the most modern type was capable of fifty times greater power than the ordinary outfit of ten years ago. He thought that X-ray workers would prefer not to invoke legislation on this subject if

sufficient protection could be obtained by other means, for of all the methods available for ensuring it, legislation would be the least popular and the least convenient. He and other speakers suggested that certificates of safety should be given with X-ray apparatus.

Abilities and Character of Doctors.

At a meeting of the Staffordshire Insurance Committee on February 5th, attention was called to a recommendation appointing two doctors to the panel list, and inquiry was made if any means were taken to ascertain the abilities and character of these men.

The Clerk said if a doctor was on the Medical Register he was entitled to go on the panel.

Replying to Dr. Shufflebotham, as to one of the doctors mentioned, the Clerk said he was already on the panel, and the reason for a fresh application was that he had gone to another district, and a new contract had been made.

It was moved that the name in question should be referred back for further consideration, but the Chairman declined to accept it because of the ruling given by the Clerk.

Austria's Need for Army Doctors.

THE Austrian War Office has just ordered all doctors, whether specialists or not, who are physically fit for service at the front, to be enrolled as army doctors. The only medical men allowed to undertake civilian practice are those who are physically unfit for service at the front. Apparently thousands of sick and wounded fail to receive proper attention owing to the scarcity of medical men. The hospitals are complaining that they cannot procure numerous requisites, particularly indiarubber gloves.

Medical Officer's—Appointment by Guardians against L.G.B. View.

NOTWITHSTANDING an intimation that the Local Government Board's view is that such vacancies should not be permanently filled, the Stockport Board of Guardians, on February 7th, decided to appoint Dr. J. Howie Smith as Medical Officer of the Workhouse and Stepping Hill Hospital, in succession to the late Dr. Barker Bale.

Mr. Sharples, who had given notice to move the appointment of Dr. Smith, who has acted as deputy for 15 years, declined to withdraw his motion, and said it was in the best interest of the nation that the appointment should be made now.

It was argued by several speakers that the medical men serving with the forces were not being given a chance of the appointment.

An amendment to postpone the appointment during the war was defeated, and the resolution was carried by 18 votes to 12.

Health of Hampstead.

IN his report to the Hampstead Borough Council on February 3rd, Dr. F. E. Scrase, the Medical Officer of Health, stated that during the six weeks ended January 8th, 97 births were registered in the borough. The birth-rate was 9.7 per 1,000 per annum of the population, as compared with the rate of 13.1 per 1,000 of the population during the corresponding period of last year. 135 deaths were registered, of which 49 were of non-resident persons. The deaths of 25 Hampstead residents which took place outside the borough were also registered during this period, the total deaths belonging to Hampstead being 111. The death-rate was 11.1 per 1,000 per annum of the population, as compared with a rate of 12.0 per 1,000 of the population during the corresponding period of last year.

London Fever Hospital.

A SUCCESSFUL year's work, under rather stringent financial conditions, was presented in the report of the London Fever Hospital at the annual meeting held on February 10th, under the presidency of Lord

Balfour of Burleigh. Mr. Muir Mackenzie mentioned that there was a deficit on the year of rather over £1,000. Considering, however, the diminished receipts, increased wages, and the extortionate prices of some drugs, there was reason for congratulation that the deficit was not larger. Legacies dropped to £200, as compared with nearly £2,000 in the previous year.

The annual report, presented by Captain Box, M.D., stated that the chief feature of the cases treated was the notable increase in measles and German measles.

Dr. Sidney Phillips remarked on the change in diseases mentioned now as compared with the records years ago. Since he was connected with the hospital typhus had disappeared from the records, while cerebro-spinal fever had taken its place, and quite recently Nigerian fever had been diagnosed. The number of cases of German measles had arisen from the aggregation of large numbers of recruits in camps. There had been a good deal of discussion as to whether the disease should continue to be called German measles, but a change in name would not reduce liability to infection.

Lord Balfour of Burleigh said that the number of patients treated in the hospital last year was 1,059, a larger number than in any year since 1882. One reason was that the hospital was taken advantage of by people who did not wish to go to an ordinary hospital and "sponge" upon the public, but who could not afford to go to a nursing home. That was the direction in which the hospital was doing the greatest public service. They had treated, not only soldiers in training for the front, but several who had returned wounded and were suffering from infectious diseases. Last year there had been a falling off of £117 in subscriptions. It was not very large in relation to the whole, but he thought an institution like this should be one of the last to suffer when expenses were cut down. The new wing which had been built would tend to the efficiency of the hospital, and the fact that they had had this extra expense gave an additional plea for kindly consideration by those who were making large war profits.

London Ambulance Stations.

In connection with the London County Council, ambulance service stations have been established as follows:—A, Fulham, 239, North End Road, W.; B, Bloomsbury, 15, Herbrand Street, Tavistock Place, W.C.; C, Shoreditch, 5, Montclare Street, Bethnal Green, E.; D, Lee, 142, High Road, Lee, S.E.; E, Brixton, 5, Buckner Road, Brixton Hill, S.W.; and F, Elephant and Castle, 15 St. George's Market, London Road, S.E.

British Hospital for Corfu.

With a large part of the Serbian army now established at Corfu, the question of hospital accommodation has become one for serious consideration. The Chairman of the Serbian Relief Fund has received a cable from Corfu informing him that the French and Serbian authorities there would welcome the establishment of a British hospital. Accordingly arrangements have already been made by the Serbian Relief Fund to despatch such a hospital (the seventh hospital organised by the Serbian Relief Fund) to Corfu, and Mr. E. P. Warren, F.S.I., F.R.I.B.A. (a brother of the President of Magdalen), has been appointed administrator.

MEDICAL WAR ITEMS.

THE death in action has been announced of Capt. Seymour Stritch, 6th Battalion Connaught Rangers, who before the war was a medical practitioner in Dublin. Dr. Stritch was a native of Dublin, and obtained the conjoint qualifications of Scotland in 1895. Having spent some time in asylum work in Scotland, he settled in Dublin. He was for a time Governor of the Apothecaries' Hall of Ireland, and he was a magistrate for the county borough of Dublin. During the struggles arising out of the National

Insurance Act he took a line different from that of the great bulk of the profession, and as a consequence many professional friendships were broken. Now that these struggles are at an end many of his old friends looked forward to renew these ties, but it has been ordered otherwise. When the war broke out he accepted a commission in the Durham Light Infantry, from which regiment he afterwards transferred to the Connaught Rangers. His death occurred in action in Flanders on February 7th.

Lieutenant Francis Gethin Hopkins, M.D., Royal Army Medical Corps, who has died at Plymouth, was formerly Principal Medical Officer of the Gold Coast Colony. He was a B.A., Dublin, and an M.D., 1903, and he had held professional appointments at the Liverpool Infirmary and the Liverpool City Fever Hospital. Lieutenant Hopkins, who was gazetted temporary lieutenant in the R.A.M.C. in September of last year, was the son of the late the Rev. John Wright Hopkins, Aherm Vicarage, Fermoy, Cork.

Lieut. George Dewar, M.B., Royal Army Medical Corps, killed in France, was the second son of the late Mr. David Dewar, of Aberdeen. While serving as a corporal at Bedford he obtained permission to return home to complete his medical course at Aberdeen University. After graduating with distinction he obtained a commission, and was almost immediately sent to the front. At Aberdeen University Lieut. Dewar, who was 23 years of age, won much distinction in athletics, being a good Rugby footballer and cricketer.

Lieut.-Col. William Moyle O'Connor, M.D., 6th London Field Ambulance, Royal Army Medical Corps, who has died on service, always took a keen interest in the medical work of the Services. He was formerly a major in the R.A.M.C., and he was gazetted an honorary major in the Army in April, 1903, while in March, 1913, he took up his commission as lieutenant-colonel of the 6th London Field Ambulance. He received his medical education at University College, King's College, London, and Trinity College, Dublin. He graduated an M.B., B.Ch.Dub., 1887, and M.A., M.D., 1897. Amongst the appointments held by him were those of Examiner and Lecturer to the St. John Ambulance Association and Medical Officer to the Actors' Association. He was also on the staff of Meath Hospital and Physician to the Aldershot Hospital. Among his works was "The Army Medical Reserve Difficulty," which appeared in 1905. Col. O'Connor was was of the military members of the Territorial Force Association of London.

Lieut.-Col. John Wilfred Stokes, R.A.M.C. (T.R.), 3rd West Riding Field Ambulance, has died at Latchmere, Ham, as the result of shell-shock in France. He was the eldest son of the Rev. Arthur and Mrs. Stokes, formerly of Musoorie, U.P., India, and was 43 years of age.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

REPLY. CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s. post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our official appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer not necessarily for publication, but as evidence of identity.

THE WEST COUNTRY SCORES.

In 1915, of towns with population over 200,000, Bristol and Plymouth were the most sober.

EMBERTO (Leeds).—We have considered our correspondent's suggestion, but regret to say that, at the present time, a favourable reply is impossible.

A COUNTRY PRACTITIONER.—Application should be made direct to the War Office, and the question submitted to the Director-General of the Army Medical Service.

TEESDALE GUARDIANS AND VACCINATION.

REPORTS presented at a meeting of the Teesdale Guardians at Barnard Castle showed that a large number of children in the district were not vaccinated during 1914.

Mr. H. L. Fife: It is very lamentable that such numbers of children should be left like that.

The Chairman (Mr. John Smith): A great many people seem to think they know what to do better than the doctors.

S. C. L. (London).—The course suggested is not one which we should advise. Our correspondent should consider the matter more from a diplomatic point of view.

IGNORUS (Barnstaple).—Our correspondent is thanked for his communication, which shall receive notice.

AMBIGUOUS.

A STORY is told of a man in the North of London who had been invited to enlist, and who wrote as follows to the local recruiting committee:—

"I do not feel I ought to leave my wife while there are any single men left at home in this district."

JUMBO (Rotherhithe).—Dr. Howarth, Medical Officer for the City of London, in a report to the Corporation, mentions that in 1907 the percentage of tuberculous milk in the County of London was 12.9. Last year it had been reduced to 4.2.

PUNISHMENT FOR ILLEGAL OPERATIONS.

Mr. Justice Low, at the Central Criminal Court, in sentencing a woman to 12 months' hard labour for performing an illegal operation, said he thought that in the future, having regard to the condition of the country, these offences were very likely to meet with even more severe punishment than they had done in the past.

X. L. (Forfar).—The report states that in 1915 1,289 deaths were caused by accidents in the coal mines of the United Kingdom, an increase of seventy on the total for 1914.

SIR OSWALD MOSLEY'S DESIRE.

SIR OSWALD MOSLEY, of Burton-on-Trent, who died on October 10th last, in his will directs that his body is not to be screwed down in the coffin until a doctor has opened the veins in his neck and had certified the cause of death, and an open bottle of chloroform placed in the coffin.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 16TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF THE HISTORY OF MEDICINE) (1 Wimpole Street, W.)—5 p.m. (Books, MSS., etc., on view at 4.30 p.m.): Papers:—Mr. C. E. Wallis: Marat. Mr. Percy Dunn: An Oculist of XVI. Century (Andreas Laurentius). Dr. Dan McKenzie: Folk Cures by Constriction and Rings, with a digression into the Nature of the Soul. Dr. C. G. Cunston (Geneva): Portrait of Paracelsus.

THURSDAY, FEBRUARY 17TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF DERMATOLOGY) (1 Wimpole Street, W.)—5 p.m.: Exhibition of cases (at 4.30 p.m.).

FRIDAY, FEBRUARY 18TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OTOTOLOGY) (1 Wimpole Street, W.)—5 p.m.: Cases and Specimens will be shown by Mr. Sydney Scott, Dr. Dan McKenzie, Mr. Mollison, and others. Short Communication:—Dr. Dan McKenzie: Otogenic Facial Paralysis.

ROYAL SOCIETY OF MEDICINE (SECTION OF ELECTROTHERAPEUTICS) (1 Wimpole Street, W.)—8.30 p.m.: Clinical Meeting. Cases will be shown, also skiagrams and new apparatus.

MONDAY, FEBRUARY 21ST.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.)—9 p.m.: The Second Lethsonian Lecture will be delivered, on "The Effects of High Explosives on the Central Nervous System," by Major Fred. W. Mott, M.D.Lond., Hon. F.R.S. Edin., F.R.S.

Vacancies.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Castlenock (Dublin), Glaslough (Monaghan), Llanberis (Carnarvon), Aghadowey (Londonderry), Clackmannan (Clackmannan), Lyndhurst (Hants.), Newbridge (Kildare), Sedburgh (Yorks., West Riding).

Leeds Public Dispensary.—Lady Resident Medical Officer. Salary £130 per annum, with board, residence and laundry. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

The Royal Infirmary, Sunderland.—Lady House Surgeon. Salary £150 per annum, with board, residence and laundry. Applications to Thomas Robinson, Secretary.

Royal Albert Hospital, Devonport.—House Surgeon. Salary £150 per annum, with board and laundry. Applications to the Chairman of the Selection Committee, Charles W. Dickinson, Capt. R.N., Hon. Secretary, Royal Albert Hospital, Devonport.

Baguley Sanatorium for Treatment of Tuberculosis, Manchester. Second Assistant Medical Officer. Salary £250 per annum, with board and residence. Applications to the Chairman of the Hospitals Sub-Committee, Public Health Office, Civic Buildings, 1 Mount Street, Manchester.

London Lock Hospital, Dean Street, Soho, W.—House Surgeon. Salary £150 per annum. Applications to Henry J. Eason, Secretary.

West Ham Union.—Assistant Medical Officer. Salary £300 per annum. Applications to Thomas Smith, Clerk, Board Room, Union Road, Leytonstone, N.E.

Coventry and Warwickshire Hospital, Coventry.—Third Resident. Salary £175 per annum, with rooms, board, laundry, and attendance. Applications to John A. Rudd, Secretary.

Salford Royal Hospital.—House Physician. Salary £250 per annum with board and residence. Applications to George Ruddle, Secretary and Superintendent.

Salford Royal Hospital.—House Surgeon. Salary £200 per annum with board and residence. Applications to George Ruddle, Secretary and Superintendent.

Appointments.

ARMSTRONG, HUBERT, M.D. Vict. and Liverpool, Captain R.A.M.C. (T.), Honorary Physician, Liverpool Infirmary for Children, *vice* N. P. Marsh, M.B., M.R.C.S. (deceased).

BULL, G. V., M.B., B.C. Cantab., Certifying Surgeon under the Factory and Workshop Acts for the Hoddesdon district of the County of Hertford.

CURL, S. W., M.D. Cantab., M.R.C.P.Lond., Consulting Physician to the Clacton Cottage Hospital, *vice* Eustace Smith, M.D. (deceased).

WILLOUGHBY, W. M., M.D. Camb., D.P.H., Medical Officer of Health for the Port of London, *vice* Herbert Williams, M.D.Lond. (deceased).

Births.

FRASER.—On February 12th, at 75 Shooter's Hill Road, Blackheath, to Dr. and Mrs. A. Fraser—a son.

GOOD.—On February 9th, at The Hurst, Harborne, Birmingham, to Dr. and Mrs. Percy Good—a daughter.

MOORHEAD.—On February 7th, at South Godstone, Surrey, the wife of R. L. Moorhead, M.B., C.M.—a son.

PHILLIPS.—On February 12th, at Bethlem Royal Hospital, London, to Dr. and Mrs. Porter Phillips—a son.

PLATTS.—On February 12th, at 59 East Sheen Avenue, S.W., to the wife of Sydney Goodman Platts, M.B., a daughter.

SUTTON.—On February 12th, at 27 Clarendon Road, Southsea, the wife of Captain E. A. Sutton, Royal Army Medical Corps, of a son (stillborn).

Marriages.

BARRETT-WILEY.—On February 10th, by special licence, Sir W. F. Barrett, F.R.S., of Kingstown, Ireland, to Dr. Florence Wiley, of 31 Devonshire Place, W.

IRVINE-FORTESCUE-BODDINGTON.—On February 5th, at St. James's, Piccadilly, London, Captain Archer Irvine-Fortescue, Royal Army Medical Corps, eldest son of Dr. William Irvine-Fortescue, J.P., and of Mrs. Irvine-Fortescue, of Kincausie, Kincardineshire, to Ruth Olive, eldest daughter of Henry Boddington, J.P., and of Mrs. Boddington, of Pownall, Wiltshire, Cheshire.

JEFFREY-PAGE-ROBERTS.—On February 10th, at Strathfieldsaye, John Jeffrey, M.B., F.R.C.S.E., Jedburgh, to Cicely Frederica, daughter of the Rev. F. Page-Roberts, M.A., Rector of Strathfieldsaye.

PASCO-ROBY.—On February 12th, at St. Matthew's Church, Upper Clapton, Bernard Charles William Pasco, M.R.C.S., J.R.C.P. (Lieut., R.A.M.C.), son of Mr. and Mrs. William John Pasco, of Mill Hill, Middlesex, to Annie, daughter of Mr. and Mrs. George W. Roby, of Stamford Hill, N.

PEARSON-EARL.—On February 14th, at St. Augustine's, Norwich, Dr. S. V. Pearson, of Mundesley, to May Elizabeth, youngest daughter of Mr. and Mrs. Earl, of Norwich.

ROBINSON-HAWKES.—On February 3rd, at Christ Church, Corning, N.Y., Dr. E. H. Robinson, of Toronto, to Alice Luella Hawkes, of Inisicarra, Co. Cork.

Deaths.

CHARLES WORTH.—On February 8th, at "White Lodge," 66 Upper Richmond Road, East Putney, George Henry Charlesworth, M.D., J.P., aged 56.

MIDDLETON.—On February 7th, at 152, Bruntsfield Place, Edinburgh, Dr. Robert William Middleton, aged 63.

SAUNDERS.—On February 11th, at Staines Lodge, Staines, Fred. Herbert Saunders, M.D., eldest son of the late Lieut. Frederick Saunders, aged 67.

WALKER.—On February 7th, at Hurworth-on-Tees, Charles Edward, M.D., C.M. Edin., M.R.C.S. Eng., beloved husband of Annette Curtis Walker, in his 60th year.

WILLIAMS.—On February 12th, Dr. T. Hammond Williams, Oswestry, aged 56 years.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, FEBRUARY 23, 1916.

No. 8.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravants les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

At the beginning of last week, the following letter appeared in *The Times*: "All those who have any acquaintance with the subject will agree with Sir Alexander Ogston that 'the supply, from civilian sources, of medical officers for the Army is nearly exhausted,' and there is a growing feeling in the profession that the time has come when the War Office should mobilise all medical men, irrespective of age, and should enrol them with a view to utilising the part-time services for military work at home of those who are unable, either from age, physical disability, or financial reasons, to offer themselves for commissions in the R.A.M.C. It is believed that the greater part of the military work in this country could be done by such men, most of whom would probably be glad to give their help gratuitously, and that this would set free for service abroad many whole-time men who at present are employed in attendance on sick and wounded soldiers in the United Kingdom. Steps are now being taken to bring such a plan to the notice of the medical profession in London, and should it meet with general approval it is hoped that it may be adopted by the military authorities. The Emeriti of whom Sir Alexander Ogston speaks would then have the opportunity of doing useful work for the Army without any great interference with the services which they are already rendering to the civilian community and with very great saving to the finances of the nation." This was signed by two opulent general practitioners of Belgravia, Dr. Barcroft and Dr. Sydney Beauchamp, a distinguished physician, Dr. Robert Hutchison, and a well-known laryngologist, Mr. Seecombe Hett, none of whom, on the face of things, is in the least likely to have any real knowledge of how the war is affecting the rank and file of the profession.

A few days later the following appeared, to which the names of the same curious quartette were appended: "With reference to our letter which you were kind enough to publish in your issue of February 14th, we desire to state that we have had an opportunity of putting our views before Mr. Tennant and the

Central Medical War Committee, both of whom received us most courteously and sympathetically. It now seems to us desirable to postpone further steps towards securing more general service from the medical profession until the Central Medical War Committee's canvass for enrolment is completed." It seems a pity that these views, before being submitted to Mr. Tennant and the Central War Committee, were not submitted to the profession. If they had been, it is quite certain that their sponsors would not have been received "sympathetically," and, I fear, not very "courteously." But what on earth were these four humorists thinking about when they addressed their first letter to Printing House Square? It would be difficult to imagine a communication more completely out of harmony with the attitude of the vast majority of the profession towards the needs of the present crisis, and the way in which those needs should be met. It may well be that Sir Alexander Ogston is correct in believing that "the supply, from civilian sources, of medical officers for the Army is nearly exhausted," but that is not surprising in view of the notorious fact that the military authorities have been outrageously wasteful of those already enrolled. No semblance of a case has yet been made out for still further depleting the ranks of the medical men who remain available for the requirements of the civilian population.

In the opinion of the great majority of the profession, the solution of the present difficulty is to be found, not in the pressgang, but in efficient organisation. "S.O.S." who sends a spirited contribution to the present issue, wrote an article which appeared in the *MEDICAL PRESS AND CIRCULAR* as long ago as May 26th, 1915, entitled "Economise Your Medical Material." With real foresight he then pointed out the direction in which the military authorities were drifting, and pleaded for prompt and intelligent organisation. But the same policy of muddle and meddle which he then deplored has ever since continued to characterise the management of the medical side of military matters, with the result that we are now threatened with the "mobilisation of all medical men irrespective of age." It is inconceivable that

**The
Real
Solution.**

the members of the profession will tamely submit to so unnecessary and indefensible a course. In view of the sacrifices which have been and are still being uncomplainingly made, it would be nothing short of an outrage.

**The
Smoky
Fire.**

THE Central Medical War Committee has doubtless done its best to outgrow and disavow its sinister parentage, but it remains altogether unrepresentative and uninfluential, and, seemingly, quite unmindful of the medical situation as a whole. It appears to accept without any inquiry Sir Alfred Keogh's panic-begotten estimates of the military requirements, and hysterically seeks to supply these requirements without the slightest reference to the demands and interests of the civil population. Sir Alfred continues to cry "More, more," and the Central War Committee crouchingly harkens to his cry, without asking in return for any guarantee, either that the men are really wanted or that when obtained they will be suitably and economically employed. First-class surgeons are still in charge of typhoid wards; expert anaesthetists are still airing their heels in field ambulances at home; skilful physicians are still sighing over trench-feet; and all are spending most of their time in congenial and uplifting clerking. Were the present R.A.M.C. officers properly organised and suitably and economically employed, there would not be the slightest danger of the army being understaffed. That the fire is smoking badly is not a good reason for screaming for more coal.

The Facts.

WHAT are the facts? There are in existence about 30,000 practising members of the profession, of whom no less than 10,000 are already under military orders. The actual number expected and demanded by the authorities is 15,000. That is to say, four million soldiers are to get half of the doctors available, and some forty million civilians are to do the best they can with the other half. Of our home doctors, the proportion of men doing more work than their own is, on a very moderate computation, over one-half. Are these overworked men, irrespective of age, now to be mobilised and enrolled? The majority of them are doing much more than their share already; and that is more than can be said for many officers, junior and senior, of the R.A.M.C., here and at the various base hospitals. A good many of the latter declare that they are having "the time of their lives." The four breathless busybodies who addressed themselves to the Editor of the *Times* might have saved themselves the inglorious necessity for climbing down which Mr. Tennant's "courtesy and sympathy" seem to have imposed upon them, had they taken a little trouble to ascertain and digest the facts before making their preposterous proposals. To suggest that "doing useful work for the Army" is compatible with an absence of "any great interference with a practice" is merely to display an ignorance which is the more deplorable that it comes from members of the profession. I wonder if any of the four have ever seen an Army Form, or, having seen one, essayed the diversion of filling

it up. If 15,000 medical men are to be taken for the Army and 15,000 are to be graciously allowed to the civil population, where, I wonder, does the Navy come in?

**Deaths
from
Violence.**

DR. W. A. BREND, to whose books on "Death from Violence" I referred last week, writes to me to point out that his case against the verdict of "overlying" rests but very partially on the experience of the S.W. London Coroner's Court. That is perfectly correct. The experience of that Court was dramatic, and as it recalled a bygone controversy, the temptation to select it was too strong to be resisted. Dr. Brend's contention is that a large proportion of deaths otiosely attributed to overlying are really due to natural diseases, chief among which are bronchitis, broncho-pneumonia, convulsions and infantile debility, all of which conditions may to the inexperienced very easily present *post-mortem* appearances which are indistinguishable from those of overlying. Dr. Brend finds evidence for this belief in the fact that deaths attributed to overlying have a marked seasonal variation exactly corresponding with that of the conditions mentioned; that the correlation between overlying and overcrowding, measured by occupants per room, is not nearly so strong as has generally been believed; and that in France and Germany, where all *post-mortems* in cases of unnatural death are performed by expert pathologists, deaths from overlying are very few, an experience which agrees with that noticed on a smaller scale in the South-Western Coroner's district of London under the *régime* of Mr. Troutbeck.

**A
Bygone
Controversy.**

THE *régime* of Mr. Troutbeck, it will be recalled, was marked by a controversy which was needlessly embittered by that gentleman's singular want of tact. He insisted—and, in the view of a very large number, rightly insisted—that all the *post-mortems* in his Court should be performed by an expert pathologist, and most of this work was handed over to Dr. Freyberger, a very able man and a thoroughly reliable pathologist. The result was a storm of indignation from the local medical practitioners, who, not content with abusing Mr. Troutbeck, caused Dr. Freyberger to be included in the indictment, and suggested that the latter's pathological skill left much to be desired. Had all this happened after the outbreak of war, the pathologist's presumed nationality might have accounted for some of the animus; but it is a much older story, and most of those who then figured in the attack would probably now admit that the discovery of the cause of death from an autopsy is a very delicate matter which is best left to an expert.

**"Over-
lying."**

DR. BREND adds: "The fact is you can practically never prove that a case is one of overlying. The real reason why in the seven years which have elapsed since the Children Act was passed there has not been a single prosecution under the special clause in that Act is that there has not yet been a case in which proof that would satisfy a Court of Law has been forthcoming. What happens is this: the mother wakes up, turns about, and then finds the infant dead by her side. The popular belief that the mother lies right on the top of her child has been created and maintained by the very word 'overlying,' but in point of fact this condition is never met with." These are matters of the very first importance to every practitioner, and their masterly handling by Dr. Brend should ensure a wide popularity for his little book.

DOUBLE, DOUBLE, TOIL AND TROUBLE.

By S. O. S.

UNDER the auspices of the Central Medical War Committee, an attempt is being made to coerce the Medical Profession into military service, and it would be well to inquire into the causes which have rendered this course of action possible, and also into the constitution of the so-called Central Medical War Committee.

At the beginning of the war, offers of service from civilians met with scant courtesy from the authorities of the R.A.M.C., as the coffers of supply were filled to overflowing by patriotic volunteers, who were shuffled into posts for which in many instances they were totally unfitted. However, as the result of a surplus of material the R.A.M.C. authorities, who had acted without civilian advice (although there was in existence an advisory Board) congratulated themselves, after the initial deplorable catastrophe, upon their extraordinary efficiency. True, this efficiency was achieved by the employment of five or even ten men where one would have sufficed, and by the relegating of many capable clinicians to duties merely clerical.

Following the increase in the combatant units, the Army authorities became anxious lest the supply of civilian doctors should fail; and in this crisis they appealed to the British Medical Association. This body having deservedly lost the support of a large number of the profession, cast itself into the mould of the Central War Committee, and instead of advising the Director-General as to the best means of meeting the situation, assumed the office of an executive body, and bombarded the profession with forms and threats, insisting that every medical man up to the age of 45 should enrol as a candidate for a commission in the R.A.M.C. without respect for or discrimination as to the particular qualities possessed by the individual. Moreover, legislation has been threatened whereby all medical men up to the age of 45 will be "conscripted" into the Army if this original appeal fails in its object. The time has come both to question the equity of these proceedings and the authority from which these edicts have emanated, and to consider whether other and better means may not be substituted for them. It will need little argument to show that Parliamentary coercion of a section of the community in this connection will be grossly unjust.

Consider for a moment that medical men are wanted because they possess a certain scientific knowledge and skill, and therefore they of all the various professional classes are to be uprooted from their present positions and transplanted into spheres where their services may or may not be of greatest service to the community. No account is taken of the domestic disruption which may follow this procedure, or of the financial embarrassment which may face the unfortunate individual. If the Government have need of specialists in other directions, "hewers of wood or drawers of water," chemical experts or munition authorities,

do they compel them to accept a rate of pay which will barely cover their rent? It is true that war profits are taxed, but we have heard something of the extravagant scale of such profits which will well stand a whittling down of 50 or even 75 per cent., and still leave a handsome margin with the contractor. Are the lawyers who argue in the Prize Court over the prizes, so hardly won by our fleet, docked of their fees? Have they to forsake their homes and give themselves over body and soul to a Government department? The medical man is to receive quite different treatment: he is to accept what the authorities are pleased to call an adequate sum of £400 per annum, less income tax; his house is to be rendered desolate; his dependents are to face the *res angustæ* of private life; his practice is to be jeopardised—a practice which may have taken years to build up, and which depends solely upon his own personal efforts. No doubt coercive legislation would be achieved easily. The medical profession has ever lacked the forensic eloquence to plead its cause or the political cunning to further its interests, and although it has been accused of forming the closest Trades Union known when it refuses to accept some unqualified man whom journalistic enthusiasts have boomed and advertised, it is as a matter of fact ununited and incapable of resisting the injustices which may be inflicted upon it. Ill represented in the Commons—and those there cease to be medical men when they become politicians—a considerable section has recently been rendered inarticulate, owing to the fact that officers in the R.A.M.C. and Navy are unable to air their views and express their opinions. No part of the community has been or is more ready to carry out its duties in connection with the war than the medical profession, but throughout it has been hampered by want of a central organising body which it can respect and on whom it can rely. If such a committee representative of the profession could be appointed, on whom medical men could depend for the defence of their interests and for the help of the Government, the present crisis would pass. In effect, the War Office Authorities wish to obtain a great favour from the profession; but they demand it as a right and with threats. Our reply should be: we will concede the favour, but suitable terms must be arranged—yours are harsh and unreasonable.

What should our terms be?

Half-time men must be accepted and recognised in the various military centres under a proper system, and six months' service abroad should be permitted. There can be no great objection to this, as the average hospital appointment (resident) is for that period. A man might be ready to give up his practice for six months, but he hesitates at twelve—a period which finds him quivering on the brink of a financial precipice.

Discrimination must be exercised in the selection of men for the different posts—attempts to fit square pegs into round holes have ever been a feature of the Army Medical Service—and some organised attempt must be made to see that, as far as possible, suitable work is given to each applicant, so that such anomalies as surgeons acting as medical officers of health, or orthopaedic surgeons in charge of medical wards, shall exist no longer. Medical men should be allowed to do their medical work; the clerical labours apparently essential to the War Office, can be left in the hands of the R.A.M.C. personnel. Rank and uniform should be eliminated if possible; and civilians, unless serving at the front, should pursue civilian work in their customary manner. For those engaging on foreign service rank may be essential, but let it be in reasonable keeping with a man's professional position: to lump all medical men together and grade them all as lieutenants or captains is unjust and ridiculous.

CURRENT TOPICS.

The Arnott Medal.

NEVER since its inception has the Arnott Medal been the subject of such keen competition as this year. In normal times it is a matter of small difficulty for the committee of the Irish Schools and Graduates' Association to select an Irish doctor who has performed some brave act or distinguished service upon whom to bestow it. But these are not normal times; and many Irish doctors, who in the ordinary way would have passed their lives "unhonoured and unsung," have found in the European war an unlooked-for opportunity of proving their mettle. It was, therefore, no longer for the committee a matter of seeking a hero from among the common herd; they had to rather select one from a crowd of heroes! We understand that no less than sixty names, all deserving, were considered by the committee. The selected one has, therefore, every reason for pride. He is Captain W. F. B. Loughnan, R.A.M.C., L.R.C.S.I., L.R.C.P.I., D.P.H., Diplomate in Tropical Medicine and Hygiene, Cantab. He was born in Kilkenny in 1881, and is the son of the late T. M. Loughnan, himself a distinguished soldier. He was educated at Rockwell College, and studied medicine in the Royal College of Surgeons, Ireland, and at the Richmond Hospital. He qualified in 1904, and, having acted as assistant in the Coombe Hospital and been senior resident surgeon in Jervis Street Hospital, Dublin, he entered the Army in 1906. He served in India and Arabia, and held the appointment of specialist in the prevention of disease in Bareilly and Aden. He went to France with the original Expeditionary Force, and served through the retreat and the advance. He showed conspicuous bravery on several occasions, and among other acts he secured the severed artery of a badly wounded officer on the battlefield, and carried him to a place of safety under fire. He was at length severely wounded by the bursting of a shell near him while performing a like dangerous duty. He was rendered uncon-

scious, and lay buried in the *débris* till rescued by his comrades. The right brachial artery and some of the nerves were badly injured. He has been mentioned in despatches and awarded the Military Cross. No more worthy recipient of the medal could have been chosen than Captain Loughnan. We heartily congratulate him.

Lancashire's Birthrate.

At the quarterly meeting of the Lancashire County Council, held on February 3rd, Alderman J. Chadwick, Chairman of the Midwives Act Committee, referred to the steady decrease in the birth-rate during the last forty years from 36 per 1,000 of the population to 23 per 1,000. That decrease meant to Lancashire a loss of nearly half-a-million lives, or in exact figures 467,837 lives. The birth-rate and death-rate were getting very near one another, and in some districts the death-rate was the greater of the two. That state of things was an international evil which began in France, then came to this country, and had even invaded Germany, so that now the birth-rate of London was greater than those of Berlin and Hamburg. The Germans were getting very much concerned about it, and had adopted various means of dealing with the evil, even to the extent, it was said, of encouraging the marriage of brides of sixteen.

Much had been done in the direction of inquiry into causes, and also in the direction of reducing infantile mortality. In Lancashire it was found that 20 per cent. of the deaths of infants occurred in the first week, and 36 per cent. in the first month. In spite of these times of financial pressure, they were being pressed by the Local Government Board, and also by local authorities, to take steps in the matter, and he hoped that something would be done by the Public Health Committee to keep Lancashire to the front in this matter.

Presentation to Dr. Joseph Power.

IN our correspondence columns will be found a letter from Dr. Stephenson, of Carrick-on-Suir, calling attention to a proposed presentation to Dr. Joseph Power, of Ardfinnan, in recognition of his services to the medical profession in connection with the certification question under the National Health Insurance Act. Dr. Power was one of the first medical men in Ireland to recognise the importance of this question, and for the past three years he devoted himself with great energy and ability to the furthering of the claims of the profession regarding certification. At the request of the Irish Medical Association he wrote a pamphlet on the relation of Irish medical men to the Insurance Act, which was of service in putting the professional case before the public. Dr. Power did much to keep the profession together in its long struggle, and was one of the most active members of the Irish Medical Committee since its establishment; for the first year he was vice-chairman of that Committee. As a member of the several deputations which on various occasions represented the Irish Medical Committee, Dr. Power is one of the group to whose determination and

judgment the settlement of the certification question is so largely due. We hope that the response to Dr. Stephenson's appeal will be worthy of the profession and of Dr. Power.

Scarcity of Ship Surgeons.

WE notice in the *Glasgow Herald* that some of the passenger lines are having considerable difficulty in inducing medical men to take service at sea. This is quite understandable. In the past every young medico, when he graduated, considered a voyage as his first step in medical life, partly to see more of the world and partly for his health's sake. But these are abnormal times. When we can't get a graduate to act in the much-valued position of house physician or house surgeon in our large general hospitals, when we have to be doing with the help of a senior student—and sometimes not very senior at that—the shipowners must suffer from the shortage in the market also. Immediately the "boys" get capped with George Buchanan's touchstone, they want to be off to see the "fun." The remedy? "Will siller dae it?" We think it will.

Equanimity.

MENTAL fortitude, incumbent upon all, is especially so in the case of the medical practitioner—not alone for his own sake, in order to preserve the temperamental balance, but also for the benefit of his patients. In cases of continued illness, it is the anxiety arising from physical incapacity, even more than actual suffering, which causes the patient such acute distress: he looks to the medical adviser not merely for bodily alleviation, but in addition for intellectual support, and it is the combination of both lines of treatment which result in recovery. But let the sick man come to realise that the doctor's mind is as fluctuant and unstable as his own; that the same waves of peevishness and depression visit him; that his moral grip is equally spasmodic; and at once his own confidence is irretrievably lost. Rightly or wrongly, we think that the sphere of medicine is steadily widening to embrace eventually a domain up to the present dominated by philosophy—if dominated by any positive factor at all; and that, such being its future scope, none but those possessed of the rare capacity to see life steadily and see it whole can expect to be of utility therein. The ill-defined minor mental instability will, we believe, prove to be a malady of increasing importance—to be combated not by drugs, but by the too-often sneered-at therapy of Arnold—sweetness and light.

Re-examination of Recruits.

As "Truth" points out, there is bound to be hardship to some individual members in this re-examination of recruits. There is always a certain percentage of recruits on the borderland of inefficiency as regards health, and in examinations the personal equation tells largely. Different examiners have different standards—the same examiner may and does differ at different times in his attitude towards these doubtful cases. Further, as the pressure for men has increased, the standard has been lowered mainly because in such a large

army work can be found for those who are not quite up to first-class fitness. At the beginning of the war numbers of men were refused or sent for operation if the slightest varicose condition were found in the veins usually affected. Indeed, there seems to have been a crusade to discover this venous defect, and were it ever so slight, disqualification followed. Athletes who had made records were turned down because of an almost imperceptible varix of which they themselves were unaware. Per contra, a well-marked case of hip-joint disease was passed into the ranks without question. The examiners had too many to look after to do the work properly, especially as the recruits came in rushes.

Recognition of Medical War Service.

THE Royal Faculty of Physicians and Surgeons of Glasgow have made an alteration in their regulations for the examination to the Fellowship of the Royal Faculty in order to mark their sense of the value of war service given by members of the medical profession, and to facilitate the entry of those who render adequate war service into the Fellowship without unduly lowering the standard of qualification. Instead of two subjects of medical science being the scope of the examination, one alone will suffice, and this rule holds till five years after the end of the war. What is meant by adequate war service? Does it mean length of service, or having been within a minimum distance of combatant Germans? Will the fact of having worn khaki be adequate? What about the men working in Red Cross hospitals? Or will each case be settled on its own merits? Then no mention is made of the fee, whether reduced or raised. But that in the Royal Faculty will be treated as Mulvaney treated the elephant—"with outrajis contimpt."

What is a Hernia?

THERE is a clamant need for a clear definition of the cause or causes of ordinary hernia. Many cases are cropping up under the Workmen's Compensation Act, and opinions as to the effect of muscular strain or extensive force vary. In one court decision is given in favour of the workman who proves that he has had an accident, a strain, twist or awkward fall, and that he noticed the hernia first after said accident. It is argued that the accident caused an increase in the size of the hernia, and therefore legally is the responsible factor. It may even be held that the strain produced the hernia *ab initio*. Against that another court holds that it takes an infinite number of muscular efforts to produce a hernia, each effort producing its own infinitesimal increment in the growth of the tumour, and that the proved accident only brought an already existing but unknown swelling into the workman's ken. What the accident did was to fill the already existing sac to its limit and produce pain—if the said filling had gone further, strangulation would have ensued—which is quite another story. That would clearly have been an accident. But if an infinitesimal increase in the size of a hernia due to contraction of the abdominal muscles is to be held as the legal

cause of hernia, then what is to prevent a workman, after swinging a hammer once or twice, from stopping work on the plea that his hernia has become bigger and it is now a danger for him to work?

What would be useful would be the opinions of some of our outstanding surgeons (we bar physicians even if they are Medical Referees) as to

(1) What is a traumatic hernia; its frequency, causation, and appearance?

(2) What effect has a severe muscular effort on the size of the sac, and therefore on the growth of the swelling?

We cannot but think that it is unfortunate that the word "Rupture" is embedded in the lay mind, particularly in connection with this condition. Involuntarily the notion of something being burst or torn is a determining factor in the decision given in many cases.

The point is a fine one, but for dear logic's sake it ought to be made clear; if it cannot, then every hernia must be put down to "arising out of the workman's employment."

The Value of Inoculation against Typhoid.

WE quote the following from the *Broad Arrow*:—"The policy pursued by the Royal Army Medical Corps with regard to inoculation against typhoid is amply justified by the figures given by Mr. Tennant in the House of Commons lately. He stated that, from the beginning of hostilities to 10th November last, 1,365 cases of enteric fever were reported as having occurred among British troops in France and Belgium. Of these, 1,150 had been diagnosed after bacteriological examination. In 597 cases where there had been inoculation thirty-five deaths resulted; when there had been none, 115 deaths, or more than three to one. Such a marked difference cannot be explained in any other way than by reference to the work of Sir Almroth Wright and Sir William Leishman, who were so loyally supported by some of the most famous scientists of the day. In the field the value of the policy they advocated was equally well understood, and was carried out with comprehensive thoroughness. Not only was every man who consented inoculated against the disease, but he was further protected against infection by the precautions taken with regard to sanitation, water analysis, and water purification. Then a careful search was made for 'carriers,' the technical term for persons who, while keeping well themselves, harbour the bacillus of enteric fever in their bodies, and so are liable to spread infection. In the handling of food they would be particularly dangerous, so that in the commissariat department, the search for 'carriers' is always keen. To estimate the debt we owe to science and the splendid organisation of the Army Medical Service in connection with disease we have to compare the relatively small record of the present great war with the shocking records of wars of only a generation ago."

Temperament.

FACILITY of temperament is a blessing which cannot be over-estimated. If we construe it aright, it consists in a capacity to dismiss from consideration difficulties which cannot be overcome—in a sublime faculty to accept possibilities, if they be pleasant, without question, or analysis to their ultimate and too frequently arbitrary basis. The converse type, the man of difficle soul, affords a picture which we fear is more common and, alas, upon the increase. He is profoundly conscious of the less happy side of life, realises the still sad music of humanity to the finger tips, and where jocund emotions cross his spirit bids them stand and

deliver answer to the eternal questions of whence and whither. He ventures no enterprise—human or divine—foreseeing each obstacle in meticulous detail. He makes no confidences—are not they customarily betrayed? He forms no friendships because the inevitable anxiety and responsibility attendant upon intimate human intercourse outweighs for him the gigantic spiritual gain. He is afraid, in a word, of developing the activities natural and necessary to the growth of the human soul. Not for him the free heart and forehead of Ulysses. But the opportunist—in the best sense, tries all things, proves all things. His existence is a quest, a great adventure. He is a schoolboy playing truant in the fields of life upon his shadowy and unknown master. His is the philosophy of the apostle—"Hold fast that which is good"—which finds its modern archetype perhaps in the immortal Robert Louis Stevenson.

Miners' Phthisis in South Africa.

THE government mining engineer of the Union of South Africa writes the following in his annual report for the year ended Dec. 31st, 1914:—"The monthly returns of the Miners' Phthisis Board show that the number of awards to miners for phthisis, both in the initial and in the more advanced stages, is beginning to fall off substantially. This is an indication that the disposal of the large number of cases of miners' phthisis, accumulated over many years, is at last nearing completion. In future, therefore, the returns of the board ought to reflect the current position, and to be an increasingly reliable index of the extent to which success is being attained by the more thorough measures initiated during the last few years for the eradication of the disease." The president of the Chamber of Mines recently pointed out that since the commencement of the Miners' Phthisis Board on August 1st, 1912, until April 30th, 1915, the total number of applications disposed of by the board per quarter had decreased by almost exactly one-half, which was a very large decrease—even when it was remembered that at the commencement of the board's operations the accumulation of past cases would naturally inflate the number of applications received. The same decrease has been maintained for the quarter ended July 31st, 1915.

PERSONAL.

MR. J. W. KNAPMAN, Librarian to the Pharmaceutical Society, has completed 50 years' service in that position.

LIEUT.-COL. E. JENNINGS, I.M.S., has been appointed to act as Civil Surgeon, Belgium, in addition to his military duties.

CAPT. R. H. BOTT, I.M.S., Professor of Surgery, Medical College, Lahore, has been appointed Professor of Operative Surgery.

MR. C. WARBURTON, M.A., Christ's, has been appointed Demonstrator in Medical Entomology at Cambridge until November 1st, 1918.

MR. H. H. BRINDLEY, M.A., St. John's, has been appointed Demonstrator of Biology to Medical Students at Cambridge until September 30th, 1920.

MR. A. W. BAIN has been elected as Chairman of the Harrogate Infirmary in succession to the late Mr. J. W. Wilson. Mr. Bain, who is an ex-Lord Mayor of Leeds, and resides at Harrogate, was specially invited to join the Board and to accept the chairmanship.

ORIGINAL PAPERS.

THE PHYSIOLOGY OF SCYBALA.

By SIR JAMES F. GOODHART, Bart., M.D., F.R.C.P.

INTESTINAL bricks and their mortar! Who pauses to think about scybala, beyond the fact that they indicate constipation and need a purge? Yet they may be instinct with physiological teaching if we can but read it. Of late years the investigation of the intestinal secretions and excretions has gradually asserted itself, and valuable knowledge of an exact kind concerning them is accumulating both from the side of biological chemistry and bacteriology. The bio-chemist has probably taught us most, although his line of research is not one of the most pleasant to follow. Bacteriology, on the other hand, would seem to lend itself to dreams of "The garden that I love" and to poetic imaginings of intestinal "flora." But intestinal horticulture is hardly in sight yet; we are all still busy practising our pothooks, outlines, and elements of perspective, and one is as yet rather framed in the mould of

"Oh, give me air and syringe me with waters of Cologne!

Dry as a Hortus siccus run to seed, and over-blown."

But neither chemical nor bacteriological aspect is my purpose now; I propose to ask a question or two of scybala from the point of view of what I may perhaps call general intestinal function.

A man, say—for choice—is troubled with a bad pain in his abdomen, somewhere behind the umbilicus, or rather above it. It is chiefly a night or early morning ache, yet, more or less there is always a something there. All sorts of suggestions are of course made as to possible causes, but no evidence points definitely to any certain diagnosis. There is constipation, no doubt, and scybala have been noted as present in the bowel, and have been removed *secundum artem*, but—and this is my point—others have quickly appeared. Such an one shall tell you that within a short time the bowels acted with perfect regularity, and the condition is attributed to anxiety or worry. I have elsewhere mentioned just such a case. A man, who being of absolutely regular habits, had a severe nervous shock in a railway accident, and thereafter at once began to pass scybala of stony hardness, and no doubt my reader can supply many a similar picture from his own notebook, for it is indeed one of the commonplaces of medicine.

What does this mean? To murmur "constipation," and content oneself with a purge does not go to the root of the matter, for when one formation is cleared out another comes along. Constipation no doubt favours the formation of scybala, especially in the sigmoid, but the occasional suddenness and rapidity of their formation is to me the interest of the condition. No mere sluggishness of the intestinal muscle will explain this. Though you clear them out, on come others; diet helps little; you may stuff and feed on anything and everything and no beneficial effect is very evident, and unless the bowel be kept constantly on the run scybala will be present.

Putting, then, diet, both as regards quantity and quality, and drugs out of present question, it

would seem that the phenomena must be due to the too rapid absorption of the watery constituents of the contents of the bowel, or to cessation of the formation of the succus intestinalis and mucus.

As regards a too rapid absorption of the intestinal fluids, there is, perhaps, not much to be said, yet there are interesting suggestions as to why it might be found in some of the phases of unnatural hunger that are met with in various deranged states of the abdominal nervous system. There is a condition well known of extraordinary and uncontrollable hunger that will attack some nervous subjects, perhaps when they are gouty, at any rate when they are not quite well, or before an attack of migraine, and which may well be due to a too rapid absorption of the contents of the stomach and intestine. I allude to this condition somewhat sympathetically because I often say that one who thus suffers may perhaps know something of the cravings of the drunkard from an appetite of this kind—certainly it is most difficult to resist. One might almost describe it as the luxury of sorrow, for although hunger is a pleasant sensation, this verily is a hunger pain. I remember many years ago an old friend, then demonstrating daily in the *post-mortem* room at half-past two, describing to me the extraordinary shifts he had been put to to provide himself with a lunch that under the stimulus of mental excitement would not leave him empty and destitute in the middle of his lecture. If the drunkard's craze is anything like it, I can understand and sympathise with the dipsomaniac.

There are other clinical facts that bear upon the same question, such as the well-known cravings of pregnancy, also what I have elsewhere ventured to call hungry bowels, a restless abdominal condition where purgatives are in constant use to keep a bowel empty when its health and function depend upon its being moderately full, and where the patient will sometimes come and tell you spontaneously that he or she is only comfortable when the bowels have not acted. There is a habit of purging that induces constipation. So it seems not unlikely that too rapid absorption plays a part in some cases of scybalous formation, although perhaps not so much in the class of case now before us.

Nor do I know as regards the sudden cessation of the formation of the succus intestinalis that we are much better off as regards actual knowledge. We seem to think we know a great deal about the existence of a catarrhal state with an *excess* of the intestinal mucus, and in consequence are apt to lay far too much stress upon it. Having diagnosed a case as one of mucous colitis, it is forthwith locked up in the catarrhal and dysenteric group of intestinal ailments, treated in one of the more or less routine methods, of which the Plombière douche is perhaps the commonest, and then we would have done with it, only that it won't let us, for it is a most exasperating malady both to patient and doctor—in fact, both too often lose their heads over it, and I have often been shown a stool,

as that of mucous colitis, when there has been no more mucus than one might expect to see in quite healthy conditions. As if it were a crime on the part of the mucous membrane to perform its natural and necessary function; and more or less—one day this, another day that—and not within the range of a natural and common oscillation. We have certainly not got at the back of mucous colitis, as some seem to think, when an excess of mucus is present in the stools.

But what do we know about dry bowels? Well, we know of a *dry* tongue, and a *dry* mouth, and a *dry* throat. We can see these, and they may perhaps be taken as presumptive evidence of the occurrence of a similar condition lower down in the intestinal tract. For the rest I can most conclusively appeal to a piece of experience that only those in the habit of examining the rectum as a means of diagnosis will fully appreciate. They will readily acquiesce in the statement that a dry mucous membrane in the lower bowel is by no means uncommon, though, as far as I know, it gives little or no discomfort. At any rate, I have frequently remarked its presence where no complaint has been made of local discomfort.

In such cases the mucous membrane is quite dry and generally coated with a thin adherent layer of faecal matter. A similar condition is often seen in the colon in making *post-mortem* examinations, but this might possibly be a condition produced after death. One may well suspect, however, that some such state is not uncommon during life, and that if so, it has to do with this or that alteration of the intestinal discharges. It is the fashion just now to suggest an *absorption* toxæmia for all the results that follow upon intestinal derangement, but as I listen to all that is said on that behalf I wonder! Rather do I think that the *absence of absorption*, the *absence even of secretion*, claims no small share in abdominal malaise. I have appealed to the cleaving of the tongue to the roof of the mouth as a something we have all experienced in some degree as an immediate result of a sudden nervous shock or excitement, and I think it probable that a similar occurrence must be present in many of the intestinal disturbances and their consequences that are met with so commonly in general practice. The scybala thus formed come about as the effect of a splanchnic paralysis, the more or less of which will sufficiently account for the hundred and one different sensations and symptoms that are to be heard of in the neurasthenic patient and not alone in them.

A splanchnic paralysis of this kind is probably seen at its worst by alienists in profound melancholia, where not only is there the most obstinate constipation, but extreme emaciation also, showing that intestinal absorption and secretion both fail, as well as hepatic and other glandular actions.

Whether, then, scybala be the result of too rapid absorption or defect of intestinal secretion, it seems probable that in either case splanchnic control is behind it all.

Nor is the nature of abdominal and intestinal pain beside the mark in talking about scybala, for the passage of hard concretions along the colon is associated in some with very violent pain, as is also the formation of gas. In his Goulstonian lectures before the Royal College of Physicians, Dr. Hertz gave some careful observations made by him to show that the intestine has none of what goes by the name of common sensation—that is, if you pinch it, the stimulus is not recognised as pain. This is no doubt true; it is true also of the heart, and probably of a good many of our inward parts. I think one might almost say that we knew this

already, for it does but illustrate a law of our being, that every pain is more or less special—peculiar, that is, to the region wherein it originates, or to the part wherein it is perceived. Thus, common sensation—a surface or skin pain—is a soreness, if it be possible to describe pain; then there is a serous membrane pain of pleura and peritoneum still more difficult to convey by word picture, because, perhaps, it is a mixed product of separate areas; different conditions thus combine, such as acute stitch, distension, collapse, all liable to vary much in different individuals. Again, there is the hot, burning wave of pain suggestive often of the passage of grit along a narrow muscular passage; there is the dull, dreadful ache of the sympathetic ganglia, well illustrated by the pain of angina, thoracic or abdominal; there is the pain of lumbago, cervical or lumbar; there is the neuralgic type of pain in neuritis of such parts as are subject to much energy of motion, such as sciatica, humeral neuralgia and tic; there are the various forms of headache, by no means like pain of other sorts; and also the various disturbances of special sense which, although they are not pain, are only not so because the disturbance they undergo is their pain and their only form of speech. I take it that the auditory nerve can only express pain as an acute exaggeration of its special sense, and sight, smell and touch in like manner. Thus all the varied nervous distributions are strung to their own concert pitch, and the intestinal nerves, as Dr. Hertz quite rightly points out, are only capable of a muscular pain, which is that of a cramp—let him describe it who can—acute or dull, sickening, depressing. Scybala of moderate size will often produce some little gripping pain, dependent upon the muscular effort on the part of the bowel to rid itself of them, but the larger masses, of which I am now more particularly thinking, seem to give very little, for the bowel is, as I suppose, paralysed and makes little effort. I have occasionally seen a case where scybala were supposed to be present with intestinal obstruction, but this is rarely the case; experience would teach that for the most part they are evidence against it. This leads me on to make the very obvious, but necessary, remark that these pains, and sensations that are equivalent to pain, vary *ad infinitum* in character or intensity. So much is this the case that, interesting as most of them are to think upon and extract a meaning from, it is impossible to attempt any detailed description of them. One or two of the commoner forms can, however, be mentioned. And first of all I would speak of the dull depressing ache about or somewhere above the umbilicus already mentioned. It will often last more or less continuously for many days together, perhaps a week or two; some individuals are subject to it from time to time as a part of their life history. It is not altered much by food one way or the other, nor bettered by aperients. It disappears slowly—not flattering our treatment much. I cannot but think that this is an anginal form of ache emanating from the abdominal brain, a headache in the abdomen, and that it is associated with spasm or cramp of the colon. Probably this condition often passes under the name of flatulent colic, but flatulent distension is not a prominent feature; there is no doubt the *feeling* of distension and heaviness, and there may be, as is so well marked in many a case of angina pectoris, the eructation of wind, and even discharges of gas per anum, but these bring but little immediate relief to the pain.

Allied to this condition, but by no means the same thing, for there is not the same deadly ache attaching to it, that is so de-energising, there are many who describe a persistent discomfort and more or less actual pain, as of a muscular

ache or soreness under the left ribs. This is associated with more or less flatulence, and with it there is likely to be constipation associated with spasmodic contraction of the colon, and the passage of tape-like stools that frighten a little knowledge into the fear of cancer. The descending colon or sigmoid flexure can often be felt thick and cord-like in the left loin or groin, and is tender. I imagine that these conditions of the colon must be due to some disordered state of the nervous supply to the bowel, and leading to a tonic spasm similar to that seen in the voluntary muscular system in tetany, with which, it may be observed, disturbances of the colon are well known to be associated.

And when talking upon such intestinal states as these, there is another not far removed from them which I try to bring in because I do not think it has ever received any pointed description, but which must be, I think, by no means uncommon in general practice, a general malaise that seems as if it might be akin to *mal de mer*. Certain people are subject to this condition from time to time throughout their active years. If it has never been described one may hazard the reason to be because it is indescribable. The patient himself can give little precise clue to his feelings, but it appears to be a life-is-not-worth-livingness that emanates from the splanchnic area of the abdomen, and is associated with evidences of all the secretions of the body having gone wrong. It is one of the group to which the term abdominal migraine seems to me fitly to apply, and as a morbid anatomist one's mind hovers over the pancreas. I am far from wishing to see things with a coloured vision, and such conditions as I allude to may be, in their origin, a toxæmia, intestinal or uric acid, or what not. They may equally be initiated, I daresay, by one of the many "itises" that exploit this part of the body, but if so they do not seem to respond to treatment undertaken on such lines; on the contrary, they have a tendency to run a certain course, irrespective of treatment, so that one is inclined to think of some such influence as a climatic one rather than organic change; and of watts, ampères or volta, if there be such a measure, or their equivalent, of nervous current, than actual wear and tear.

But thoughts such as these are as shifting sands. Well do I remember that Sir Samuel Wilks would almost turn up his kindly nose if anyone began to talk about the sympathetic nerve. Steeped in the facts of the *post-mortem* room, the vasomotor system did not come within his view, and he rightly held that as yet we know nothing about it. More than that, it will be a long, long time before we do know enough about it to formulate our knowledge, and the scientific mind will have nothing to say upon agnostic matters. Yet, meantime, we doctors have to deal with deranged splanchnic function, and provided we do no more, there can be nothing but good to be got from guesses at truth. There can be no question that we all possess an abdominal brain and nerves; that this nervous centre is there to express itself in initiative and control; that it has extraordinarily sympathetic relations with the cerebro-spinal system; and therefore if disturbed or worried, some signs will be given if we can but read them.

In default, then, of adequate morbid anatomy, the times would seem even still to call for careful observation of morbid function by the physiologist and the physician, and betimes even, perhaps, for the guarded use of their imaginative insight, taking up its position at the point where, for the present, morbid anatomy has perforce to abandon it. At

any rate, one may say this: that of all the interesting parts of the human body, the abdomen is probably one of the most so from the extraordinary vagaries of nervous action that are to be heard of therein. Would that circumstances would allow of the study of such maladies free from the terror of treating them that lies behind it, and unfortunately for meditation, fortunately, perhaps, for those who ask for relief from their distressful state, surgery has of late from a somewhat divergent point of view rather queered the physicians' pitch, rushing in where others heretofore had feared to tread and asked for time. I would be on the side of those others in this matter, hence these rambling thoughts when no sick one is ruffling the waters of my mental pool.

A NOTE ON THE CERTIFICATION OF INSURED PERSONS IN IRELAND.*

BY ROBERT J. ROWLETTE, M.D.DUB.,
F.R.C.P.I.,

Physician to Jervis Street Hospital, Dublin.

AMONG the most troublesome problems arising out of the administration of the National Health Insurance Act in Ireland, in so far as it concerns medical men, has been that of obtaining evidence of incapacity for work such as to entitle an insured person to sickness or disablement benefit. The problem has been one especially affecting Ireland, owing to the absence of the medical benefit in this country, since in Great Britain the machinery set up for administering the medical benefit was readily made available for furnishing medical evidence of incapacity.

The Act itself nowhere lays down the nature of the evidence on which a society is to decide whether a member is entitled to benefit or not. Approved societies are authorised, however, with the consent of the Insurance Commissioners (14 (13)) to make rules with regard to, *inter alia*, "notices and proof of disease or disablement, behaviour during disease or disablement, and the visiting of sick or disabled persons." Moreover, special powers are given to approved societies in Ireland as regards the obtaining of evidence (81 (13)) :—"Rules of an approved society or insurance committee under this part of this Act may provide for the inspection of medical relief registers by officers of the society or committee at all reasonable times, and for the furnishing to the society or committee of such medical certificates as may be necessary for the purposes of the administration of the benefits administered by the society or committee, and for the payment by the society or committee to duly qualified medical practitioners in respect of the furnishing of those certificates as the Irish Insurance Commissioners may sanction, and all payments so made by the society or committee shall be treated as expenses of administering the benefits aforesaid." As far as I know, no approved society in Ireland has ever taken advantage of this clause to pay for medical certificates, although several have employed medical advisers to assist them by their judgment as to the merit of claims. Up to the present, where a society has demanded a medical certificate as evidence of incapacity, it has thrown the onus of obtaining such certificate on the insured member himself.

In the absence of any attempt by the societies to furnish themselves with satisfactory evidence of incapacity of their members, it was clear that the State would have to take the matter in hand.

It may be well, in the first place, to discuss what possible methods there are of obtaining evidence of

* Read before the Section of State Medicine in the Royal Academy of Medicine in Ireland on Friday, January 7th, 1916.

incapacity, and to compare their respective merits, from the points of view of efficiency, public economy, and professional ethics. It will hardly be questioned, in the first instance, that evidence of incapacity obtained from a medical man is more likely to be trustworthy than that obtained from a layman, and I will not waste time in labouring this point.

Assuming, however, that medical evidence is required, how best can it be obtained? There are three possible sources—the medical man in attendance, another medical man who is not engaged in practice, and a medical man who is engaged in practice. It is clear that the medical man in attendance is in the best position to form a just opinion of the condition of his patient. He knows the history of his illness, very probably his previous history, and he watches the progress of the case from day to day, or from time to time. His opinion, therefore, if honestly given, is likely to be the best. It has been suggested, however, that the opinion may not always be honestly given, that the medical man may be swayed by kindness to his patient, or by interest in prolonging his attendance. It is hard to disprove these suggestions, though it is not for a moment to be believed that such influences would affect many members of our profession. It is worth remembering, however, that in Ireland a very high proportion of insured persons are attended by dispensary medical officers, who are under no temptation to prolong their attendance beyond what the condition of the patient requires. Again, in the Poor-law Service medical officers have the power of ordering outdoor-relief for the sick poor, and it has never been suggested that they have exercised this power in any other than a careful and proper spirit. It is fair, therefore, to conclude that as regards efficiency the medical attendant stands first.

As regards economy, the case is easier. The medical attendant is already seeing his patient regularly, and the additional labour required from him in order to furnish certificates is not comparable with what would be required if a medical man were to visit the patient merely for the purpose of certification. It costs the public less to commit the two duties of treatment and certification to one man than to occupy two men with tasks which overlap. As a practical matter it would be nearly impossible to maintain a sufficient staff of whole-time officers to do all the necessary certification work.

Next, as regards professional ethics, one does not need much imagination to figure the difficulties which inevitably arise if one medical man is to visit and investigate the condition of the patients of another medical man in his absence, and without his assistance. In some cases, in order to form a just judgment of the patient's condition, it would be necessary to interfere with dressings or apparatus, and so far, perhaps, to interfere with the course of treatment. Even with the greatest care and tact it may be difficult to refrain from observations which may be regarded by the patient as reflecting on the treatment advised by the medical attendant. When the certifier is not an independent whole-time officer, but is a practitioner in active competition with the medical attendant, such evils are magnified tenfold. Even if he be a man of absolute honesty and sound judgment, insured persons will inevitably think that they will get their benefit more readily if they are his patients than if they are not. The confidence of the public is necessary, and by the facts of his position a part-time certifier is deprived of this from the start. If he be a man at all prone to take unfair advantages of his rivals, temptations

to undermine the confidence of their patients and otherwise to interfere with their practice are overwhelming. I need not point out that the arguments I have here put forward have been amply supported by the events which have unfortunately come into our experience in the last few years.

From all points of view—efficiency, economy, professional propriety—the best evidence of incapacity is to be obtained from the medical attendant.

Nevertheless, it is only right that if either party—the approved society or the member—feel aggrieved by the decision of the medical attendant, there should be power to claim a second opinion. The wise medical man does not claim infallibility, and he will be glad, in doubtful cases—and many such arise—to have the assistance of the judgment of another. But it is essential that the second opinion should be that of a man of standing, whose skill and character command confidence, and that he should hold his position independently of the favour or control of any approved society.

Considerations such as I have mentioned have formed the basis of the claim made by the profession in regard to this problem during the past four years. The profession has made two demands—

(1) That primary certification of incapacity should be in the hands of the medical attendant; and (2) that the remuneration should be adequate. On the point of referees, the profession had said:—We do not ask for referees, but we will welcome their appointment, but we insist that they should be men of character and standing.

I can run very briefly over the history of the tedious struggle which has taken place before these demands were granted by the establishment of the system which came into force on the 1st January of this year.

The Insurance Act came into force in July, 1912, and at the beginning of 1913, an annual grant of £50,000 was made available for payment for certificates. The grant was regarded as inadequate by the profession, and the proposals made on the basis thereof were refused by the profession in the greater part of Ireland. In Belfast and certain other northern areas, and in some areas in the south and west, the proposals were temporarily accepted, and a scheme based thereon has been working with fair success. This is what is known as the "panel system," and it is necessary to explain it briefly. A sum of money, calculated at a capitation rate for insured persons in the area, was assigned to each area. The rate varied from 9d. *per caput* in Belfast and other urban areas to 2s. *per caput* in the most inaccessible rural areas. Every insured person was to choose a medical man by whom he expected to be certified, and the medical men were to be paid in proportion to the number of insured persons who exercised their choice in his favour. This scheme was regarded by the medical profession as satisfactory in principle, but, as a matter of fact, in very many cases no real choice was exercised by the insured person, the names being assigned in mass to certain medical men by the local agents of the approved societies. In this way it happened that the medical attendant was very often not the person who actually certified. Nevertheless, speaking generally, the system did not work badly, and in Belfast in particular, both the profession and the officials of the societies expressed their satisfaction with it. The refusal of the greater part of Ireland to accept the system made it clear that it had no real permanence, and consequently it never got a fair chance to prove its worth.

This refusal of the greater part of Ireland to accept this system was based on a conviction that the remuneration was inadequate. In these areas, comprising about three-fourths of the country, the Com-

missioners attempted to solve the difficulty on a different principle.

They appointed a number of medical men—some 170 in all, I think—under the title of "medical advisers," or "medical certifiers." These practitioners were part-time officers in receipt of fixed salaries, but it is not clear what duties they had to perform. It was generally understood that their duty was to furnish evidence of the condition of all insured persons who were referred to them, but this was expressly denied, as regards some of them, in certain documents issued by the Insurance Commissioners. In Dublin, for instance, the Commissioners declared that "these officers have not been appointed with a view to assisting the individual members of approved societies to obtain sickness benefit, but in order that an approved society shall not be obliged to continue to pay sickness benefit in cases where the members receiving such benefit are, knowingly or unknowingly, capable of work." In other words, the duty of the "adviser" was to act as a referee, and the onus of producing primary evidence of incapacity was still left on the unassisted member. Reasons have already been given for believing that even under the most favourable conditions such a scheme as this would not be a success. But the conditions were anything but favourable. The medical profession, holding to its cardinal principle that the medical attendant should be the certifier, disapproved of the system and, as a consequence, few medical men of reputation cared to undertake the work, and the staff of certifiers was not only insufficient in numbers, but the character of many of those appointed was not such as to command public confidence.

In spite, however, of the protests of the profession, and the injustice inflicted on the insured, this condition of affairs lasted for more than two years. It is only within the past few months that the decision to abolish both the panel and the certifiers has been made, and to establish the system which has just come into being.

The new scheme provides that every medical man who chooses to do so shall have the right to furnish to his patient on demand evidence of incapacity or capacity, and that he will be paid for furnishing such evidence. Moreover, it expressly prohibits a medical man from signing a certificate for a patient who is at the time under the care of another practitioner, except in certain well defined cases. The provisions bearing on these points offer a fair safeguard against interference by one practitioner with the patients of another, and fully satisfy the principle for which the profession has fought, as to the right of the medical attendant to certify.

The annual grant now available is between £90,000 and £95,000, being a capitation rate of 2s. 6d. per insured person. This is to bear the expense not only of the primary certification, but of referees or second opinions. It is distributed to the different parts of the country at rates varying from 1s. 3d. to 2s. 6d. per insured person. The final mode of distribution as between the several practitioners in a particular area is not yet decided, the Commissioners being desirous of gaining some experience of the working of the scheme before coming to a decision on this point. They have, however, promised to consult professional opinion and not to decide on a scheme which is not acceptable to the profession.

Unfortunately, it is not possible at the moment to make the scheme complete by the appointment of referees. The Commissioners have properly felt that in the absence of so many practitioners on the service of the country, it would be inopportune to create a number of important civil service posts.

Consequently, this part of the scheme must stand over for the present, but the Commissioners promise to proceed with it at the earliest moment, and in their choice of candidates to consider nothing but professional merit.

Such is the scheme now in force in this country. Its success depends to a great extent on the hearty and honest co-operation of our profession, all the more in the temporary absence of provision for referees. It is, I think, incumbent on every medical man whose practice touches the insured classes, not only to join in the scheme as a certifier, but to take his part in moulding the professional conscience to condemn as a crime any careless or dishonest certifying. The General Medical Council has already warned registered medical men of the danger of issuing misleading certificates.

There are many points in the new scheme which entice to discussion, but I have already exceeded the reasonable limits of your patience. I have thought it better to give a general sketch of the problem than to enter into details of history—much of which will, I hope, soon be forgotten—or to enter into a minute discussion of the new scheme. It is, however, a source of deep gratification that the painful and bitter struggle of the past few years has been ended by the success of principles which the profession held dear. We can look forward to a cessation of strife and ill-feeling within the profession, and a cordial and friendly co-operation with those who are responsible to the country for the administration of an Act which, whatever be its faults, has great possibilities of good.

TRENCH NEPHRITIS.

By W. LANGDON BROWN.

In introducing the discussion on this subject at the Royal Society of Medicine, Dr. Langdon Brown said that acute nephritis is not a common disease in civil practice; at St. Bartholomew's Hospital, with an average annual admission of 7,000 medical cases, there were in five years only 26 cases in men of military age. And whereas dysentery and typhoid had dogged most campaigns in the past, acute nephritis usually did not. It was very rare in the South African War, but in the American Civil War there was a very considerable outbreak, which assumed epidemic proportions between March, 1862, and March, 1863. Throughout that war there were 14,117 cases, and it was interesting to recall that the military conditions resembled those of the present war. There was the dash forward of the Confederates, which was checked and followed by prolonged trench warfare. The epidemic in the British Expeditionary Force had not reached such dimensions, but up to the end of June, 1915, there had been 1,062 cases, and they had not been diminishing since. Reports from Vienna showed that the enemy were also affected by the disease, which started about the same time as in our Army, and as in the American Civil War, *i.e.*, in March.

Exposure as a cause was negated by the facts of the rarity of the disease in South Africa and in the Russo-Japanese War, and also because it was not until the weather began to get warmer that the disease assumed epidemic proportions. A climatic cause would not explain an epidemic such as that in the American Civil War, which lasted twelve months and did not recur in subsequent years of the war. Various other causes, such as the water supply, chlorination of the water, intestinal toxæmia and acidosis had been suggested, but could be excluded. Only a few cases could be explained as an exacerbation of chronic nephritis. The

French Army surgeons had suggested that the epidemic was due to a suppressed form of scarlet fever. In this connection it was interesting to note the immunity of the Indian troops from nephritis, as the inhabitants of India enjoyed comparative immunity from scarlet fever. Although this theory would not stand examination, it was important to note that the urinary and pathological changes in trench nephritis and scarlatinal nephritis were closely similar.

Various chemical tests had been employed which showed that as in a nephritis of infective origin, trench nephritis was glomerulo-tubular in distribution, and this had been confirmed by *post-mortem* examination in some of the few fatal cases. As to the nature of the infection, cultures from the blood, faeces and urine had yielded no positive bacteriological results, but Dr. Mackenzie Wallis had obtained suggestive, though not conclusive, evidence of an ultra-microscopic filter-passing virus by injecting the urine, which had been passed through a Berkefeld filter, into rabbits and monkeys. A severe illness was produced after a latent period of eight days, which would exclude a mere chemical cause, and corresponded to the incubation period which had been observed clinically. Wassermann's reaction was positive in about one in every three cases. This did not mean that such patients were necessarily syphilitic, as other animal infections would produce a positive reaction. A filter-passing infection was believed to be animal in nature.

A number of the cases had had symptoms of fever and malaise before the nephritis, but usually œdema was the first symptom. Shortness of breath had been a striking and very common symptom, starting at the same time as the œdema, but ceasing after a few days. Bronchitis was common, and a fair proportion of patients had complained of sore throat. Great reduction in urinary secretion was not so common as in ordinary acute nephritis, while great variations in the quantity was not uncommon. Hæmaturia sometimes continued long after all signs of active inflammation had subsided. Leucocytes, epithelial, granular and fatty casts were usually found in the urine, though blood casts and fatty casts were rare. Uræmic convulsions occurred occasionally, but generally yielded to free venesection.

A considerable proportion of the cases recovered speedily, but if this did not take place soon; the duration might be prolonged for weeks or even months. The albuminuria often became intermittent before it ceased altogether. Relapse was not uncommon. Some, no doubt, were becoming chronic nephritics, but the immediate mortality was very low.

He gave reasons for believing that the epidemic was due to a specific infection, probably resembling, but not identical with, the organism causing scarlet fever. He thought that animal inoculation experiments with material from recent cases were advisable, and suggested that much might be learned as to the mode of infection by the preparation of maps showing the exact distribution of the cases.

DR. GEORGE ALLAN HERON, formerly of Harley Street, W., left £1,007.

DR. J. J. O'SULLIVAN has been elected Mayor of Waterford. He has been Alderman and High Sheriff of the city.

MISS ELLEN PEARCE, of Southsea, has left £500 each to Dr. Barnardo's Homes, the Royal Portsmouth Hospital, and the Portsmouth Victoria Association for Nursing the Sick Poor.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

SECURITY OF TENURE FOR HEALTH OFFICERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the excellent paragraphs in which you refer to the decision of the Government to make the tenure of office of M.O.H. permanent, you modestly refrain from taking any credit for what your excellent paper has done to promote this reform. During the twenty years in which I have known the MEDICAL PRESS AND CIRCULAR you have persistently exposed the weakness of the M.O.H.'s position. It is certain that Mr. John Burns, the late President of the L.G.B., was fully informed of the views of the medical world; his utterances constantly showed that he got his knowledge from medical papers direct. It was he—the most able President of the L.G.B. of my time—who paved the way to the proposed reform which his accomplished successor, Mr. Long, is now about to complete. Permanency of tenure for the M.O.H. is most urgently called for in the smaller urban districts of which the population varies between 20,000 and 100,000. At present under county councils and in our great towns with populations of 500,000 to 1,000,000 or more, the Medical Officer's position leaves little to be desired. County councils and the councils of great towns always contain a strong minority if not an actual majority of men of education and some statesman-like qualities. Enough men of this character and with public spirit enough to render them willing to make the personal sacrifice involved—the work never gains either honour or fame—are always to be found in a large community. In our smaller towns it too often happens that the majority of citizens cannot be induced to take any real interest in local affairs. They will not come forward themselves, nor will they take any part in encouraging and supporting suitable candidates for a place on the local authority. Thus it commonly happens that a town council is composed of much too largely, if not dominated by, ignorant, mean and vulgar men, many of whom have sought office merely to guard their own sordid interests as owners of insanitary dwellings and slum property. To give the M.O.H. permanency of tenure under such bodies will be of some advantage to him, but will not entirely guard him against bullying and persecution which it will take much strength of character to withstand. I quite agree that it would be an enormous advantage to the nation if the sanitary administration were directed by a Minister of Health and worked by a body of medical civil servants. But it must be borne in mind that this would be quite contrary to what are called the democratic principles of the day. We seem pledged to the idea of Government “of the people, by the people, for the people.” We are more and more democratising all our institutions; but it is evident that democratic institutions cannot be properly constituted nor carried on efficiently unless every decent citizen will take his share in establishing them and in forming a body of public opinion which they must regard. In this country our public bodies are, I am convinced, entirely free from the corruption which marks similar bodies in some of the states of America, but we suffer here from inefficiency and mal-administration enough to clog the wheels of social progress. The hope has been

expressed in your columns lately by more than one writer that the cleansing fires through which our nation is now passing will, after the war, find us a people, with conscience aroused to the claims of public service and self-sacrifice for the advantage of our fellow-countrymen. If this hope be realised and a true democracy be evolved, there will be no need to safeguard the M.O.H. in the performance of duties, the value of which will be universally understood. This letter would gain no strength from addition of my name, and for several reasons, which I am sure you will appreciate, I beg to be allowed to subscribe myself as on previous occasions.

Yours truly,

AN URBAN M.O.H.

February 17th, 1916.

MIDDLE EAR DISEASE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—On January 26th last you published a very interesting letter from Dr. Frank E. Miller, of New York, on "A simple method of aborting middle ear inflammation and infection leading to mastoid trouble." I would like to say that I thoroughly support his opinion, and have long contended that if the general practitioner were to study his ear work better before entering general practice he would be able to avert many of the more serious ear troubles. Having all my professional life taken a special interest in the subject, I am in a position to state that I have never during the last twenty-five years had a case of acute aural inflammation drift into mastoid trouble, not even perforation, in cases in which I have been called in early when the patient is suffering from pain.

All ear cases, in my experience, can thus be prevented from drifting into the more serious state if treated sufficiently early by a competent medical man.

I think, however, that Dr. Frank Miller seems to imply that all cases of myringitis would drift into this state if not so treated. Personally my own experience has taught me to regard these cases of myringitis, which have their origin from within, namely, which are an extension of inflammation of the middle ear, caused generally by eustachian obstruction, as being much more serious than those that commence on the external ear side and which are best treated as Dr. Miller states.

If, however, the trouble is due to eustachian obstruction, as evidenced not only by redness and inflammation of the tympanum, but also by a bulging of the membrane as shown, by the dulness of the membrane and by its convex instead of concave appearance, then the only proper treatment is to incise the drum.

I am accustomed to make this incision at the posterior half of the membrane, and to extend the incision as low down as possible so as to get a free drainage. In one case, the daughter of an M.P., whom I was called in to see in my general practice suffered from intense ear-ache. On examination, I found that the drum had perforated quite recently at the upper anterior third of the membrane. I at once advised that an incision should be made into the drum. The opening being too small to drain, and in a bad position, I had to make a circular incision, backwards and downwards, thus involving an incision nearly two-thirds of the drum in extent. For some time I was very anxious that the wounded membrane would not heal, but my courage was rewarded, for in three weeks the drum was quite healed and the patient returned

home with practically a perfect drum and perfect hearing.

Another case was a boy who came to me only the other day with a profuse discharge from both ears. I quite thought that both drums must be perforated. I cleaned out the ears and blew in a little protalgin powder and boracic powder, and in three days' time the ears were practically free from discharge, although the drums were very congested. If the external inflammation of the ear had not been treated, no doubt the inflammation might have spread through the drum to the middle ear, but the inflammation does not easily go through the tough membrane in these cases.

A third kind of inflammation that I have seen is that which commences in the middle of the three membranes of the tympanum—viz., in the fibrous portion. I remember seeing a case of a boy from France who had been attended by some French doctors for a little ear trouble; whether he had it then, I don't know, but when I saw him he had myringitis with a small polypus growing from the head of the malleus. Removal of the polypus at once stopped the inflammation of the neighbouring tympanic region.

Unless some differential diagnosis is made as to the origin of the myringitis I cannot but feel that the patient runs a risk of having mastoiditis, in spite of the palliative local treatment only.

I am, Sir, yours truly,

W. T. GARDNER, M.B.LOND.

Bournemouth.

INFANTILE MORTALITY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Writing of the high mortality among the male babies, you say, this week, that the most obvious theory explaining it is "that boys, being much more highly organised than girls, succumb much more readily to unfavourable environment." Certainly the genital eminence and ridges and folds reach a farther stage of development in the male than in the female, and the testes descend farther than the ovaries. But, apart from these details, does organisation advance any farther in the male than in the female? I think not; and, in my opinion, the difference between the sexes in the resistance they offer to the environment is physiological rather than morphological. It may be expressed in the formula that in the female anabolism predominates over katabolism more than in the male. In other words, the female keeps a larger balance of protoplasm in the physiological bank than the male does all her life, and between puberty and the menopause she often has some to spare for investment (in the form of a baby) as well. She may eat less than the male, but her metabolic processes are less active, she breaks up less protoplasm and excretes less accordingly. Thus her physiological balance is more stable, and she resists the attacks of her environment more successfully than the male.

A girl comes to maturity quickly; after puberty she produces an excess of protoplasm above her own needs. This is expressed in the menstrual flow until pregnancy begins. Then the surplus goes to form the fetus. After labour it forms the milk supply until the next pregnancy begins. So it goes on until the menopause, after which there is often enough to form a good deal of fat. And then she lives far longer than a man, as any insurance office can tell!

Women are really much more resistant than men. They tolerate indoor life and prolonged work much

better than men. They recover from disease, injury and surgical interference much better. Nothing that we can do will make male infants as difficult to kill as female infants. Also the males have larger heads and thus get more injured during birth than their sisters. However, unfavourable environment increases the proportion of male births. So that if the war goes on long enough to cause actual privation the balance between the sexes may be more or less restored. I am enjoying your "sinapisms" every week; they are most refreshing.

I am, Sir, yours truly,
W. E. FOTHERGILL.

337 Oxford Road, Manchester.
February 19th, 1916.

TESTIMONIAL TO DR. J. POWER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Now that the question of certification under the National Health Insurance Act has been settled, we desire to bring to your notice a proposal which was adopted at a meeting of the Medical Profession held recently in Waterford, namely to inaugurate a testimonial to Dr. J. Power, Ardlinnan, in recognition of his valuable and well-known services in connection with the above settlement.

A Provisional Committee was appointed for this purpose, and it was suggested that subscriptions be limited to £1 1s.

The Committee trust that you will promptly respond to their appeal, and give the movement your earnest support.

Dr. Jellett, 11 Beresford Street, Waterford, has kindly consented to receive subscriptions, which should be forwarded without delay as the Fund will be closed on March 17th next.

Signed on behalf of the Provisional Committee,
P. STEPHENSON.

Hon. Secretary.

Carrick-on-Suir.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN
IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, DECEMBER 17TH, 1915.

The President, GIBBON FITZGIBBON, M.D., in the
Chair.

PUS TUBES REMOVED FOR THE CURE OF STERILITY.

DR. HASTINGS TWEEDY showed a case of above where he had resected both tubes and inserted a piece of No. 1 chromicised catgut in the lumen.

Sir WILLIAM SMYLY said the tubes appeared to be tuberculous. If that were so it showed that pelvic tuberculosis was a very localised and chronic condition.

DR. SHEILL suggested a further improvement in *technique* by passing a double thread of fine catgut through the tube by means of a forked probe, splitting the stump of the tube and suturing each flap together with one of the ends of gut to each side of the ovary so as to embrace it. He considered a false passage made in passing the gut as of little importance.

DR. GIBBON asked how Dr. Tweedy knew that the catgut lay in the lumen of the interstitial portion of the tube. His difficulty in these cases was to get the chromicised catgut to pass along through

the lumen of the tube without making a false passage, and this was particularly so when it reached the interstitial portion. He had bisected the uterus after passing the catgut, and even then he could not be sure that the catgut was in the lumen.

INFANTILE TETANY.

DR. SPENCER SHEILL read a paper on the above subject.

DR. ELLA WEBB said that care should be taken to define tetany definitely, as Dr. Sheill's cases appeared to resemble convulsions from causes either of a toxic or irritative nature. The question was whether cases with the following symptoms could be named tetany:—Slight tonic spasm, with occasional spasm such as flexion of the forearm or thigh, the movements in the latter being increased by pressure. It seemed as if tetany, as described in the text-books, took an intermediate place between definite convulsions and these slight spasmodic contractions.

DR. SHEILL, in reply, defined tetany as spasms of face and limbs without loss of consciousness. He considered tetany to be a mere symptom of some ailment, and to be a stage less than true convulsion and a stage worse than simple spasms.

THE ORIGIN AND BOUNDARIES OF THE LOWER UTERINE SEGMENT.

DR. HASTINGS TWEEDY read a paper on the above subject. He claimed that there was now sufficient data available to clear up the mystery in connection with this anatomical structure. The endoperitoneal tissue formed the true boundary between the cervix and body and constituted the tendinous extremities of the uterine fibres. Until this tissue had been put out of action either by rupture or by opening of the os internum there could be no pressure exerted on the cervix. He showed that the dilatation of the internal os was an early phenomenon of pregnancy, and that this dilatation permitted the ovum to pass through and press directly on the cervix. Continuous pressure on the cervix caused a rapid hypertrophy, and this law obtained in the unimpregnated as well as in the pregnant uterus. The cervix did not stretch, but grew, and the growth of the lower uterine segment had its complete counterpart in the growth of the supravaginal portion of the non-pregnant "prolapsed uteri."

Sir WILLIAM SMYLY said that most of the ideas in the paper were new to him, and he could not immediately make up his mind as to how far they would conform to the established facts, though, to a large extent, they appeared to do so. As regarded the origin of the lower uterine segment the communication left the arguments depending on the histology of that part unaffected.

DR. ASHIE said that the opening of the pelvic fascia was more rigid than was usually imagined. The uterus fitted into this as a hanging hinge. The elongation of the cervix in cases of prolapse was due to a piping of the uterus, which was driven down, whilst at the same time the cervix elongated.

DR. KIDD said he would wish Dr. Tweedy to reconcile one or two practical points with his theory. Firstly—In cases of elderly primiparæ, if hypertrophy of the cervical zone took place instead of elastic distension, why was there more tedious dilatation in elderly primiparæ than in young primiparæ? Secondly—In cases of "rigid os," where the cervical zone was so thinned out that it was very difficult to say the position of the os, how could he reconcile that with hypertrophy of cervical zone? Thirdly—When premature rupture of membrane occurred labour would be prolonged in first stage because the "hydrostatic dilation"

was lost. Did not that circumstance point rather to an elastic distension than a hypertrophy?

Dr. SHEILL considered the theory advanced to be very ingenious, but queried if this growth, due to sustained pressure, could account for hypertrophied cervix in virgins following increased abdominal pressure from tight lacing and constipation.

Dr. GIBSON said the supra-vaginal portion of the cervix adapted itself to pregnancy just as the body did. The growth of the cervix began, however, long before labour commenced. I could be recognised after artificial dilatation of the cervix during the seventh month.

The PRESIDENT said that the original controversy over Bandl's and Müller's rings was left in an undecided position, and was still undecided. Dr. Tweedy supported Bandl's view, and the explanation which he offered for the formation of the lower uterine segment out of the upper dilated portion of the cervix seemed very plausible and to be what was required to give preponderance to the one theory over the other. He (the President) concurred with Dr. Tweedy in his view of the structures.

Dr. TWEEDY replied.

NEW LONDON DERMATOLOGICAL SOCIETY.

MEETING HELD FEBRUARY 10TH, 1916.

DR. ALFRED EDDOWES in the Chair.

CASES.

Dr. SAMUEL: A case for diagnosis. A middle-aged woman having an ulcerating lesion under the right eye suggesting a breaking-down rodent ulcer, a number of so-called sebaceous senile warts, and some lesions looking like developing rodent ulcers; on the back one pigmented pedunculated lesion. The question arose whether it was a case of multiple rodent ulcers or epithelioma adenoides cysticum.

Dr. VINRACE suggested that if one noted the transitional stages the condition could be followed from its earliest inception to the development of the largest mole. He thought the lesion specially referred to had undergone some change due to traumatism; possibly the lancet which the patient said had been used. He recalled a case of generalised psoriasis which he showed at the last meeting, in which, beneath the clavicle, there was a patch which looked like epithelioma. Since he showed the case, that had healed, and left a sound surface. He thought that this would heal, too.

Dr. SEQUEIRA said the tumours were multiform in character and that the lesion below the right eyelid was rodent ulcer; it had the typical edge.

The PRESIDENT regarded the case as very interesting because it exhibited a number of epithelial lesions of seborrhœic origin behaving differently according to site. The one on the face resembled rodent ulcer; it was on a common site for that condition. He had investigated a case of epithelioma adenoides cysticum, of which he showed a section and drawings at the British Medical Association meeting at Oxford. There was a marked difference between that case and rodent ulcer.

Dr. SAMUEL replied that the great characteristic of epithelioma adenoides cysticum was the multiplicity of the lesions, which, clinically, almost exactly resembled rodent ulcer. It was exceptional for rodent ulcer to be multiple, and the other disease did not spread and recur, and might exist for years without ulcerating. It was early yet to say whether there would be ulceration in this case. The lesion under the eye certainly seemed to be rodent ulcer.

Dr. EDDOWES: (1) A young woman with an

extraordinary degree of redness and slight swelling of the face over the area usually affected with rosacea. On the forearms were some erythematous patches with central nodules. She stated that a few days ago her face was so swollen that she could not see out of her eyes.

Dr. SEQUEIRA thought the case was one of erythematous eczema of the face. When eczema attacked the face and the leg it often assumed a ruby-red aspect, and this patient's swelling of the eyelids he regarded as very characteristic of that condition.

Dr. SAMUEL said one could not quarrel with the diagnosis of erythematous eczema. He considered there was a big dyspeptic element in the case. It was, in his view, the rosacea type of dermatitis.

Dr. VINRACE considered that the skin condition was due to deficiency of circulation, and tending ultimately to lupus erythematosus.

The PRESIDENT (Dr. Eddowes) regarded all the remarks which had been made on the case as valuable. The nodules on the arms were important, but there was no tubercular history in her case. She might develop lupus erythematosus, which sometimes was ushered in in this violent way.

Dr. SAMUEL: Case of mycosis fungoides. The patient, a middle-aged man, has had the condition 18 years, and has been to a number of hospitals with it. It started in a pre-mycotic eczematous stage, and several pre-mycotic tumours have been removed by X-rays, but the rays did not stop the tumours coming out elsewhere. He has been a widower four years, and has two healthy children; both they and his late wife having had apparently healthy skin. At one hospital his lesions were treated with the actual cautery.

Dr. MACK thought the use of the X-rays had prolonged the patient's life.

Dr. SEQUEIRA said there were cases on record in which the tumours had undoubtedly cleared up under the influence of X-rays.

Dr. VINRACE remarked that a noteworthy point was the rapid development during the last four years.

Dr. SAMUEL replied that X-rays had been applied during the last fourteen years to different parts of his body.

Dr. VINRACE: Case of epithelial growth on the nose. The patient, a man over 80 years of age, has had an almost stationary epithelial growth on the nose fifteen years. A crust of *débris* gradually formed, and when removed from time to time left a slightly bleeding surface.

Dr. SAMUEL thought the lesion was probably a rodent ulcer, judging by the history of commencement, and what happened when the crust was removed. He suggested freezing with CO₂ snow.

The PRESIDENT said the lesion seemed superficial and crusted, like a chronic folliculitis.

Dr. SEQUEIRA recommended the simple application of acid nitrate of mercury.

Dr. MACK said the case was almost like one he showed of lesion of the forehead of seventeen years' duration, which crusted in the same way. On removing the crust it left a slightly ulcerated surface.

Dr. VINRACE replied that he had regarded it as a very slow-growing epithelioma.

Dr. EDDOWES: (2) Purpura (peliosis) rheumatica in a young girl. The eruption, consisting of patches varying in size from that of a pea to that of a shilling, covered both legs, was plentiful on trunk, and even a few showed on the face. The usual pains were complained of in legs. The patient has been very subject to "colds" in the throat; tonsils have been surgically treated, but are still ragged and catarrhal. Dr. Eddowes believed they were

the chief source of toxin in this case, and advised their early enucleation. He added that on the previous day the rash was very extensive, and most of the patches were dark, but they had since become much paler, the mouth was cleaner, and the tonsils showed improvement under treatment. He only saw the case yesterday for the first time. The patient had been confined to bed, and was reported to have been feverish, and to have had much pain in the legs.

Dr. SAMUEL agreed it was purpura, but thought it did not agree with the description of peliosis rheumatica.

Dr. SEQUEIRA regarded the case as a typical one of peliosis rheumatica; the history pointed to it, and, in his experience, the eruption in that condition was not, as Dr. Samuel had said, confined to the joints; if it occurred in the leg it was distributed all down the leg.

Mr. VINRACE asked what were the evidences of acute rheumatism in this case.

Dr. MACK thought this would prove to be a toxic purpura. He thought there were symptoms in this case which could be referred to rheumatism.

Dr. EDDOWES replied that when seen the previous day the patient still looked ill and complained of pains in the limbs. Patients with catarrhal tonsils frequently complained of pain in the limbs, and it was reasonable to regard the condition in this case as starting in the tonsils. He thought Dr. Samuel took a certain text-book view; but many authorities had a wider conception. Rashes did not follow hard and fast lines—for example, fatal scarlet fever could occur without rash. He saw a little girl during the last epidemic of small-pox who had purpura in the groin, but the child looked remarkably well, and had probably picked up some ptomaine poison. Somebody who differed from him sent the case to a small-pox hospital, but it was returned in 48 hours, well. There the effect of the "toxin" (ptomaine) was only temporary.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD FEBRUARY 3RD.

The President, DR. EDMUND CAUTLEY, in the Chair.

An interesting selection of cases were shown and demonstrated by Drs. LEONARD GUTHRIE and FEARNSIDES.

(1) A soldier with cauda equina lesion due to shrapnel wound, having complete loss of power in left and paresis of right leg; the chief feature of the case being attacks of intestinal obstruction and loss of control over bladder and rectum.

(2) Man, *æt.* 56, suffering from lesion of corpus striatum, the symptoms commencing with eccentricity and suicidal tendencies, and developing into dumbness and inability to move the limbs, which are the seat of contractures. The reflexes are present, he takes no notice of his surroundings, but has incontinence of urine and *fæces*.

(3 and 4) Soldiers with limitation of visual fields resulting from wound in parieto-occipital, and occipito-mastoid regions respectively.

(5) A case of *tabes dorsalis* with Charcot's knee-joint.

(6) A case of reflex spasticity following bullet wound near spine at level of 10th rib.

(7) Myopathy with contractures in a woman *æt.* 10.

(8) Mental amblyopia in a woman following insomnia, the optic discs being normal, but fields very contracted.

(9) A case of disseminated sclerosis sent in to the hospital as hysteria.

(10) A case of cervical amyotrophic lateral sclerosis in a female *æt.* 50.

(11) Case of optic neuritis probably due to cerebral tumour.

The PRESIDENT and Dr. WILFRID DAVSON also showed a case of considerable fatty enlargement of the legs and arms in a young woman, the feet, hands, and the rest of the body being unaffected.

OBITUARY.

DR. R. G. ALEXANDER, M.A., M.D., J.P.,
HALIFAX.

THE death of Dr. Reginald G. Alexander, M.A., M.D., J.P., will leave a notable gap in Halifax circles—medical, social, literary and philanthropic. He was the descendant of a family which has been prominent in the annals of Halifax for a couple of centuries past. During that time the heads of the family have been actively identified with the medical profession, his father (Dr. William Alexander), his grandfather (Dr. Gervase Alexander), and his great-grandfather (Dr. Robert Alexander), all practising in the town in their day. The family's long and honourable association with medicine is continued in the person of the deceased's eldest son, Dr. Gervase Alexander, who pursues his calling at Bodmin, in Cornwall.

Dr. Alexander was educated at Shrewsbury and Cambridge. He graduated M.A. Cantab. in 1874. He received his medical training at Cambridge, King's College, London, and Edinburgh, taking the M.B., C.M. Edin. in 1871, and M.D. in 1881. He was also a Fellow of the Linnean Society. He was a county magistrate, and in the year 1885-6 he was chosen by his medical colleagues for the position of President of the Yorkshire Branch of the British Medical Association, while he also held the position of Consulting Physician to the Lords of the Admiralty for Yorkshire. His connection with the Royal Halifax Infirmary as a member of the hon. medical staff extended from 1886 to 1912, and the family's keen interest in this local institution is indicated by the fact that father and son between them gave their services over the long and unbroken period of 72 years. The deceased also held a similar position at the Royal Infirmary, Bradford, from 1886 to 1912. He was one of the claimants in a recent peerage case, and was declared co-heir of the baronies of De Burgh, Cobham and Strabolgi. The late Dr. Alexander died at the age of 68 years, and the end came quite suddenly from heart failure. He leaves two sons and two daughters.

DR. J. F. STURROCK, M.B., C.M., J.P.,
BROUGHTY FERRY.

THE death occurred on February 13th, at Broughty Ferry, of Dr. J. F. Sturrock, a well-known local practitioner, after a somewhat protracted illness. He was a native of Montrose, and graduated M.B., C.M. in 1885, at Edinburgh University. He went to Broughty Ferry about thirty years ago. When Broughty Ferry was a separate burgh, Dr. Sturrock was Medical Officer of Health, and he otherwise interested himself in public affairs, being a member of the School Board for several years and Chairman for a term.

DR. C. LAKIN, L.R.C.P., L.S.A., J.P.,
LEICESTER.

THE death has occurred of Dr. Charles Lakin, of London Road, Leicester.

Dr. Lakin underwent an operation for a serious internal malady, and after lingering for eight days, died on February 10th. He was sixty-seven years of age.

Dr. Lakin was not only one of Leicester's best-known medical practitioners, but was also one of its most noted public men. In 1835 he was elected a member of the Leicester Town Council. He retained membership of the Council until his death, and in 1892 his

zealous work was rewarded by his elevation to the aldermanic seats. In 1908 Alderman Lakin reached what is recognised as the zenith of a municipal career, when he filled the office of Mayor, a post which, with the aid of Mrs. Lakin, he filled with a dignity which stamped his year of office a most successful one. Dr. Lakin received his medical training at Queen's College, Birmingham, qualifying L.R.C.P. Edin. in 1872. In 1899 he published a work on "Some Medicinal Plants of Leicestershire."

**SURGEON MAJOR-GENERAL PINKERTON,
M.D., F.R.C.S., GLASGOW.**

THE death is announced at Glasgow of Surgeon Major-General John Pinkerton, a retired officer of the Indian Medical Service and Honorary Physician to the King. General Pinkerton, who was in his eighty-fourth year, graduated M.D. at Glasgow University in 1855, and immediately afterwards entered the Indian Medical Service, in which he remained until his retirement in 1893. During his stay in the East he held a number of important appointments, and was with the forces in the Persian War. After his long career in the Army he returned to Glasgow, where he took little part in public affairs, although showing an interest in matters connected with the University.

**SURGEON-COLONEL E. A. GIBBON, HIGH
SHERIFF OF CO. WEXFORD.**

WE regret to note the sudden death of Surgeon-Colonel Edward Acton Gibbon, which occurred at his residence, Sleadagh, Co. Wexford, on the morning of the 15th inst., at the age of 82 years. Colonel Gibbon obtained his qualifications from the Royal Colleges of Ireland as long ago as 1860. He spent twenty years in the Army Medical Service, many of which were spent in India. He retired in 1881, and settled to the life of a country gentleman in County Wexford. He was active in local public affairs, and was a magistrate for the county. He was serving in the office of High Sheriff in the present year. He leaves three sons, two of whom are serving in the Royal Army Medical Corps.

**DR. G. H. CHARLESWORTH, M.D., M.R.C.S.,
L.R.C.P., D.P.H., PUTNEY.**

DR. GEORGE HENRY CHARLESWORTH died on February 8th at the age of 56, at his residence, White Lodge, Upper Richmond Road, S.W. Receiving his medical training at Charing Cross and King's College, he qualified M.R.C.S. Eng. in 1886 and L.R.C.P. in 1887. He graduated M.D. (Brux.) with distinction in 1889, and took the D.P.H., R.C.P.S. Lond. in 1893. He was for many years district medical officer to the London County Council, hon. medical officer to the Actors' and Music-hall Artists' Associations, and medical referee to several prominent insurance companies. He was late hon. consulting medical officer, resident medical officer and assistant medical officer to the Wandsworth Provident District, and assistant demonstrator in practical chemistry and pathological assistant to the Charing Cross Medical School.

Dr. Charlesworth was well known throughout his profession, and was held in the highest regard by his very large circle of acquaintances and friends. He was exceedingly popular, both as a doctor and as a magistrate on the bench, and his early death is deeply regretted by his friends, patients and colleagues.

**DR. NATHANIEL E. ROBERTS, M.B., C.M.,
D.P.H., LIVERPOOL.**

DR. NATHANIEL ROBERTS died on February 19th at Menai Bidge. Deceased had an interesting career. In his youth he was employed as a pork butcher at Bangor. By industry and perseverance he qualified as a chemist and later proceeded to Edinburgh to prosecute study in medicine. He qualified M.B., C.M. in 1879, and 1892 took the D.P.H. of the Edinburgh Colleges. Settling in Liverpool, he became Medical Officer of the Toxteth Park Union. He later was

Visiting Physician to Grafton Street and Park Hill City Hospitals and Assistant Medical Officer of the Port of Liverpool. He was also Lecturer on Infectious Diseases and Vaccination at Liverpool University. He held the rank of Lieutenant-Colonel, R.A.M.C. (T.F.).

SPECIAL REPORTS.

MORE DOCTORS FOR WAR WORK.

THE following circular letter has been issued by the Local Government Board to County Councils, Metropolitan Borough Councils, Sanitary Authorities (including port sanitary authorities), Joint Hospital Boards and Committees, and Joint Committees for Appointing Medical Officers of Health:—

"I am directed by the Local Government to state that it has become necessary to make provisional arrangements for enabling every medical man of suitable age (45 and under) who can be spared from civil employment without serious injury to the civil population, to place himself at the disposal of the authorities, and to be prepared, if required, to take a commission in the Army or Navy in the near future. A representative committee of the medical profession, known as the Central Medical War Committee, has been formed to facilitate the carrying out of this object. This Committee has asked the Board to supply them with a list of doctors of military age who are engaged in public health work of local authorities, classified as follows:— (1) Those who could be spared almost at once; (2) those who might be spared later; (3) those who cannot be spared. To enable the Board to comply with this request they will be glad if the authority will take the matter into their immediate consideration and supply the Board with the information indicated on the enclosed form.

"The authority, in considering the matter, must bear in mind the special importance of maintaining the public health at the present time, but, subject to this, they should be prepared to allow medical men of military age who are in their service to join the forces. In some areas a reduction of staff may be rendered feasible by co-operation between the county and district authorities, or between neighbouring authorities. I am to add that by arrangement with the War Office applications for commissions from medical officers of public health authorities are referred to the Board for their concurrence or otherwise, and in view of this arrangement the Board think that all such medical officers may properly enrol themselves under the scheme of the Central War Committee."

FOR damage to the Royal Pavilion estate while a hospital for Indian troops Brighton has received £4,077.

DOLLIS Hill House, Willesden, where Gladstone stayed frequently when Prime Minister, has been opened as a military hospital.

THE Lord Mayor, who was accompanied by the Lady Mayoress and the Sheriffs, opened on February 7th a war hospital supply depot at Muswell Hill.

MR. LAWRENCE READ, formerly of 18 Hanover Square, W., dental surgeon, left £1,000 to the Benevolent Fund of the British Dental Association.

THE Duke of Connaught, on behalf of the British Red Cross, has accepted an ambulance presented by the British Empire Association of the State of Illinois.

A NEW phthisis pavilion has been opened at the Mill Lane Hospital, Liscard. The new pavilion, with its spacious verandahs with a southern aspect, has sleeping accommodation for eleven male and eleven female patients. The total cost has been £2,300, towards which the Local Government Board has contributed half.

SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Mercurial Poisoning from a Vaginal Douche.—Fesckett (*Amer. Jnl. Obs.*, lxxii., 4) reports a case of acute poisoning and death from the use of a very strong solution of bichloride used as a vaginal douche, although pain was felt and treatment sought very soon. The case is instructive in showing the danger of advising patients to adopt methods of treatment without giving full instructions where there are dangerous poisons to be used. The physician who was consulted after the douche had been given apparently only ordered further treatment in the way of douching and ointments to be carried out by the patient on herself, as a result of which the initial poison was not removed. This goes to show the futility of self-administered vaginal douches for the purpose of removing discharge or other material from the vagina. F.

Prolapse of the Vagina, Traction Elongation of the Cervix, Prolapse of the Uterus, etc.—Keyes (*Amer. Jnl. Obs.*, lxxii., 4) says that the multiparous uterus is very prone to undergo some true traction elongation, without or with some prolapse of the corpus uteri. Vaginal traction on the cervix may cause either elongation or prolapse of the uterus. If the upper pelvic floor supports are normally strong it requires considerable vaginal traction to pull permanently down a uterus held in place by an intact and elastic periparametrium. The upper floor segment with the normal acute or right angle successfully hinders secondary prolapsus uteri, and vaginal traction, if present, may cause true traction elongation. The uterus, though retroverted, may still be held at the normal height by its own supports. Prolapsus uteri is divided into (1) primary nulliparous, (2) parous, (3) combined primary and secondary, (4) purely secondary in the parous. In the virginal and nulliparous primary prolapse the absence of cystocele and rectocele forces one to seek other causes—e.g., congenital periparametric weakness. In the primary parous prolapse the acquired upper floor segment weaknesses due to childbirth are the most important. An enlarged sub-involuted uterus of itself seems to have little influence in causing prolapse. Not the least among the causes of prolapse is the premature application of forceps and tearing of the para-uterine and para-vaginal tissues of the upper floor segment. In purely secondary prolapse the upper floor segment is at first normally resistant, and the descent may be very gradual, taking years to come down to an appreciable degree. Treatment is considered under prophylaxis in pregnancy and labour and by oblique episiotomy to save the lower pelvic floor segment. The true principle of operation is to reunite the recto-vesical fascia and levator muscles, and in anterior colporrhaphy the recto-vesical fascial supports of the bladder. The lower segment operations alone suffice in those cases in which the cervix is still maintained at its proper height. The vaginal interposition of Schauta is often placing too much reliance upon the anterior portions of the upper floor segment and recto-vesical fascia without sufficient regard to posterior portion. F.

Sodium Citrate for Direct Blood Transfusion.—Schildecker (*Amer. Jnl. Obs.*, lxxii., 5) describes a method and container for taking blood from the donor and preventing coagulation by the addition of sodium citrate. The method appears simple, and for it, it is claimed that the whole procedure is visible, no hurry is necessary, the exact quantity of blood taken is measured, it does not require much experience to use it, and it can be followed in a private house. F.

Nephrectomy during Pregnancy.—Schmidt (*Surg.*,

Gyn. and Obs., xxi., 6) records a case in which the patient was 6½ months pregnant at time of operation. The kidney had evidently ceased to function and was discharging pus only into the bladder. The immediate result was uneventful, and delivery occurred normally at term of a living child. Thirty-four other cases are collected and tabulated. The total mortality was two cases. Twenty-one cases were operated upon in the third, fourth and fifth months, and 77 per cent. had normal deliveries at term. The after-condition of only one kidney is not considered a bar to pregnancy, provided the one kidney is healthy and some time has elapsed since the nephrectomy without evidence of disease. F.

Hæmorrhage in Newly-Born Babies.—Manning (*Archives of Pediatrics*, November, 1915) records the cases of six babies who suffered from various forms of hæmorrhage shortly after birth. In five of the six cases blood was vomited and passed by stool, while in the other case the bleeding took place from the wound resulting from a circumcision. All the patients were treated with some form of blood serum. Horse serum, anti-streptococcal serum, and anti-diphtheria serum were used in various cases, and two patients were treated in addition with serum derived from their father's blood. Two of the six patients died, one of whom had an intracranial bleeding, and in the other numerous small echymotic spots were found along the course of the intestine, which, however, was not ulcerated. Cultures from the heart and umbilical vessel of this latter child showed a streptococcal infection. Manning concludes that blood serum therapy at present offers the best hope of success in the treatment of this distressing condition, but that there appears to be no reason why other forms of treatment should be entirely discarded. K.

Source of Error in the Use of Esbach's Albuminometer.—Jones (*Glasgow Med. Jnl.*, January, 1916) points out that urine that is strongly alkaline may fail to give a precipitate with Esbach's reagent even though the urine may contain large quantities of albumin. He records the instance of a urine which was strongly alkaline, and which, with various tests, showed that it contained a considerable quantity of albumin. Esbach's reagent and this urine, mixed in equal proportions, gave a cloudy precipitate, which disappeared on being shaken. On allowing this urine, mixed with the reagent, to stand in the albuminometer for twenty-four hours, no precipitate was produced. The mixture, which was already acid in reaction, was more highly acidulated with citric acid, and the result was a copious deposit of albumin, which, on standing for twenty-four hours, registered "S" on the measured glass. Jones concludes that this case demonstrates the importance in testing of being careful as to the reaction of urine, and of not trusting to a reagent such as Esbach's as being sufficient, at least in small quantity, to precipitate albumin. K.

Concussion Blindness.—Ormond (*Jnl. R.A.M.C.*, January, 1916) states that he has treated a number of patients suffering from this distressing condition by suggestion and in every case with marked success. He points out the importance of the early treatment of such patients, and that if this cannot be done their condition should not be prejudiced unfavourably by injudicious handling. The most resistant case that came under his care was that of a man who, as the result of an explosion, had remained unconscious for six days. On recovering consciousness he was blind, completely deaf, and unable to speak. He had been

told by an aurist that he would never regain his hearing, and concluded that the blindness would also be permanent. Under treatment his sight and speech have returned, and there is reason to expect that improvement in his hearing will not be long delayed. It is probable that the presence of sand or grit in the conjunctival sacs of some of these patients may have been the cause of the suggestion of blindness, but they were not present in all cases, and recovery took place without their being removed. When present they were all imbedded in the conjunctiva, and did not produce any irritative symptoms at the time the patients were under treatment. K.

Toxicity of Emetine.—Peyman (*Jnl. R.A.M.C.*, January, 1916) points out that medical officers treating patients with amebic dysentery by emetine would do well to remember that the drug is very costly; that if it is going to do good its beneficial action is generally quickly apparent; that it is useless, unwise and wasteful to subject patients to repeated, long continued courses of the drug; and that emetine may itself produce and keep up a certain degree of diarrhoea, and that it is important to distinguish this drug-produced diarrhoea from that caused by intestinal disease. K.

THE LATE PRINCIPAL SIR WILLIAM TURNER, K.C.B., M.B., F.R.S., EDINBURGH.

By the death of Sir William Turner, the University of Edinburgh—indeed, the academic world of Scotland—has sustained a loss it would be impossible to estimate. Though a native of England, he crossed the border in his twenty-second year, in 1854, and spent the rest of his life in Edinburgh, being successively student graduate, assistant professor, professor, and principal of the University. He was appointed assistant to the late Professor Goodie, and in a very short time made his mark as a painstaking and careful observer and a most lucid teacher. So well was his work in this capacity done that on Goodie's death the young assistant was appointed to the vacant post. This was in 1867. For thirty-six years he was chief of the Anatomical School of Edinburgh, and as a teacher of his subject was unequalled. In his practical work and investigations he had an infinite capacity for taking pains, and accuracy was his *Shekinah*. He possessed another attribute of genius—the power of attracting like-minded men to himself. Many of these men are now professors of anatomy—in fact, there are very few chairs of anatomy in the United Kingdom that are not occupied by Turner's men. Besides the work of the chair proper, he had to find scope for his administrative powers, which were of a high order. As representative for the University, then as Chairman of the General Medical Council, Dean of Medical Faculty in the University; President of the College of Surgeons, and in many other positions, he did splendid work for his University and his profession. He was knighted in 1886, and shortly afterwards received his K.C.B.

His writings were copious: on the anatomy and history of man and the lower animals; as editor of the works of Paget, Goodie and Robertson; as founder and editor of the *Journal of Anatomy and Physiology*. He had received almost all the possible academic honours that fall to the lot of one man.

Such a strong personality as Sir William Turner is a big asset to the university to which he happens to belong; fortunate indeed is the university that has such a man on its staff. Even in the early seventies, when the writer was an arts student in Edinburgh, Turner's name was well known to those who sat at the feet of Blackie, Tait or Masson, and rarely were interested in anything outside their own quadrangle. But Professor Turner was known to them as far passing the ordinary. He had a halo of bigness comparable to that surrounding the names of Lister and Kelvin. And at this time memories of him are stirred regarding this "burdly," strong, kindly man whose work is now done, and his method and whole-hearted earnestness are recalled all over the world—on all the shores of all the seven seas.

MEDICAL NEWS IN BRIEF.

Oxford University Finance.

THE Board of Finance of Oxford University, in a report to the Hebdomadal Council on the finances of the University in the years 1915 and 1916, state that the complete figures for the year 1915 show (including the accumulated deficits of previous years) a total deficit of £12,572. To meet the deficiency the University has at its disposal items of revenue amounting to £18,806, which it is proposed to carry to an Emergency Account. If these sums were transferred to the General Fund and applied to the extinction of the deficit, the Emergency Fund would begin the year 1916 with a credit balance of £6,233; and there would still remain to the credit of the Common University Fund a cash balance of £2,722, in addition to an investment of the nominal value of £3,519 in 4½ per cent. War Loan (1925-45). The financial position at the commencement of 1916 is, therefore, more favourable than was anticipated a year ago.

The estimate of revenue and expenditure of the University in 1916 prepared by the Curators of the Chest shows: Revenue, £29,881, as compared with £37,049, the actual revenue of 1915; expenditure, £44,078, as compared with £46,372, the actual expenditure of 1915. The apparent deficit for 1916 is, therefore, £14,197. Even on the most favourable view of the future it appears to the Board unlikely that the "emergency" revenue of the year will be sufficient to cover the deficit of £14,197. It is, of course, possible that the deficit might be met if the credit balance carried forward (£6,233), together with any "emergency" revenue realised during the year, were applied to the purpose. But in that case the University would have exhausted nearly the whole of its cash resources, and would probably find itself in a position of great difficulty in 1917 and subsequent years. The Board are most unwilling to suggest any policy which would involve the entire depletion of the cash resources of the University at the beginning of what they cannot but regard as a long period of financial stress; but they think that any final decision with regard to the policy of the future may safely be deferred for a few months.

A Decree will be proposed in Convocation to create an "Emergency Relief (General) Fund."

University Students and Military Service.

THE Vice-Chancellor of Oxford University has received from Major Slessor, Recruiting Officer for the Recruiting Area, the following War Office instructions: "The calling up of students who are attending examinations at a recognised University before March 31st, 1916, is to be postponed until after the examination, provided it is not later than March 31st, 1916."

Major Slessor adds that a certificate from the Head of the College—or Senior Tutor—that the undergraduate is attending an examination this term will be sufficient authority for the Recruiting Officer to withhold the notice paper calling him up till March 31st. It should be addressed to the Recruiting Officer, 47 High Street. A separate certificate is necessary for each case.

Manchester Infirmary.

THE war work of the Manchester Royal Infirmary was the subject of comment at the annual meeting of the trustees, held on February 11th.

Sir Edward Donner said the past year had made extraordinary demands upon the honorary staff. They had taken over 200 military patients in addition to all their ordinary care of the civil patients. The staff had risen to the occasion, and their duties had never been more efficiently performed.

Sir William Cobbett pointed out that 308 beds had been prepared for military patients, and they were providing 42 more, making a total of 350.

Dr. Brockbank said that, with very few necessary exceptions, all the honorary staff were engaged on some form of war service, in addition to their

infirmary work. Dr. Albert Ramsbotham, who had been "Somewhere in France" since the autumn of 1914, had been mentioned in dispatches. Two others of the honorary medical staff were going abroad with the 33rd Base Hospital, which was shortly to be mobilised, and whose medical staff would be drawn almost entirely from Manchester. Some of their salaried medical staff and many other medical men trained or once resident at the infirmary would go with that hospital.

Many of the salaried medical staff were also engaged in military work in addition to their infirmary duties. Several had been in foreign service, and a few in Gallipoli.

A Proud Record.—One old resident, Lieutenant Bearn, of the Black Watch, had received the D.S.O., and was one of the few officers left, he believed, of the original number. Another old resident, Lieutenant Bedale, was mentioned by Sir Ian Hamilton in dispatches for services in Gallipoli. Lieutenant C. B. Marshall was drowned in the *Royal Edward* when she was torpedoed in the Mediterranean.

Edinburgh and its Sanatoria.

RECENTLY the Scottish Local Authority approached the Edinburgh Corporation asking them to give definite information as to the amount of accommodation they had for the treatment of tuberculous patients, in order that they might communicate with other local authorities throughout the country, who had no such provision, with the view of their being admitted for treatment if there was accommodation, so that, at any rate during the war, there should be no building or more provision for this. The matter was considered by a sub-committee of the Public Health Committee, who recommended against any other patients from outside authorities being received into the Edinburgh sanatoria. At present, while there are some vacant places, the numbers are sufficient for the depleted staff and nurses to look after, and it would be impossible to deal with more unless the staffs were augmented. In the present state of the country this is felt to be impossible. At the full meeting of the Public Health Committee on February 15th this view was adopted.

Ontario Military Hospital.

ON February 16th, at Orpington, Kent, Mr. Bonar Law opened the Ontario Military Hospital which has been established there. The cost and equipment of the hospital have been borne by the people of Ontario, and it has been handed over to the Canadian Army Medical Corps for use as a general hospital on the understanding that it is not to be confined to Canadians alone, but is to be open to any wounded soldier of the British Empire. There is accommodation for 1,040 patients. The staff of officers and nurses will be brought from Ontario, and will consist of 36 medical officers, 73 nurses, and 192 others.

Colonel the Hon. R. A. Pyne, who presided at the ceremony, explained that last year the Parliament of Ontario levied an assessment on the people of the province of an equivalent of about one farthing in the pound, which produced £400,000. With this it was decided to build a hospital in England of easy access to wounded soldiers. It was intended for the soldiers of the King, and to it any wounded soldier, be he black or white, would be welcome.

Health of Exeter.

THE Medical Officer of Health for Exeter, Dr. P. H. Stirk, in his annual report for 1914, states that the number of births registered in Exeter in 1914 was 1,193 divided as follows: 587 males and 606 females. Of this number 42 males and 35 females were illegitimate. The birth-rate was 19.76 per 1,000, being .33 higher than that of the year 1913, 4.04 below that of England and Wales, and 5.24 below that of the 97 great towns in which Exeter is classed. The corrected death-rate for England and Wales for 1914 was 13.7 per 1,000; for the 97 large towns in which Exeter is classed, 15.0; and for London, 14.4. The rate for Exeter was 12.52. The infant mortality in Exeter was 84.73 per 1,000 births, the lowest on record. The early notification

of births, the advice given to parents by the Health Visitor, and the work done by the Baby's Welcome Club were the contributing features for this result. Incidentally the Medical Officer mentions that mortality among hand-fed infants is five times higher than among breast-fed infants.

The death-rate in Exeter from the seven common diseases—enteric, small-pox, measles, scarlet fever, whooping cough, diphtheria, and diarrhoea—(under two years of age) was .597 per 1,000. No case of small-pox occurred in Exeter in 1914.

A Nova Scotia Hospital.

THE University of St. Francis Xavier, Antigonish, Nova Scotia, has offered a hospital unit to the British War Office for service at the front. The unit, which will be under the command of Captain McLeod, C.A.M.C., will consist of 12 doctors, 35 nurses, and about 125 attendants. This will be the second hospital unit provided by the Province.

Sheffield's Health Bill for 1914.

THE report of the Medical Officer of Health for the city of Sheffield (Dr. H. Scurfield), on the work of his department for the year 1914, has just been issued. It is dated September last, but publication has been delayed by pressure of work at the printers.

Summarising the principal features of the public health statistics of the year 1914, as compared with those of the previous decade, Dr. Scurfield states:—It was a heavy year for measles and whooping cough and it was an average year for scarlet fever, diphtheria, enteric fever, and diarrhoea. When we turn to other diseases there was an excessive number of deaths from cancer, an average number of deaths from tuberculosis of the lung and other tuberculous diseases, an average number from respiratory diseases, the somewhat low figure for bronchitis being balanced by a somewhat high figure for pneumonia. The number of deaths from cancer is, generally, appreciably below the English figure, but during 1914 the rate was quite up to the English figure for the last decade."

The mean estimated population for the year was 476,971. The number of births during the year was 13,004, which was less than in the previous year by 284. This figure gives a birth-rate of 27.3 per 1,000 persons living. This birth-rate is the lowest ever recorded, being 0.9 per 1,000 lower than that for the previous year, and 2.8 lower than the average for the last decade.

The number of deaths during the year was 7,790. This gives a death-rate of 16.3 per 1,000 persons living, which is the highest since 1908, and has to be compared with 15.8 for the previous year and an average of 16.3 for the decade 1904-13. The unfavourable comparison with 1913 is due to the fact that while the death-rate from whooping cough was higher by 0.35 per 1,000 in 1914, there was no diminution in the death-rate from measles as compared with the previous year.

Of the seventeen largest towns of Great Britain, six had higher birth-rates than Sheffield, ten had lower death-rates, and eleven had lower infant mortality rates.

American College of Surgeons.

DR. J. G. BOWMAN, of Chicago, Director of the American College of Surgeons, is reported to have stated recently that the college has obtained from its Fellows an endowment fund of £100,000, to be held in perpetuity, the income of which only is to be used in advancing the purposes of the college. The college has been in process of formation for the last three years. It has a temporary office in Chicago, and it is probable that permanent headquarters will be decided upon within a few days. The President is Professor J. M. T. Finney, head of the surgical clinic of Johns Hopkins Hospital, Baltimore. The college is modelled after the Royal College of Surgeons of England, and has the support, it is said, of nearly all the leading surgeons in the United States and Canada. The college, which is not a teaching institution, but

rather a society or a college in the original sense, now numbers about 3,400 Fellows in Canada and in the United States.

National Health Insurance.

NATIONAL Health Insurance Fund accounts just published show that in the period from July 15th, 1912, to January 11th, 1914, the receipts amounted to £33,391,218. The greater part of this sum represents sales of insurance stamps, the other principal item being the State contributions, totalling £5,748,150. The receipts for each of the four countries and the apportionment of the Exchequer grants are shown below:—

	Total receipts.	State grants.
England	£26,642,469	£4,532,089
Wales	1,740,959	293,814
Scotland	3,687,577	651,148
Ireland	1,320,213	271,099

Totals ... £33,391,218 ... £5,748,150

The four Commissions paid £11,280,540 to approved societies for sickness and maternity benefits and administration expenses; £5,554,187 to Insurance Committees for benefits and administration expenses; and handed £15,313,470 to the National Debt Commissioners and £901,423 to approved societies for investment.

Prussic Acid Shells.

THE *Bourse Gazette* says that it is reported from Dvinsk that an examination of the enemy's shells proves that their cast-iron heads are grooved, and that even four or five hours after they have exploded they emit a strong odour of prussic acid. These shells explode only on striking the ground: gases permeated with prussic acid poison the Russian soldiers in the vicinity, and the men who are wounded by fragments of shell die quickly, even though their injuries may be slight.

Medical Men in Austro-Hungary.

THE shortage of doctors at the front is being remedied by the calling up of all medical men capable of military service. An order just issued by the military authorities calls up all medical men for medical examination, even the heads of hospitals or assistants in military hospitals, but who are of civil status. It is explained that all the military and civil hospitals will have to be given into the charge of such physicians as are unfit for service at the front. In the hospitals, also, such medical students and physicians will be employed as have already served at the front, but who have been discharged from military service owing to illness or wounds.

Royal College of Surgeons of England.

THREE Artis and Gale lectures on "The Influence of the Arboreal Habit in the Evolution of Man," will be delivered in the Theatre of the College, by Frederic Wood Jones, D.Sc., M.B., B.S., M.R.C.S., on Monday, February 28th, Wednesday, March 1st, and Friday March 3rd, at 5 o'clock p.m.

Two Hunterian lectures on "Links in a Chain of Research on Syphilis," will be delivered in the Theatre of the College, by Professor J. E. R. McDonagh, F.R.C.S., on Monday, March 6th, and Wednesday, March 8th, at 5 o'clock p.m.

Doctors' Certificates.

A POINT as to the doctors' certificates provided for in the regulations of the Liquor Control Board in order to obtain spirits as medicine during prohibited hours has been raised in a case heard at Workington, where Hugh M'Mullen was fined 20s. and costs and Elizabeth M'Mullen 10s for supplying spirits in less quantity than that specified for off consumption. The evidence showed that a woman bought the liquor on the strength of a medical certificate granted in November last. The chairman said a doctor's certificate that spirit was required as medicine was only good for the day of issue.

Free Death Certificates.

THE Secretary of the War Office announces that certificates of death of soldiers killed in action or dying as a result of active service are issued to those concerned by the War Office upon application free of charge. In cases in which more than one certificate is required for insurance purposes, etc., duplicate copies are supplied.

Health Visitors.

Islington's Public Health Committee is recommending the Borough Council to appoint two health visitors to assist the Medical Officer of Health in carrying out the Public Health (Measles and German Measles) Regulations Act, 1916. The commencing salary of the proposed visitors is suggested at £100 per annum, rising by annual increments of £5 to a maximum of £125 per annum.

Medical Men in France and Italy.

It is stated that in France before the war there were about 20,000 medical men, of whom 3,000 resided in Paris. It is estimated that the income of the majority of the Parisian practitioners was less than £160 a year. There are eighty medical members of the Chamber of Deputies. In Italy there are 22,700 medical men, or about six to every 10,000 of population; in Naples, however, the proportion is twelve to each 10,000 inhabitants, and in Rome there is one doctor to each 10,000 of the population.

Presentation to Dr. J. Power.

A MEETING of medical practitioners was held at the Adelphi Hotel, Waterford, recently, for the purpose of inaugurating a testimonial to Dr. J. Power, Ardinnan, in recognition of the very valuable services rendered by him to the medical profession throughout Ireland in connection with the certification question under the National Health Insurance Act. As the settlement of this question has conferred considerable professional and financial advantages on the entire profession, the meeting was of opinion that the testimonial should command the spontaneous support of every one of its members. The following provisional committee was appointed:—Drs. M. E. Lynch, Mackesy, O'Brien, O'Sullivan, Quirke, C. Ryan, D. Walshe, P. Stephenson (Secretary), and J. H. M. Jellet (Treasurer).

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

57 CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s. post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

SMOKED HORSE.

At a general meeting of Harrison, Barber and Co., held yesterday, the Chairman said that they had lately embarked upon two new ventures—smoked horse and sausages—made, of course, from horses which were killed in perfect health. For both there was a growing demand.

LUBECK (Banbury).—According to the *Oxford Magazine*, the number of students in residence this term is 550 (including 34 B.A.s). This number compares with 1,087 in residence at this time last year, and with 3,097 in 1914.

RED CROSS STATIONERY.

RED Cross envelopes and stationery, with designs and sketches by noted artists, are to be sold in packets at from 1d. to 2s. 6d., and a limited collector's issue at prices up to 10s. The envelope bears a design by Mr. John S. Sargent, R.A.

A CLERGYMAN'S GRATITUDE.

THE REV. GEORGE COCKBURN DICKINSON, of Worcester Park, Surrey, a Governor of Christ's Hospital, bequeathed £200 to Dr. Irwin (Belfast) for "his attention when operating on my tongue many years ago, and I wish him to be told that I feel but for his skill I must have sunk under my agony."

MUNICIPAL DISPENSING.

OWING to the high price of drugs the Brighton Council has arranged to introduce a scheme of municipal dispensing at the local tuberculosis dispensary.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 23RD.

ROYAL SOCIETY OF ARTS (John Street, Adelphi, W.C.).—4.30 p.m.: Miss H. B. Hanson: Serbia as seen by a Red Cross Worker.

HUNTERIAN SOCIETY (1 Wimpole Street, W.).—9 p.m.: Demonstration:—Dr. R. D. Maxwell: Gynaecological Specimens. Discussion invited.

WEDNESDAY, FEBRUARY 23RD, AND FRIDAY, FEBRUARY 25TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—Course of Lectures on the Anatomy of the Human Body, for First-aid and Ambulance Students (open to all members of ambulance companies and first-aid classes): 5.30 p.m.: Professor A. Keith. 4 p.m. to 7 p.m.: Exhibition of Anatomical Preparations and Specimens in the Theatre on lecture days, and between 10 a.m. and 5 p.m. in the Hall of the Museum on the following day.

THURSDAY, FEBRUARY 24TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF NEUROLOGY) (1 Wimpole Street, W.).—8 p.m.: Clinical Meeting. Members who desire to show cases are requested to communicate with Dr. C. M. Hinds Howell, 145 Harley Street, W.

MONDAY, FEBRUARY 28TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF ODONTOLOGY) (1 Wimpole Street, W.).—5.30 p.m.: A Debate on "War Injuries of the Jaws and Face" will be opened by Mr. J. Levin Payne, and an Exhibition of Dental Splints, Models, Radiograms, Photographs, and other apparatus illustrating the same subject will be open from Tuesday, February 22nd, to Monday, February 28th. The Exhibition will be open from 11 a.m. to 6.30 p.m. each day.

ROYAL SOCIETY OF MEDICINE (SECTION OF SURGERY) (1 Wimpole Street, W.).—The President and Council of the Section of Odontology cordially invite the members of the Section of Surgery to the Debate on "War Injuries of the Jaws and Face," on Monday, February 28th, at 5.30 p.m.

Vacancies.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Barrow-in-Furness, Lancaster; Fintona, Tyrone; Staplehurst, Kent. Ingham Infirmary and South Shields and Westoe Dispensary.—House Surgeon. Salary £150 per annum, with residence, board, and washing.—Applications to John Potter, Secretary, Ingham Infirmary, South Shields.

Greenwich Union Infirmary.—Assistant Medical Officer. Salary £175 per annum, with furnished apartments, rations, and washing. Applications to the Medical Superintendent, at the Infirmary, Vanbrugh Hill, East Greenwich, S.E.

Salford Poor-law Union Infirmary.—Resident Assistant Medical Officer. Salary £300 per annum, with furnished apartments, attendance and rations in the infirmary. Applications to E. H. Inchley, Clerk to the Guardians, Poor-law Offices, Eccles New Road, Salford.

Coventry and Warwickshire Hospital, Coventry.—Third Resident. Salary £175 per annum, with rooms in the Hospital, board, laundry, and attendance. Gentlemen applying should be ineligible for military service. John A. Rudd, Secretary, Board Room, 8th February, 1916.

Hulme Dispensary, Dale Street, Stretford Road, Manchester.—House Surgeon. Salary £250 per annum, with apartments, attendance coal, and gas. Applications to Honorary Medical Secretary.

Cambridgeshire Asylum, Fulbourn, near Cambridge.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

Appointments.

ANWYL-DAVIES, T., M.R.C.S., L.R.C.P.Lond., Casualty Officer and Resident Anaesthetist at St. Thomas's Hospital.

BEATIA, S. L., M.R.C.S., L.R.C.P.Lond., Casualty Officer and Resident Anaesthetist at St. Thomas's Hospital.

BLUETT, D. C., Casualty Officer at St. Thomas's Hospital.

BEADLEY, F., M.B., Ch.B.N.U.I., Certifying Surgeon under the Factory and Workshop Acts for the Fintona District of the County of Tyrone.

CELESTIN, L. A., Casualty Officer at St. Thomas's Hospital.

DAVIES, L. M., M.R.C.S., L.R.C.P.Lond., Casualty Officer and Anaesthetist at St. Thomas's Hospital.

HARRIS, J. C. N., Resident House Surgeon at St. Thomas's Hospital.

HENSLEY, E. H. V., Resident House Surgeon at St. Thomas's Hospital.

HIGGINS, F. E., M.R.C.S., L.R.C.P.Lond., Senior House Physician at St. Thomas's Hospital.

HYMAN, O. H., Resident House Surgeon at St. Thomas's Hospital.

MARRIOTT, W., Resident House Physician at St. Thomas's Hospital.

NAIRNE, N. S., Ophthalmic House Surgeon at St. Thomas's Hospital.

ODDY, H. M., M.B., Ch.Ch.Oxon., M.R.C.S., L.R.C.P.Lond., Resident House Physician at St. Thomas's Hospital.

PHILLIPS, P. R. O'R., M.R.C.S., L.R.C.P.Lond., Casualty Officer and Resident Anaesthetist at St. Thomas's Hospital.

ROMANIS, W. H. C., M.B., B.C.Cantab., F.R.C.S.Eng., House Surgeon and Resident Anaesthetist at St. Thomas's Hospital.

SMITH, J. FOREST, Resident House Physician at St. Thomas's Hospital.

STORMER, H. G., Resident House Surgeon at St. Thomas's Hospital.

VEX, F. H., Resident House Physician at St. Thomas's Hospital.

Births.

ADAMS.—On February 13th, at Highlands, Leominster, the wife of Charles E. Adams, of a daughter.

BAKER.—On February 13th, at Torfield House, Hastings, Sussex, the wife of Dr. A. E. Baker, of a daughter.

BOWEN-JONES.—On February 15th, at 1, Walker Road, Cardiff, to the wife (*née* Nellie Parry) of Lieut. J. Bowen-Jones, R.A.M.C., a son.

DIXON.—On February 12th, at 51, Woodhurst Road, Acton, W., the wife of Dr. C. F. Lyne Dixon, of a son (prematurely).

GALE.—On February 14th, at Seoul, Korea, the wife of Dr. J. S. Gale—a son.

GILMOUR.—On February 15th, at West Meon, Hants, to the wife of R. Withers Gilmore, M.B., a daughter.

HAMILTON.—On February 14th, at Plas Mawr, Penmaenmawr, the wife of the late Dr. Graeme Hamilton, Ashton-under-Lyne, of a daughter.

LEDINGHAM.—On February 13th, at Yeoveney, Links Road, Epsom, the wife of Lieut.-Colonel J. C. G. Ledingham, R.A.M.C., of a son.

LUKYN-WILLIAMS.—On February 9th, at the Nursing Home, 13, Prince's Gate, London, the wife of H. T. Lukyn-Williams, M.B. (Temp. Lieut. R.A.M.C.), of a daughter.

WESTON.—On February 17th, at 2, East Ascent, St. Leonards-on-Sea, to Dr. and Mrs. H. J. Weston, a son.

Marriages.

GREIG-SCRIMGEOUR.—On February 16th, at Hemsby Parish Church, Staff-Surgeon Louis L. Greig, R.N., fifth son of the late Mr. and Mrs. David Greig, of Glasgow, to Phyllis, second daughter of Mr. and Mrs. Walter Scrimgeour, of Hemsby Hall, Hemsby, Norfolk.

DAWSON-BISSET.—On February 19th, at the West Parish Church, Aberdeen, George Forbes Dawson, Captain, R.A.M.C., younger son of William Dawson, 25 Westburn Drive, Aberdeen, to Catherine, second daughter of the late William Bisset, 38 Albany Place, Aberdeen.

MALLAM-SOMERVILLE.—On February 16th, at St. Benet's Church, Cambridge, Capt. Dalton Mallam, R.A.M.C. (T.), eldest son of the late Dr. G. B. Mallam, of Oxford, and Mrs. Mallam, of Sparsholt, Wantage, Berks, to Jessie Muirhead Somerville, niece of Mr. and Mrs. Robert Store, of Peldon Lodge, Colchester.

STEVENSON-OWENS.—On February 15th, at St. George's, Worthing, William Sinclair Stevenson, M.D., younger son of the late Rev. William Fleming Stevenson, D.D., to Mary Dorothea, widow of George Bolster Owens, R.N.

THOMAS-COULDRY.—On February 19th, Donald C. Thomas, Lieutenant, R.A.M.C., to Norah Alice, daughter of John Henry Couldrey, Esq., of Portsdown Road, Maida Vale.

TURNBULL-BAKER.—On February 12th, at St. Mary Abbot's, Kensington, Hubert Maitland Turnbull, D.M., Director of the Pathological Institute of the London Hospital, son of Mr. and Mrs. Andrew H. Turnbull, of The Elms, Edinburgh, to Catherine Nairne Arnold, younger daughter of Mr. and Mrs. Frederick Arnold Baker, of 20 Cottesmore Gardens, Kensington, and Flutters Hill, Longcross, Surrey.

Deaths.

ALEXANDER.—On February 14th, at Blackwall Lodge, Halifax, Reginald Gervase Alexander, M.D., J.P., co-heir to the Baronies of Burgh, Strabolgi, and Cobham of Kent, in his 69th year.

HEBERDEN.—On January 23rd, at a sanatorium, George Alfred Heberden, D.S.O., M.R.C.S., L.R.C.P., of Victoria West, South Africa, in his 56th year.

HUNT.—On February 15th, at Arosa, Switzerland, George Bertram Hunt, M.D., elder son of the late George Hunt, of Llovd's, aged 44.

MARCH.—On February 15th, at his residence, Nethergrove, Portesham, Dorset, Henry Colley March, M.D., J.P., F.S.A., formerly of Rochdale, aged 78.

PEMBERTON.—On February 15th, at Linden House, Banbury, Oxon, Clarence L. H. Pemberton, M.D., aged 80 years.

SPEIRS-ALEXANDER.—Died of wounds, on February 9th, in Mesopotamia, Alister Ralph Speirs-Alexander, M.B., B.S. Lond., Cant. Indian Medical Service, dearly loved son of Dr. and Mrs. Speirs-Alexander, Hampstead.

STOKES.—On February 10th, at Latchmere, Ham, suddenly, as the result of shell-shock in France, Lieut.-Col. John Wilfred Stokes, R.A.M.C. (T.F.), 3rd West Riding Field Ambulance, the dearly loved husband of Doris Stokes, and eldest son of Rev. A. and Mrs. Stokes, formerly of Mussoorie, U.P., India, aged 43.

TURNER.—On February 15th, 1916, at 6, Eton Terrace, Edinburgh, after a short illness, Sir William Turner, K.C.B., F.R.S., Principal and Vice-Chancellor of the University of Edinburgh, in his 85th year.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, MARCH 1, 1916.

No. 9.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravants les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

SINCE the outbreak of war there have been a good many cases reported in **Certificates.** the lay Press which turned on the question of medical certificates. Some of them have been provoked by mere irresponsible babble, such as that of the anonymous worthy who stated at Westminster that you could get a doctor to certify to anything (see "Periphery" of December 8th, 1915). Some of them have, however, been serious. There was, for instance, the case of the doctor who, to please a patient before the war, signed a recommendation for a passport in favour of a lady with whom he was not personally acquainted, an act of careless complaisance which got him into grave difficulties. Recently, the value of certificates for military unfitness has been much discussed; and more recently still a panel doctor has been charged with giving an insured patient a certificate of incapacity while, at the same time, advising the approved society that benefits should be withheld. This is, of course, to say the least of it, a very unmanly proceeding, and the doctor in question would surely have thought twice before adopting it had he been acquainted with the law on the subject.

Dangers. MEDICAL men are proverbially averse to giving certificates, but they would be even more chary of appending their signatures to these documents if they realised the risk they run by uttering a certificate which is not strictly in accordance with fact. The risk entailed is no less a one than that of being struck off the Medical Register. In spite of the training in accuracy which a scientific education is believed to cultivate, medical men are often very careless in their wording of a certificate. When, as in a lunacy certificate, they are asked very definitely to state facts, they ventilate opinions, and even when they mean to state a fact, the wording is so loose as to render the statement valueless. For some curious reason certifiers seem to have an objection to the present tense of the indicative mood; they prefer the present participle. I once saw a lunacy certificate in which the doctor wished to say, "The mother states that the patient went into the street in her nightgown." Instead of which he wrote, "going into the street in her nightgown."

The Law. BUT inaccuracy in wording may not only render a certificate valueless, it may, as I have already said, result in very awkward complications for the certifier. In a warning notice issued in November, 1911, the General Medical Council gave notice that "any registered medical practitioner who shall be shown to have given any untrue, misleading, or improper certificate, whether relating to several matters specified below or otherwise, is liable to be adjudged by them to be guilty of 'Infamous conduct in a professional respect.'

CERTIFICATES.

- (a) Under any statute relating to births, deaths or disposal of the dead.
- (b) Under the Lunacy Acts.
- (c) Under the Vaccination Acts.
- (d) Under the Factory Acts.
- (e) In relation to children or to excusing school attendance.
- (f) In connection with sick benefit, insurance and friendly societies.
- (g) In connection with workman's compensation.
- (h) In connection with Naval or merchant shipping.
- (i) For procuring the issue of Foreign Office passports.
- (j) For excusing attendance in courts of justice, in the public services, in public offices, or at ordinary employments."

Latin. THE powers of the General Medical Council are thus very considerable, and medical men would do well to lay this warning notice to heart when, pen in hand, they sit down to sign a certificate. There is one matter, however, in which the powers of the Council are not as extensive as they were thought to be. Young men who study medicine in universities with a view to qualifying are required by the General Medical Council to pass a preliminary examination in subjects of general education before entering on their medical studies. The regulations of the Council have always required that Latin shall be one of the subjects of the preliminary examination. Some years ago, however, notwithstanding the regulations of the General Medical Council, the University of London

decided to admit medical students to its examinations and degrees without demanding Latin as one of the subjects of the matriculation examination. Such medical students were consequently never recognised on the register of medical students published by the Council. Nevertheless, after the necessary period of study and passing of the necessary examinations, the names of the new medical graduates were sent up to the Registrar of the General Medical Council for insertion on the Register of Qualified Practitioners. It now appears that according to the Medical Acts, although it had never recognised them as medical students, the General Medical Council cannot refuse to accept the Latinless graduates as qualified medical men.

Live Languages. WHATEVER there is to be said in favour of a classical education—and there is a great deal to be said—it is obvious that the amount of Latin which suffices to satisfy the examiners in a “prelim” is no guarantee of classical scholarship. The “little Latin and less Greek” which it used to be necessary for students to produce represented nothing of any value, whereas the same amount of French, German or Spanish would serve as a very fair foundation on which to erect a superstructure of real familiarity later on. Complete ignorance of Latin must be a very serious drawback to anyone studying medicine, but as soon as he is qualified the need for Latin disappears. In the case of a foreign language the position is reversed. Familiarity with French, for example, is of little or no use to the student, but to the qualified man it is an inestimable boon both professionally and socially, a fact of which its possessor becomes increasingly conscious as time goes on.

The German Language. I SEE that there is a movement on foot to discourage the teaching and learning of the German language. Medical students and young doctors will do well to take no part in this movement. I think the movement is stupid and petulant from every point of view, but from that of the scientist in any branch it is suicidal. The Germans themselves afford the most convincing proof of this. By no means their least powerful instrument of insinuation into the vitals of the political and commercial life in France and Britain has been their extraordinary familiarity with the languages of the two countries. If the Hun had not been polyglot he could never have succeeded in this colossal rattle into barbarism. As an additional precaution against the success of any future attempt of the same kind, we should encourage our young men to imitate his educational methods by familiarising themselves with his language. And more especially scientific young men, for when even the Devil's Advocate has said his worst against the Hun, there will always remain to his credit careful scientific work which is best studied in the original.

Mortality of Male Babies. WHEN venturing my explanation of the greater mortality of infant boys over infant girls, I fully expected to “draw” somebody, but I hardly hoped to land so substantial

a fish as Dr. W. E. Fothergill, whose letter, which appeared last week, p. 171, arrived too late for me to comment on. Than Dr. Fothergill no one is more competent to make a contribution to this subject, and I hope his humorous and learned letter gave much pleasure to the readers of the MEDICAL PRESS AND CIRCULAR as it did to me. Of course he is right in his contention that males are katabolic and females anabolic; and that the female baby's anabolism confers upon her a very much greater resistance to uncongenial environment than is present in the katabolic male baby. This affords a good, sufficient and an interesting reason for the difference in the respective death-rates. But I do not think it affords any argument against my view that a male is a higher evolutionary product than a female. The dormouse is surely an organisation of a lower type than the mouse who is not dormy.

Ignorance and the War. ON the subject of child mortality in general it has often been said that ignorance is more deadly than war. The degree of truth in this trite saying has been brought out by a comparison made by Mr. Robert Parr, of the Society for the Prevention of Cruelty to Children: “In the first fifteen months of the war 109,725 soldiers and sailors were killed or died; whereas during 1913 the number of children who died under five years of age was 140,957, and of these 95,608 were infants under a year.” Even if it be supposed that a certain proportion of these young deaths were quite unavoidable, the fact remains that one year's infantile mortality is greater than the havoc caused by fifteen months of the most appalling military slaughter in history. Suffragettes are fond of saying that women should be given the vote because they know more about children than men do. They do not seem to be able to apply this exclusive knowledge to any very practical purpose.

Slates and Roller Towels. MR. L. R. TIPPINS, of Mistley, Essex, writes to *The Times* as follows:—“About thirty years ago you printed a letter from me pointing out the dangers of using slates in schools. Being before its time it was much ridiculed by some who called themselves educationists. I now write to protest against the reintroduction of the filthy practice of using slates. It would be no economy, and would not even save money. It would cost a good deal of coin and very many lives. In the light of our present knowledge no man of common sense can advocate a practice that is little short of murder.” Mr. Tippins is, of course, perfectly right, and I wish him every success in his campaign. Some Medical Officers of Health pay great attention to these matters, but there are many who do not. Slates are undoubtedly very insanitary, and should be prohibited under severe penalties in every and any school. Worse even than slates, however, are those filthy and dangerous abominations known as roller towels which abound not only in schools but in hotels and even in first-class restaurants. The amount

of ringworm, ophthalmia and other filth diseases for which these relics of barbarism must be responsible it would be impossible to gauge. Sanitary authorities should suppress them with a firm and untiring hand.

Frae the North. A FRIEND from the North writes as follows:—"A healthy medical septuagenarian from Dennistoun, Glasgow, voices a grievance that many have felt but sat still under.

There are many elderly medical men, some retired and some still going strong, who have expressed their eagerness to fall into line with the manhood of the nation and do what they can in our present neck-or-nothing national struggle. Those to whom I have spoken have had their letters recognised most politely—but that is all. Then appears a letter from Professor Ogsten setting forth the great need of medical men and women. Small wonder that the 'old boys' feel sore after having offered their services and having so far only been ignored. When one notes the number of medical men who have already donned khaki and left their work behind for others to do, one can hardly believe that there is such a dearth of men as the outcry would indicate. At present there is no scarcity of surgeons or physicians in our military hospitals about here. One-quarter of the men could easily do all the work that is to be done. Our military medicals might take a lesson from the tramway department of any big town, which always has a 'break-down gang' ready to be sent to where the work is. The bulk of the work in our military hospitals at home could be done by good house-surgeons—though there now and then crops up a case where large experience is a necessity; but it does seem somewhat wasteful for surgeons of thirty years' experience, men at the head of their profession, to be doing circumcisions, operating on varicoceles (some of which could only be seen in the relaxed summer scrotum) straightening hammer-toes, etc., etc. But it fits in with the idea of that charming phrase-maker Lord Rosebery, describing our past methods as 'muddling thro'."

From the Front. ANOTHER friend, in the South, sends me the following extract from a letter recently received from his son, an R.A.M.C. officer at the front:—"It is not altogether fair to criticise the existing administration. For things as they are, there is an undoubted plethora of medical and surgical personnel, but in the event of serious fighting and anything like a far-flung battle, we should all be working up to our eyes. I don't quite follow the charge of waste of energy. At the times when there has been a 'push' the demand for medical officers has always exceeded the supply, but when there is fighting you cannot run doctors up and down the country without hopelessly upsetting all organisation. As long as there is a man who is likely to be sick, be it only with a headache, there must, according to the army régime, always be a doctor within reach. . . . One friend of mine said he managed to keep dry in the awful rains by wearing a thin transparent

oilskin under his ordinary waterproof. I have seen ladies wearing these things at home."

Organise. THE criticism which has been directed against the authorities for the want of organisation and consequent wastefulness in medical men refers not to the state of matters at

the front, but to what is going on at home. The best way of utilising medical material in the fighting area is one upon which military men, and military men alone, are competent to give an opinion. The rule which provides that a doctor shall be available for anyone who is in any way sick is both humane and expedient. In its application it may seem to entail a certain wastefulness, but that is clearly unavoidable. On the question of the judicious and economical utilisation of medical officers at home, any thinking man who is in touch with such officers is capable of forming an opinion. So far, from such people I have heard but one opinion, and it is to the effect that the organisation is bad; a plethora of officers in some places and a dearth in others; surgeons put to do the work of physicians and *vice versa*; well-known operators obliged to ask permission to operate from men who, the day before yesterday, were sitting at their feet in the class-room, and so on. What is wanted is a business man accustomed to large scale organising to act as assessor to the present military authorities.

Emetine in Psoriasis. AN accidental experience with emetine hydrochloride leads a writer in *Therapeutic Notes* (November, 1915, p. 131) to believe that this remarkable remedy exerts

a favourable influence upon psoriasis. The first case received a half-grain of emetine hydrochloride by hypodermic injection for a severe alveolitis. Soon after the injection the skin manifestations, which were, of course, of longer duration, began to disappear. Three cases of psoriasis have been treated with emetine with highly satisfactory results. Even the most experienced dermatologist has often had to confess himself defeated by psoriasis. Here is a new idea which is worth putting to practical tests.

Dr. Percy Lewis. DR. PERCY LEWIS, of Folkestone, who writes this week on the "Treatment of Nervous Disorders," is the son of the late Dr. Henry Lewis, also of Folkestone, who was the first President of the Balneological Society, which was founded just upon twenty years ago. Dr. Percy Lewis, who has himself been a President of the Society, is a "King's" man, and has been one of the leading practitioners in Folkestone for several years. He has himself been President, and is one of the most loyal supporters of the Society (now a Section of the Royal Society of Medicine) which his father did so much to establish. Since the outbreak of war, Dr. Lewis has given a great deal of time to the care of the wounded. In conjunction with Dr. Wainwright he inaugurated and equipped a new

hospital at Folkestone, which is entirely given over to the military.

DR. WITHERS GREEN, the author of the article on "Talking," is an old Withers Green. "Guy's" man, whose time is largely given over to assurance work.

He lives in Wardrobe Court, one of the quaint and picturesque backwaters close to St. Paul's Churchyard. It is said of the late Sir Lawrence Gomme that he knew more about old London than anyone had ever known. If he knew more about certain parts of it than Dr. Withers Green he must have known a great deal. The latter can sometimes be persuaded to take his friends round his favourite haunts. On those occasions, with the aid of a megaphone, he lovingly dilates upon the points of historical interest which abound in the neighbourhood of the Temple and the Inns of Court, every corner of which he knows, as the French say, like his pocket.

SINAPIS.

CURRENT TOPICS.

Anti-Germanism and the Medical Profession.

As a medical journal we have, of course, no concern with political questions, whether domestic or foreign, and we have no wish to criticise the so-called anti-German movement as regards its political or economic issues. It has, however, certain relations to scientific progress which touch us closely, and which make it necessary for us to make a few comments. As we understand it, the essence of the anti-German movement, as it is organised in the Anti-German League is to perpetuate for times of peace the national hatred which is natural and perhaps useful in time of war. When the war of Dreadnoughts and machine guns is over, we are, say these propagandists, to maintain an economic and social state of war against our present foes. Not only is Germany always to be the foe, but individual Germans are always to be our personal foes. We do not know whether this would be good economics or not, but we are in no manner of doubt that such a mental attitude would be highly detrimental to the development of science. Science knows no international limits. We cannot shut out from thought and consideration the work of a thoroughly scientific and efficient people, whatever reason we may have to disapprove of many of their activities. It is petty to make use of present emotions to belittle the contribution of Germany to scientific progress in the past, and it would be very short-sighted to attempt to prevent such contribution in the future. Let us by all means see that the danger of Germany politically should cease to exist, but let us also, if we can, make sure that the useful activities may be as far as possible unhampered. Medical men are well aware of the services to humanity rendered by German men of science in the past. They are also aware of the high place in the chemical industries and in the manufacture of scientific apparatus which German energy has won, and more than most other classes they feel the deprivations

which necessarily are brought about in war-time. They do not wish such deprivations to be permanent. In view of these considerations we do not wonder that some surprise should have been caused by the fact that the hospitality of the Royal College of Surgeons in Ireland should have been given for the purpose of inaugurating a branch of the Anti-German League in Ireland. The Medical profession, as such, should not be identified with the movement, though, of course, we have no desire to limit the political activities of individual medical men.

National Nerves.

WE have, on one or two occasions, since the outbreak of the war, commented on signs of "nerves" which threatened to interfere with the cool judgment so necessary in a time of national danger. These signs have been more or less intermittent, and have not, we think, been evidence of any deep-seated disease. The recent Zeppelin raid on the Midlands has, however, caused some recrudescence of symptoms of nervousness which should not be fostered. It is with some interest we note that the *Spectator*, in its last issue, deals with the matter from much the same standpoint as ourselves. In an article entitled "The Neurasthenic Press," it shows the inherent morbidity of the conduct of certain newspapers. Quoting from some medical work in its description of neurasthenia, the *Spectator* finds the description "positively uncanny in its application." We cannot do better than quote the paragraph:—"In the first place, we are told that the symptoms of neurasthenia are as follows: (1) A general feeling of malaise 'combined with a mixed state of excitement and depression'; (2) Vertigo and 'a transitory clouding of consciousness'; (3) 'Weakness of memory, especially for recent events'; (4) 'Morbid heatings, flushings and sweats.' Next, we are told that neurasthenia shows many strange and peculiar symptoms, such, for example, as *Batophobia*—fright of things falling.' Further, there are to be observed 'mental ruminations,' in which there is a continuous flow of connected ideas from which there is no breaking away. Sometimes, too, there is '*Arithmomania*'—an imperative impulse to count (*cf.* the persistent effort of the group of newspapers in question to add up the German losses). Again, neurasthenic cases 'often exhibit a marked emotionalism and readily manifest joy or sorrow; they may be cynical, pessimistic, introspective, and self-centred, only able to talk about themselves or matters of personal interest, yet they frequently possess great intellectual ability.'" We entirely agree with our contemporary.

War and Eugenics.

At a meeting of the Royal Statistical Society held on Tuesday, February 15th, Major Leonard Darwin read a Paper—"On the Statistical Enquiries needed after the War in connection with Eugenics." Major Darwin began by pointing out that, though it was difficult to estimate the casualties in this war, ours might now be in number as high as 6½ per cent., and the German's possibly

between 20 and 30 per cent., of the number of the fighting men available. Though all must devote all their main energies to winning the war, yet some thought might even now be given to the enquiries which might profitably be instituted, when peace gave more leisure, concerning this racial damage. Though the best estimate should then be made of the total loss of progeny because of the war, this would tell nothing as to racial effects, which would depend on whether those killed were above or below the average inborn qualities. The Napoleonic wars were said to have diminished the stature of the French nation; but whether this would be the case with us would not be ascertainable for many years. Even if it would be impossible actually to measure the racial damage done by the war, enquiry as to its probable effects should be made. The classes sifted out before the fighting force entered the fighting line consisted of the shirkers, the rejected on enlistment, the men turned out of the service or kept at home because of incapacity, and those invalided from abroad. True, many were kept at home because of good qualities. Again, courage exposed men to great danger in war, whilst disease tended to pick out the weakest. Balancing these conflicting considerations, the conclusion arrived at was that war unquestionably killed off the better types and was therefore highly dysgenic. The anticipation of racial damage was strengthened by considering the death-rate amongst officers, who formed a still more highly selected class of the community. Much was already known as to the laws of heredity, and on these laws investigations as to the probable future racial damage to the nation could be based. The active causes of the damage would not however, cease with the war; because the birth-rate of the higher types would continue to be adversely affected. As to mitigating these racial evils, those born in the last eighteen years would form an entirely undamaged section of the community, and it would be increasingly necessary for the next twenty years to inculcate a belief that where both parents are fairly healthy it was immoral and unpatriotic to limit the size of the family, except in view of bringing up the children in comfort, though not necessarily in luxury, and of there being fairly wide intervals between births. It followed also that the racial damage would be at its worst when peace was declared, and the checking of the multiplication of the unfit would never be more needed than then. He looked at all these matters, however, as part of the whole great question of racial advance or decline on which the fate of nations so largely depended: and he was actuated by the fear that in the excitement of party strife, all eugenic reform would be pushed on one side to make room for topics of more immediate interest, in which case there would be grave danger of our country slowly drifting down the hill of racial degradation and of never again occupying its past high position in the councils of the world.

Examinations.

CONCLUSIONS from insufficient premises are to be deplored in all mental processes, but above all in the case of examination candidates. The proposition is very generally allowed, we are aware,

yet even to-day there exist medical examiners who wax impatient if a conclusion be not speedily arrived at; and evidence of such impatience reacts most unfavourably upon the candidate, causing his answers to become indefinite and hesitating. An examiner in morbid histology, for example, who strictly adheres to a three minutes' time limit for each microscopical preparation, and who presses early for a positive statement as regards the nature of the lesion in question, does the undergraduate scant justice, and returns a result list which is no index to the individual merits concerned. If he but take the time to allow the candidate to isolate and identify the elements of the section, aiding him by a few judicious questions, and stimulating the synthetic powers, he may come to be surprised at the result. Persistence in the opposite methods aggravates the disastrous practice of *spotting*, which cannot be too strongly condemned. Moreover, in the case of final qualifying examinations in clinics, credit should be given rather to extent and accuracy of observation, than to rapidity of deduction. It remains a matter of surprise to many of us that in the space, say, of one hour, as much is expected of an unqualified student as it is allowed to a man of many years' practice to postpone for days, and perhaps indefinitely. The abuse described is not universal, but is present, and fails in discrimination and intelligence.

Tales of a Scotch Professor.

A WELL-KNOWN Scotch professor, vigorous in body and mind, with a syncopated style of speech, tells the tale:—"We were—travelling—to—London. At the Central—Station—an intoxicated person—had got in—and his—language was painful—and frequent and free. There were—ladies—present. He—was—profane—and—worse. We—thought—how—to—keep—him—quiet. So—we—dislocated—his—lower jaw—at—Beattock. Ah—but—we reduced it—before we reached—Euston."

The same professor was consulted by an elderly man who had a tuberculous testicle; he advised the patient to have it removed. "Removed? Cut off? No, no," said the patient, "I'll get more skill before that." "Ah—but—where will—you get it?" asked the professor. "In London, of course." They parted.

Some weeks after the patient returned to him for another consultation. "Ah—and so you—left here—for more—skill? How—did—you—get on?" "Oh, I went to Sir X—Y—, in London." "And what—did—he—say?" "Oh! he told me to paint the part with iodine!" "Ah! I quite—agree—with—him—but—have it removed—first!"

Please visualise the old gentleman doing sepiawork on the detached organ!!!

Do you remember the old Professor in whose class were more than the usual number of MacDonalds? One of them was, at the end of the lecture hour, protesting that his name had not been called. "What is your name?" "MacDonald." "Oh! of course it's MacDonald, but which one are you?" "E. F. MacDonald." The old man looked up the roll-book, and after examining it said: "It's all right, sir, it's all right; you are marked 'present.'" And then in a dreamy, introspective way, "There's so many of you dashed Macdonalds about, I don't believe there ever was any Massacre of Glencoe."

Carbolic Acid in Tetanus.

At the meeting of the Medical Society, Dr. Lesage, of the 6th Army, described a method of treatment used by Dr. De Montille in tetanus, giving

good results, even in very acute cases. His method is Bacelli's, modified as follows:—

Carbolic acid, 1 gramme.

Ether, Q.S. to dissolve.

Sterilised olive oil, 10 grammes.

In this formula the carbolic acid is less irritant and less toxic, a smaller dose being efficacious and a smaller number of injections (intramuscular) being required; not more than one or two per day were used by the author. 1.50 gramme of carbolic acid may be injected each day without inconvenience, although one-sixth of that quantity has been found sufficient to give the desired effects. The following points are to be noted in connection with this method:

1. The patient is *very rapidly* calmed; he is, so to speak, de-tetanised.
2. The great simplicity of the method; one or two intramuscular injections per day being sufficient.
3. The very manifest effect of even quite a small dose, the author using 20 centigrammes of carbolic acid per 24 hours—*i.e.*, 2 c.c. of the mixture (maximum dose "pro die"), and reducing the daily dose to $1\frac{1}{2}$ or $1\frac{1}{3}$ c.c. in a few days' time.
4. Real and *durable* recovery being obtained in 10 or 12 days after beginning the treatment in serious cases.

Bradycardia in Soldiers.

Dr. Gouget has noted the frequency of bradycardia in soldiers, wounded or sick, coming directly from the front. Out of the 133 of these men, without any fever, one third presented a pulse rate of between 58 and 38. Other men had relative bradycardia in the course of febrile affections, usually accompanied with a rapid pulse. There was generally at the same time slight irregularity of the pulse and lowered blood tension. In the majority of cases these phenomena disappeared in a few days or two or three weeks. Occurring in the course of various affections, they seem to be quite independent of the nature of the latter, and are due to over-fatigue.

Army Malingering.

In France, where conscription obtains, many and various are the ways employed by a certain category of men to get out of military service, or if incorporated, to obtain their discharge or "réforme" as it is called here. The men of the Army Medical Service, however, are very wide awake, and sooner or later all the "little dodges" are discovered. Dr. Lombard has described a method by which shamming unilateral deafness may be exposed. In a bona-fide case of unilateral deafness, if the patient be made to read out loud, and one suppresses the hearing alternately on each side, when the sound side is suppressed the patient immediately raises his voice very markedly because he cannot any longer hear himself speak, the voice falling to its former intensity as soon as the hearing is restored.

Obviously when a man has natural hearing on both sides he does not raise his voice when one side is suppressed, for he continues to hear with the other. Dr. Poyet has used this method with success, and the means he employed to suppress hearing consisted in a jet of tepid water directed into the external auditory meatus; the gurgling thus produced gives the desired effect.

One of the latest tricks has been described at the "Société de Chirurgie" by Dr. Laval. It consists in the production of gangrenous abscesses by means of subcutaneous injections of petroleum. This method has been extensively used of late,

and Dr. Laval has studied the whole procedure. An ordinary hypodermic syringe is used, and the injections are usually made in the lower limb on the inside of the knee; also in the upper limb, arm, forearm or hand.

Cellulitis is produced and the skin presents blisters with pus. Fluctuation appears towards the fourth day, and when the collection is increased a certain amount of pus issues, and one usually finds that trabeculae divide the cavity into compartments. The characteristic point, however, is that as soon as the cavity is opened a smell of petroleum is noticed. In some cases the odour was absent, but by rubbing a compress in the cavity the odour was at once detected. Suppuration continues for a long time, and sometimes there is necrosis of muscles and tendons: in one case Dr. Laval had to amputate. Secondary infection may take place with septicaemia.

Traumatic Deafness.

DEAFNESS, unilateral or bilateral, partial or complete, has been rather frequent during the course of the war amongst soldiers, the causes being either some cranial traumatism or indirect concussion due to explosions of shells. At a recent meeting of the Academy of Medicine, Drs. Lannois and Chavaune gave their conclusions from the prognosis point of view on the subject, based upon the study of over 1,000 cases. The prognosis depends on the following points:—

1. The previous condition of the auditory apparatus. Individuals who had been suffering from chronic middle-ear trouble, suppuration or sclerosis, furnished, after labyrinthine concussion due to the explosion of shells, a much larger proportion of cases of deafness or diminished hearing than normal individuals.
2. The existence or not of direct cranial traumatism. Deafness was habitual in traumatic mastoiditis; frequent in traumatism in the neighbourhood of the ear; rare in fractures of the vault. In these latter cases deafness was usually unilateral. In the absence of direct traumatism, labyrinthine concussion rarely gave rise to deafness; in 615 cases of labyrinthine concussion with or without rupture of the tympanum, there were only 2 per cent. cases of definite bilateral deafness.

PERSONAL.

PRINCE ALEXANDER OF TECK has become chairman of a committee formed to promote the election of Professor William R. Smith, M.D., as one of the Sheriffs of the city at the next election.

DR. J. S. CRONE, J.P., of Kensal Lodge, Willesden, has been appointed deputy coroner for West Middlesex, in succession to Mr. R. Kemp, who was recently appointed coroner.

MAJOR H. E. STANGER-LEATHES, I.M.S., has been appointed to act as Personal Assistant to the Surgeon-General with the Government of Bombay, in addition to his military duties.

SIR JOHN ROSE BRADFORD, K.C.M.G., C.B., M.D., F.R.C.P., Colonel, A.M.S., has been elected President of the London and Counties Medical Protection Society, Limited, in place of the late Dr. George Allan Heron.

MAJOR PRIESTLEY and CAPTAIN VIDAL, of the R.A.M.C., have returned to England from Germany. These are the two officers mentioned by Lord Robert Cecil in the House of Commons as having been detained by the Germans for more than half a year in violation of the Geneva Convention.

~~ORIGINAL PAPERS.~~

TREATMENT OF NERVOUS DISORDERS.

By PERCY LEWIS, M.D.

Honorary Physician to the "Nursing Homes" Military Hospitals, Folkestone.

REGULAR attendance for some months at one of the large hospitals for nervous diseases has induced in the writer certain reflections which it is here endeavoured to put forth.

Treatment in such institutions seems to be devoted far more to diagnosis than to cure. What is meant is that the painstaking attention to the minutest detail, and the accuracy of inductive reasoning which is exhibited in the making of a diagnosis, is by no means so much in evidence when the question of treatment is under consideration. A house physician at one of these hospitals, when asked what he thought of the treatment, summed his opinion up thus: "Everything is syphilitic; and, if it is not, you cannot do anything." This was, of course, an overstatement of what obtains, but there is a modicum of truth in his dictum.

For purposes of discussion, nervous diseases may be divided into three classes—viz., those in which there is a structural change, functional cases where there is no obvious structural change, and mixed cases.

In the first class, the most interesting are those which are characterised by sclerosis. The routine treatment consists of rest in bed, massage, electricity, salvarsan and mercury, often even if the Wassermann reaction be negative, and so on.

In considering whether these usual methods, whose success is mostly temporary, constitute all that can be done, it behoves us to review similar morbid processes in other organs with the treatment in those cases adopted. Further, we have to note the results of those treatments, and to see whether, having regard to the greater vulnerability of the nervous system, the application of similar methods to it would be likely to be followed by better results than are at present obtainable.

Analogy from the causes of sclerotic changes in other organs would point to similar changes in the nervous system having also a toxæmic or micro-organismal origin. A large number of nervous disorders are already acknowledged to have such a source. To mention some—neuritis, anterior poliomyelitis, myelitis, cerebro-spinal meningitis, chorea, Landry's paralysis, subacute combined degeneration of the cord, cerebral and spinal syphilis, general paralysis, and locomotor ataxy. For convincing proof of the bacterial genesis of brain and cord affections, reference should be made to the work of Drs. Orr and Rows, published in 1914 in the "Proceedings of the Royal Society of Medicine," and also in *Brain*. In these papers the investigators not only proved the fact, but they also showed the paths of infection of the nervous system from such diverse septic foci as carcinoma of the tongue, erysipelas of the face, bed sores, psoas abscess, and cystitis. They further formulated the laws which govern such infections—as, for instance, that "the locality of the lesion in the spinal cord always corresponds with the nerve supply of the infected focus."

That very great improvement can be obtained when the cause is syphilitic by rigorous anti-syphilitic remedies suggests that anti-toxic prin-

ciples applied in cases due to other causative organisms would be likely to be followed by similar good results.

We know that from the earliest moments of our existence to its termination we are continually subjected to the attacks of micro-organisms, and that our health and life depend on a successful defence. As long as our defensive arrangements are effective we are free from the assaults of the enemy. But at various times, and for various reasons, our defence breaks down, and one or more of the allied forces obtain a local foothold, or a general occupation. Those who study the diseases treated at baths and spas know how common it is to find there local footholds, or septic foci, existing all unsuspected by their hosts, who go for treatment for quite different reasons. One need only instance arthritis. In this disease it is a very common experience to cure the complaint solely by treatment directed to the local septic focus. Such foci may be found in the mouth, in the posterior nasal space, in the maxillary sinuses, in a bronchial catarrh, in the ear, in the big bowel, in the gall ducts, in the kidneys—and, in fact, almost everywhere.

Now if such comparatively coarse structures as joints should thus be affected and destroyed by low-grade septic organisms, it is obvious that it is more than likely that the more delicate nervous centres would also be liable to be a prey to similar attacks. With the evidence which we have of the effects produced by the spirochæte, the proposition has surely only to be suggested to be at once accepted. Therefore it is contended that in all cases of nervous disease, the preliminary to all treatments should be a thorough search for, and cure of, all septic foci.

This search is not at all unnecessary even if the syphilitic origin of the complaint be admitted. It is gradually coming to be recognised that the symptoms known as syphilitic may now be divided into two classes, viz., syphilis, *pur et simple*, and syphilis plus sepsis. It is, therefore, just as important to detect the septic foci in this disease as in any other. Consider how much improvement is effected in many syphilitic conditions of the nervous system, and consider also how much more might possibly be accomplished if the other causes of infection were at the same time removed. Syphilis, in fact, predisposes to other septic infections, just as any other invading organism does. It follows, then, that chronic sepsis of any kind is apt to be a mixed one, and the failure of treatment directed against any one, may be due to others being undetected and unattacked. So that the perfect cure of oral sepsis, discovered in a sufferer from disseminated sclerosis, if it be not followed by amelioration of the symptoms, does not necessarily prove that the principle of that treatment was wrong, but only that it was not the source or not the whole source of the disease in question.

In books on nervous diseases, the cause of sclerotic conditions is given in a very indefinite

manner as due to possible congenital conditions, or as following fevers, injury, etc. They mention in the same indefinite manner the possibility of a toxin, but when they come to treatment the same round of rest, massage, electricity, etc., is given. This is just the same course which used to be prescribed for arthritis at the Spas, before the Spa physician recognised the rôle of sepsis in its causation. It was long before this view gained general acceptance, and no doubt it will be long before similar acceptance is granted to the idea of the septic cause of sclerotic nervous conditions. But as President Wilson has said, "principles are eternal," and that which causes sclerotic changes in kidneys, liver and lungs, must also be the cause of sclerotic conditions in the nervous system.

It should be mentioned that just as the use of rest, massage and electricity in nerve complaints is followed by temporary improvement, the same temporary result is obtained in arthritis. Since the use in addition of treatment, directed against the toxic elements of the disease, has become more common, far better results and many more cures are obtained. These cases are constantly being reported in current medical literature.

In fact the more one considers the matter the more one discovers how the condition of sepsis pervades the whole field of medicine. The late Mr. Labouchere was fond of saying that "medicine was mostly a matter of aperients." In so far as that the intestinal tract is a large source of sepsis, this opinion is correct. Examples crowd into one's mind of common experience corroborating this view. The well-being experienced after a suitable aperient is simply a case of increased efficiency from the removal of toxins. A doctor who suffered from attacks of cardiac irregularity, often lasting for months, consulted various specialists without experiencing relief. On one occasion when the condition had existed for four months, a general practitioner told him that he only required an intestinal disinfectant in the shape of a dose or two of calomel. This cured him at once, and he now informs me that a grain of calomel will always remove the symptoms in a few hours. He can obtain similar results, though not so quickly, by abstaining from food, drinking large quantities of water, and taking walking exercise. In either case his cure is conducted on sound bacteriological principles.

In cases of epilepsy, the routine continuous administrations of bromides to control the attacks is merely an instance of treating a symptom without attacking the cause. The writer is entirely convinced that far better results free from injurious effects are to be obtained by other means. Just as the doctor's heart above-mentioned is peculiarly susceptible to toxins manufactured in his alimentary canal, so are the nerve centres in epileptics peculiarly susceptible to similar intestinal bacterial results. The treatment then consists not so much in controlling the symptoms as in attacking the source. Strict intestinal antiseptics by diet and drugs, and regulation of the general health by fresh air, exercise and suitable diet so as to conduce to the normal and efficient action of the whole body, is not only theoretically right, but practically is now in many quarters admitted to give the best results. It may be objected that if the attacks of epilepsy are due to intestinal toxins, how is it that a regularly acting cause produces an intermittent result? Why, for instance, does an epileptic seizure end, and how do you explain that theory explain *petit mal*? The answer would be, that just as the doctor in the heart case can cure the uncomfortable action of his cardiac irregularity by exercise, so does nature in a fit work off

the excess of toxins by the violent muscular work performed in an epileptic seizure. The recovery from *petit mal* represents nothing more than the ebb and flow of the battle between the opposing forces of the bacterial toxin on the one hand, and the defensive forces of the body on the other. If one watches the procession of epileptic patients at an out-patient department for these cases, one is struck with the aspect of chronic toxæmia which characterises them all from the youngest upwards. The conditions of epilepsy and convulsions in children have much in common. In the latter the toxic conditions have long been admitted. Whoever thinks of treating them by bromide alone if at all? Calomel or other antiseptic aperient is always the sheet anchor of treatment, followed by strict diétetic instructions. How seldom are such methods adopted in at any rate the out-patient department treatment of epilepsy? To what is the success of epileptic colonies due, if not to the effect which a life directed to general conditions of health has on the intestinal functions? It is unfortunate that the colonies are only used for those advanced cases where the "habit of epilepsy" has become confirmed, a point to which we will return later on.

In most nervous diseases a septic element can be found, and indeed the number of such conditions being admitted to the category is constantly being increased. Neurasthenia has at last been admitted, grudgingly by some, in a whole-hearted manner by others. The result of partial or complete admission by the physician in charge is represented by the treatment which he adopts. Who believing entirely in the toxic cause treats the condition by electricity as their main weapon of attack? If one were formulating principles for treatment of nerve diseases, the first would be "Search for a septic element," and it would be to this element that treatment would be primarily directed. Not of course solely, for few cases are as simple as that. Most cases are instances of vicious circles, and other points in the circumference demand attention if the war is not to be too prolonged.

The symptom of *petit mal* and the ebb and flow of the battle, has its counterpart in many other nervous conditions. Many such notoriously exhibit stages of progression and periods of comparative calm. This again is only to be expected, and is to be explained by an increase or diminution in, or absorption of, toxic material. Especially would one expect this in the case of intestinal sources, where the conditions fluctuate more than in most other foci. In disseminated sclerosis, such periods of increase with remissions and improvement are quite the rule, and there is accumulating evidence of the septic origin of this complaint. The writer has under his care a case which commenced after an attack of colitis contracted in Egypt. Even after two years, a vaccine made from the fæces brought about such an improvement that the patient, who previously was quite unable to move a step, could in a few weeks with one hand on a bath chair manage to walk a mile. Other cases may be found in the medical journals of recent years. For instance, Dr. Bolton, of Nottingham, records a case of disseminated sclerosis where the well-established symptoms, which had existed for six years, were almost entirely removed by antiseptic measures applied to the septic focus, in this case a chronic atrophic rhinitis. He says that "under the antiseptic nasal treatment her walking powers improved, and she gained control over the sphincters. Three years later the nose still receives attention, but nothing is done for the spine. The sphincters give no trouble, walking is still improving, and she is able to perform all her

ordinary duties without difficulty. Apparently the cause has been found and kept under control and the disease checked." In another case of disseminated sclerosis recorded by Dr. Lyon Smith, treated by a vaccine made from the cerebrospinal fluid, the improvement is mentioned as most striking. In the *Lancet* of September 5th, 1914, Mr. White Robertson in discussing the paths of infection in streptococcal fibrositis from oral sepsis, says that Morse-key paralysis, telegraphist's, writer's and typewriter's cramps, are all instances of streptococcal fibrositis. He insists that the toxæmia has got in its work, as it always does, at the point of overstrain or injury or prolonged fatigue.

If one admits that in the cases so far mentioned there is a septic element, one is tempted to inquire whether this principle obtains in the realm of psychiatry. From an attack of the "blues" cured with a simple dose of calomel, one is led to view melancholia as an exaggerated "blue," but requiring more detailed anti-toxic or anti-bacterial remedies. No one treats insanity without consistent removal of intestinal bacterial products—in other words, without great attention to the daily evacuations. Like the epileptics, most cases of mental disorder present evidences of aspect, colour, odour, perverted secretions, etc., showing the presence of a toxæmic condition. The improvement of the mental condition moves *pari passu* with the improvement in all these matters. So convinced is Mr. White Robertson of this, that in the article above quoted he gives his opinion that all cases in mental hospitals should be thoroughly examined by X-rays and bismuth meals. The road to success in many of these conditions lies in a liberal dietary, which not only enables the weakened and poisoned nervous system to be renovated, but, stimulating nutrition generally, aids in removing toxins from the tissues—and, what is even more important, it prevents intestinal stasis by leaving a large residue which promotes efficient evacuations.

Many cases are known to the writer of melancholia with delusions which have been cured by a course of vaccines after other methods had failed. Two ladies who had had prolonged courses at Harrogate, amongst other therapeutic measures, were cured by the removal of their pyorrhœas by vaccines combined with local surgical measures. A case now under treatment has complete relief for nearly a fortnight after each inoculation, and the interval of relief is gradually lengthening. It is not for a moment contended that for such cases as these spa treatment is unsuitable. On the contrary, as the writer pointed out in his Presidential address in 1912 at the Balneological Section of the R.S.M., spa treatments are eminently useful in all septic conditions when administered in conformance with the principles of bacteriology. In the above cases the failure of the spa treatment was due to the measures being solely directed to the removal of toxins without efficiently removing the source of the supply in these cases of pyorrhœa. With cases of mania, it may be inquired why they often get well, and also why they often relapse. Text-books on mental diseases note the fact, but ignore the reason. Surely the explanation is the same? A patient recovers if—and only if—he can, with or without assistance, deal with the toxic cause, in just the same way as one recovers or not from an infectious fever. If that be so, how much more likely is recovery to take place should treatment be adopted in conformity with this principle?

The success of treatment by hypnotism and suggestion is in part due to the ease with which it cures constipation. All those who practise psychotherapy know that this part of the treatment can,

at any rate, be secured with reasonable certainty, and that it will be followed at once by such improvement in the general condition, that confidence in the method on the part of the patient and his friends will be early assured. So that here again by attacking a source of poisoning, benefit is gained. It is not often, however, though as in the two cases of mental depression alluded to, it was so, that the septic element constitutes the whole cause of the complaint. One may add another principle to the rules which should guide us in managing nervous disorders, *viz.*, "That in every case of nervous disease there may be a mental element," and that, "A diseased condition, if sustained long enough, produces a habit which is apt to remain long after the cause is removed." The habit is psychical, and the flaw is central, not necessarily peripheral. Many examples might be given. For instance, a man has a painful disease or injury of his leg. The limb is removed by amputation. But if the pain has lasted long enough, he does not lose his pain, but still feels it in the amputated part. Surgeons, in trying to cure this condition by further operations on the scar, know how unsatisfactory such operations are apt to be. Really such success as attends their efforts is due to suggestion, *i.e.*, to the strong expectation of relief on the part of the patient. Any practitioner of psycho-therapy knows he can obtain better results by suggestive methods. How otherwise explain the immediate cure of lameness with instant discarding of crutches, which attends the forcible movements of diseased joints to the sound of a brass band by travelling quacks? The explanation is that first a joint becomes painful. The patient finds that by fixing the joint by muscular action, the pain is relieved or removed. At first the least relaxation induces discomfort. This is experienced often enough to induce a mental habit, soon transferred from the conscious to the sub-conscious mind, by which the joint is kept fixed without the intervention of the conscious attention. The joint under this rest treatment becomes cured, but the fixation being now in the hands of the sub-conscious mind, remains. Suggestion is the means of dealing with the sub-conscious mind. All the paraphernalia of brass band, forcible movement, the pile of discarded crutches, the insistent assurance of relief, are but means of exciting the expectant attention necessary for cure. Cures of similar cases are effected in a less theatrical manner by medical practitioners every day, notably at the spas. There the balneo-therapeutic measures carried out create the mental atmosphere required to produce the necessary change in the sub-conscious mind. The frequency with which various neuralgias, headaches, tics, and other pains are removed by psycho-therapeutic means alone, proves that they were existing after the cause had gone.

Another principle should be mentioned—*viz.*, that in organic diseases of the nervous system the functional disturbance generally extends further than the direct influence of the organic lesion justifies. For instance, "in cases of apoplexy, the lesion acts on adjacent parts like shock, setting up functional disturbance." (Bernheim.) It is well known how a hemiplegic's powers may be improved months after the attack by exercises, and by methods of encouragement which in essence act on the principle of suggestion. We cannot make destroyed nerve elements anew, but we can call up activity in those which were only functionally out of gear. In fact we can remove the habit remaining after the cause has disappeared. Charcot was alluding to the same condition when he said that hysteria and disseminated sclerosis often existed together,

because he found that he could remove by suggestion many of the symptoms of this disease. The removable symptoms he considered as due to hysteria, though it is obvious that a "habit" acquired in a progressive period of the disease, reinforced as time goes on by auto-suggestion, constitutes the right explanation. Nicoll, in urging the use of hypnotism and suggestion in the treatment of organic nervous complaints, draws attention to the same point, using paralysis agitans as an example. He points out that patients suffering from this disease are unable to walk properly, or fall when they attempt to get about. One fall suffices to make the patient even more insecure and causes a want of confidence which soon becomes a habit, still further diminishing his powers of locomotion. The writer has observed the same thing in cases of locomotor ataxy. In one case a patient, well able to walk about, gave up after a fall all attempts to use his legs for ambulatory purposes. There are, then, sound reasons for using suggestion in organic nervous complaints. But there is more to be gained by this method of treatment than simple removal of the unnecessary mental concomitants of the disease. In many organic diseases the path of impulses from the centre to the periphery may be interrupted, but there are often alternative routes which are capable of adoption if only the necessary means be used. Suggestion offers a powerful but harmless means of doing this. Frankel's method of treating ataxia is an attempt to restore the voluntary co-ordination of certain movements by making special uses of the sense of sight. There is no question here of doing away with morbid anatomical changes in the spinal cord, but only of finding an alternative means. Lloyd Tuckey has observed the severe pains in a case of tabes dorsalis disappear under treatment by hypnotic suggestion, and the common experience of the relief of the pain of cancer by such means are all illustrations of the underlying principles, and urgently call for its more extended use in cases of organic disease.

What is here maintained is well illustrated in the case of epileptic attacks. Dr. Campbell Thomson, in his recent book on "Diseases of the Nervous System," says many patients find out for themselves that they can frequently ward off an attack by force of will, and that this power should be encouraged. He suggests that the moment a fit threatens, the patient should clench his teeth and grasp something tightly, preferably his own arm. He says that in many instances the discharge can in this way be avoided. Here is a good illustration of treatment by increasing the strength of the conscious mind, and also an illustration of an appeal to the sub-conscious. In no case would such treatment be successful in warding off a convulsion from a poisonous dose of strychnine administered for the first time. In epilepsy the centres have so frequently been stimulated by intestinal poisons that the mind learns the initial symptoms, and though the dose may not be able to cause an explosion when the conscious mind is strongly opposed, these symptoms cause an expectant attitude in the sub-conscious mind, which fires the mine. If this expectant attitude of the sub-conscious mind can be done away with or lessened by the means Dr. Thomson advises, the fit does not occur. How much more likely, then, is this line of treatment to be useful in epilepsy if the antitoxic treatment be combined with a systematic form of appeal to the sub-conscious mind in the method known as suggestion. In fact, this treatment is so well known to be of use that discussions have arisen as to how suggestion acts in these cases, and as to how best to use it. Some have thought that

the benefit arises only from the renovation of the nerve centres in the restful sleeps given by hypnosis. We hope enough has now been said to show that more than this is accomplished. In any case, the fact of its usefulness is undoubted.

Next to the cure of constipation, suggestion probably finds its most frequent opportunities in the cure of insomnia. In this complaint again, the habit is apt to remain long after the cause has gone. These are the cases *par excellence* for the psycho-therapist. Every such practitioner knows that these conditions are among the easiest with which he has to deal, and that in well-established cases suggestion offers possibilities which are not within the range of any drug treatment. There are many ways in which suggestion may be used for the cure of insomnia without the induction of hypnotic sleep. The writer's routine treatment is to explain to the patient the mechanism of normal sleep, to show how the habit has been broken, and to teach the patient how the habit of sleep may be recovered. This has been summed up for the patient in the following verse, which the patient has to mentally repeat while carrying out the plan:—

"First I must get quite comfy,
Limbs all relaxed and free;
Breathing so calmly, deeply,
Sleep's stealing over me.
Drowsy—so drowsy—drifting
Down into slumber deep,
I feel I am really going—
Going—going—to sleep."

By this method not only is the patient's attention kept from wandering, but a strong auto-suggestion is added. It very rarely fails.

The writer's intention is not here to teach the practice of suggestion, but only to make out a plea for its more systematic use. When attending the discussions which have been taking place recently in London on the nervous conditions produced by the war, one could not but be struck with the almost universal want of knowledge of the practice of suggestion exhibited by the members at the meetings, more especially on the part of those who were most averse to this treatment. This, however, is not to be wondered at when one reflects that England is almost the only country in Europe which has no school for the treatment of hypnotism and suggestion, and no hospital systematically devoted to its use and instruction. Even the physicians who specialise in psycho-therapy seem to have educated their natural gifts in a haphazard manner, and from their remarks it is obvious that their acquaintance with the ordinary text-books is very limited. Here when, owing to the war, there are such numbers of persons requiring this special form of therapeutics (which is supplied by all other combatant nations to their armies) there is an urgent need for the establishment of such an institution.

In conclusion, then, the object of this paper will be attained, firstly, if it be successful in directing more general attention to the septic element present in so many diseased nervous conditions, and especially in obtaining recognition of the work of Drs. Orr and Rows in this connection; secondly, in securing assent to the existence of certain principles which govern the mental side of nerve disorders; and, thirdly, if it helps in the establishment in this country of a school for the study and teaching of psycho-therapeutics, and notably of that branch known under the terms of hypnotism and suggestion.

ON TALKING.

By A. WITHERS GREEN.

TALKING is a lost art! Our hurried life, our commercial view of life, have helped to make it so. The greed of the dollar may add to the quantity and rapidity of talk, but debases its quality, making of it almost a machine product. Since we must be ever using speech, can we not deliver it from base uses and enthrone it, as it is, a gift to humanity?

We had better begin in private and humble spheres, domestic elegance in speech, as well as in furniture and economy. We are told that the tongue is an unruly member—the more then let us watch its doings, and direct its power into wise channels. Since talking is the commonest production of intelligent sounds, it should become the most perfected, not only in utility, but in charm. If the speaker has a musical ear, he will order his voice to please his ear, and his utterances will become musical too. There will be a harmonious compact between tongue and ear to judge and arrange the sounds produced.

Talking when stepping out into the publicity of the filled drawing room or public building assumes an altered form, viz., that of reading. Wouldst thou be a good reader? First learn to talk well. Many of the best speeches are talked out aloud in the study before they thrill the assembled crowd. Speechifying is akin to reading—you follow copied out statements, or you give forth aloud your own prepared thoughts. In both cases there is the element of preparation. Talking implies that you are unprepared. You don't know what the topic is to be. Hence it is that a well read, and observant, ear-open, eye-open, all-senses-open man has one element which makes for a good talker, and that factor is *knowledge*.

Among the many titles bestowed on the late Dr. Samuel Johnson, as you may read on the stone which bears his dwarf statue, at the east end of St. Clement Danes Churchyard in the Strand, is that of "talker," coming last, but not least, his biographer would declare. Now be it noted that Johnson was described by those who knew him as a panjandrum of literature, and also a library in himself. At the same time Garrick described him as the first man for sprightly conversation, which savoured most of the facts of human life.

To become a good talker one essential I have already mentioned is knowledge, and especially first-hand knowledge, and knowledge gained by experience; hence youth does not provide the best talkers, nor does loquacious old age, which, when disordered is apt to be mingled with knowledge. True it is that this lack of order is the bane of conversation—when one subject is talked upon but for five minutes, another comes clashing in, followed suddenly by a third topic. Alas! who can enjoy such confusion of diverse associations? A liberal education with a liberal use of it, issuing out in speech supplies a *command of words*—words right in themselves, words timely uttered, words choicely combined, freedom of speech, yet wholly controlled by the collegiate or self-educated mind.

Every theme, whether written or spoken, falls like lead unless upborne on the wings of imagination. That which nearly, but did not actually happen, let it be brought to the surface. Pregnant

possibility is surely a probability, and would have occurred, but for some unforeseen circumstances.

Imagination is like the punkah in the East. The Sahib is oppressed—the heat is unbearable. Why? The punkah man has fallen asleep. The punkah no longer fans the air. Imagination! Arise and spread thine imagery throughout the atmosphere of my even inanimate surroundings, and I can talk myself and friend out of any vile temper.

Talking or in silence, let us be ourselves. It has been recorded of Thomas Carlyle and a friend that they sat together for a considerable time and then parted, neither having spoken on any theme at all, but they agreed nevertheless that they had had a fine time together. They were both great thinkers, and may have both been occupied with their own thoughts, and so really needed no social disturbances. This may be quoted as an exception, for one usually visits a friend either to say something to him or else to hear something from him.

If we talk of current events, more or less known to all, we should be at ease. If we light up thoughts on any common or private hobby, we then too should not lose our presence of mind. This last named is a most important element. Having this mental equilibrium we are ourselves, we are not self-conscious, we are free to sparkle mentally and catch flashes from others. What a delightful theme for intercourse is a hobby, be it books or golf, but the latter or any single one must not play the tyrant. Short sighted and fatally introspective is the man who has no hobby. What a pleasant way of filling up the gaps in one's knowledge! Suddenly you hear the very bit you wanted to know, whether mentioned inadvertently, or in reply to a question.

The power of speech can be a very potent weapon in the hand of the physician anxious to be of real service to the one who comes to him seeking alleviation from ill-health. We have heard of some advertised as very clever, who say little, look serious, act strangely, dogmatise precipitately, but this nature is unnatural and fills but a small space. No! Separated from the muteness or the limited scale of the brute creation, let us welcome with reverence, knowledge, and control the fair gift of speech, including that commonest use, the social chat. I have often noticed, especially at the after-dinner stage, that the time is occupied by tales of a questionable character—one is started, to be capped by another decidedly inferior in good taste, and perchance by a third so base, perhaps even insulting to the Deity. At such times I have wished myself out of the scene. A programme is useful, though inelastic, and refining is the presence of the fair sex as part of the company.

Our talking needs to be elevated, socially it often degrades us. The home life helps, and intermingled life also should have its high ideals and lofty aims. There is need of reform in order that we may talk to profitable and abiding pleasure.

So much is found in print that we let the printed page talk to us, but surely the silent letters look to us to wing them with life, and to sound out their excellencies along with our daily talk. The daily paper, the weekly gazette, and monthly journal, all should be the handmaids of our voice and speech.

SIR H. E. ROSCOE, F.R.S., left estate valued at £44,871.

MR. WALTER NICOL, of Darlington, left £1,000 to the Hartlepool Hospital.

MAJOR WALTER HARRY NICHOLS, J.P. of Cork, left £250 each to the Eve, Ear and Throat Hospital, Cork and the Southern Infirmary, Cork.

NOTES OF A CASE OF CHYLURIA.*

By JAMES ALEXANDER LINDSAY,
M.D., F.R.C.P.,

Professor of Medicine in the Queen's University of Belfast;
President of the Section of Medicine of the Royal
Academy of Medicine in Ireland.

CHYLURIA, dependent on the presence of the filaria bancrofti, is a common endemic disease in various parts of the world—China, Japan, Egypt, Zanzibar, Mauritius, some parts of Australia, Brazil, the Southern States of America, and Bermuda. The organism is a very thin nematode worm, three or four inches in length, and the female produces an immense number of embryos, about the ninetieth part of an inch in length, and the diameter of a red blood corpuscle in thickness. They enter the blood current by the lymphatics. They are almost or entirely absent in the daytime, but usually present in large numbers at night. In chyluria they are probably situated in the main branches of the thoracic duct, causing a stasis of the lymph in the lymphatics of the bladder or perhaps of the pelvis of the kidney.

All observers are, however, agreed that chyluria also occurs in a sporadic, non-parasitic form, that it is observed occasionally in the British Islands in persons who have never been abroad, and in whom infection of the filaria bancrofti can be definitely excluded. These cases are very rare. Herringham, whose account of the subject is the best that I have met, records that at St. Bartholomew's Hospital a case occurred in 1898, and no second case until the year 1910. No case has occurred in my time at the Royal Victoria Hospital, Belfast. The literature of the subject is singularly scanty. Text-books are very reticent on the subject, and some of them ignore it altogether. Very few *post mortem* records are available. It seems, therefore, desirable to put on record the notes of a case at present under my observation.

The patient is a clergyman, a man of tall stature and robust physique, weighing over 13 stones. He is a man of exceptional, almost morbid, energy. He ministers to two country churches, is fond of shooting and cycling, and often engages in manual labour both about his house and in the fields. He is, as the phrase is, "always on the go," and has difficulty in using up his exceptional stores of force.

He consulted me for the first time in April, 1913. He gave a history of excellent health until recent times. He had never been abroad. He had always been a strenuous worker, and had taken no holiday for six years. He was operated on in 1909 for congenital hernia. In August, 1910, he began to notice certain peculiar characters in his urine. It was milky in appearance. In the chamber it was sometimes dark brown, probably due to the presence of blood, but usually it was white as chalk. He noticed the curious fact that the dog or the cat would lap it up if permitted to do so. At first these appearances were only occasional, but after a time they occurred nearly every morning between 4 o'clock and 6 o'clock. During the day the urine usually appeared to be normal, but if he lay down in the afternoon, or partook of a hearty meal containing much fat, the milky characters recurred. He had the impression that fatigue, full meals, or mental worry precipitated or aggravated the attacks. He complained, also, of a tired feeling in the lumbar region, and of a desire to micturate rather frequently. On four or five occasions he had a stoppage of his urine, but after some hours of discomfort he passed with pain one or two stringy lumps, and then the urine flowed freely. He had noticed that if he did not go to bed until five or

six hours after the last meal there was no unusual appearance in the urine during the night. He was accustomed to sleep on his back. His general health was unimpaired.

Examination of the patient was negative. He was a fine specimen of vigorous manhood, and all the organs seemed healthy. There was no abnormality to be detected in the genital organs.

The urine was milky in appearance and faintly acid in reaction. An examination at the Pathological Laboratory of the Queen's University revealed the presence of large quantities of chyle, but no other abnormality. No organisms were discovered.

My advice to the patient was to put some limit to his excessive activities; to exercise strict moderation in diet, especially as regards fatty foods, and to take precaution against lying on his back. A tonic was ordered.

The patient consulted me a second time on July 2nd, 1913, *i.e.*, after an interval of nearly three months. He reported improvement, the chyluria being now intermittent and the general condition good.

I did not see him again until January 13th, 1916, when he came to introduce another patient to me. He reported himself as nearly well, the chyluria being now only occasional, and occurring only in consequence of some exciting cause. Much fatigue or a heavy evening meal will sometimes cause a recurrence of his symptoms. He has adopted a mechanical contrivance to prevent him from sleeping on his back.

The pathology of these cases is obscure. Two possible theories might be suggested, *viz.*: That there is some actual communication between the lymphatics and the urinary passages, or that, as in the analogous case of the lipuria of diabetes, the condition of the urine depends upon some failure of assimilation. *Post mortem* records are very meagre, and throw no decisive light upon the condition. The clinical evidence is somewhat conflicting. In some cases the chylous urine occurs only after meals; in others, such as the present case, chiefly at night. It is to be noted that in my case if the patient took an afternoon sleep he was prone to have an attack. There is evidence that fatigue and full meals have a tendency to cause the appearance of chyle in the urine. A case is on record where lying on the right side prevented attacks. In another case attacks occurred only when the patient was in the erect position. Cases have been known to undergo arrest without assignable cause.

The prognosis is not unfavourable. Most cases last for many years, and do not seem to interfere seriously with the general health. It is noteworthy that wasting and progressive cachexia are hardly ever reported. There are no known consequences or complications.

The treatment of so rare a disease, and one of which the normal course is so obscure, is naturally unsatisfactory. There is no clear proof that any drug has any decisive influence. Iodide of potash has been recommended. Stephen Mackenzie advised a combination of sodium benzoate, gallic acid and tincture of iron. Gallic acid is recommended by other observers. Antiseptics seem without effect. Tonics have been given on general lines.

The improvement in my patient seems to have depended upon limitation of his excessive activities, moderation in diet, and precautions against sleeping on the back.

A GIFT of £3,000. to endow a ward to be named the Reginald Hirst Ward, has been made to Huddersfield Royal Infirmary by Mrs. Kate Edith Hirst, of Kirkburton, in memory of her husband.

* Read before the Section of Medicine in the Royal Academy of Medicine in Ireland, on Friday, February 4th, 1916.

THE RELATION OF PROGNOSTIC FACTORS TO TREATMENT IN DIABETES MELLITUS.

By NELLIS B. FOSTER, M.D.,
New York.

WE are not in the habit of considering those factors which influence prognosis as intimately related to the problem of therapeutics. The reason we do not do so is because we customarily think in the terms of acute disease. The necessity of considering prognostic factors therapeutically is self-evident. When a man suffering from chronic renal disease is advised to seek a mild winter climate the physician is trying to avoid the danger to his patient from pneumonia. He considers a prognostic factor as a problem in preventive therapeutics. He may not ponder, but he knows that of individuals with chronic disease only a minority die of that disease—the majority, weakened and undermined in health, die of acute superimposed infections or of complications. The apt formula of a famous American physician on how to live to old age is pat: "Acquire a chronic disease and take care of yourself."

If, then, we are to advise intelligently patients with maladies such as chronic nephritis and diabetes, we must form a very clear estimate in each case as to just what the dangers are which menace his existence. This is necessary in order to carry out the prime endeavour of prolonging life—and it is no less requisite that we consider these factors in the means adopted to ameliorate the symptoms of the disease. The two goals of therapeutic endeavour—prolongation of life and the amelioration of symptoms, are secured but seldom by a change in the individual; not infrequently by a change in the environmental demand. Therapy directed to ætiological factors is at present almost unknown in the realm of chronic disease.

These principles find no better example than in the treatment of patients with diabetes mellitus. With this disease, perhaps more than with any other, the afflicted is out of joint with his environment; he can no longer eat or work with his brother man. We are apt not to think of it, but the condition is appalling. Every single human privilege is walled off by an adaptation to a narrowed function.

Now what are the dangers which beset the existence of the patient with diabetes? Numerically, infections take first rank and account, directly or indirectly, by precipitating coma for over 78 per cent. of the deaths. Elsewhere (a) I have called attention to the frequency of surgical infections, but I do not wish at present to limit my remarks to any one type. Even a slight cold becomes a very serious complication with a diabetic child; tonsillitis that would hardly confine a healthy man to the house has sent many diabetics to the grave. Tuberculosis is proverbially common among diabetics seen in hospital practice, less so among the well-to-do. Pneumonia, in my experience, has been invariably fatal, often because it precipitates acidosis and coma. Since these dangers which kill the majority of diabetics menace all alike, any mode of treatment which disregards these prognostic factors is lacking in foresight. Once contracted, infections are difficult in any case to combat, and often the fight is hopeless; the only safety is in keeping the patient in some condition approximating to normal vigour, so that infective agents find a less fertile soil. This principle concerning infections, as related to bodily vigour, is established, and finds no exception in the realm of chronic disease. Disregard of one ultimate aim of therapy in diabetes—

namely, an approach towards a healthy state of resistance to infectious disease, so often leads to calamity that I am frankly pessimistic for that group of cases that can attain and preserve a sugar-free urine only at the expense of nutrition. With a sufficient number of cases it will, I think, be manifest that one danger has been exchanged for another.

There is no question in my opinion that the *average* diabetic not only has more comfort and sense of well-being when his urine contains no sugar, but that his actual resistance to infection is higher. I refer now to cases in middle life in which a severe glycosuria is not complicated by acidosis, and in which under-nutrition and loss of strength are the striking features. The majority of these cases regain strength and energy after the glycosuria is controlled. With others the diet which controls the glycosuria necessitates that the patient remain some 20 per cent. under normal weight, while with a diet which holds him but 10 per cent. under weight he has about fifteen grams of sugar daily in the urine. Now, which is the preferable condition? Neunyn said that he did not know, and I doubt if we do at present. Again, exercise benefits the majority, but some patients have slight rises in temperature after exercise, and without the exercise the tolerance is too low for safety. It seems to me that here we have questions not related to our ideals of treatment, but intimately concerned with the future of our patient, and they are best decided by remembering from what direction danger approaches.

As to whether a sugar-free urine indicates a state of affairs in the body economy which may be spoken of as holding the diabetic tendency in control, I have some doubts. There are facts which speak against it—as, for example, the frequency of pathological organic changes which develop after long periods during which the diabetes is apparently under full control. I refer to renal disease in the younger patients and nerve lesions in all. As a matter of fact, we are not able to effect the end we strive for. As proof that we are not overtaxing the body's powers to handle sugar, we customarily accept the fact that the urine does not contain glucose. But this is not the criterion. The real criterion is the percentage of blood sugar; and with any cases other than the mild ones the blood sugar remains above normal, and can be reduced to normal only during periods of excessively low diet or absolute fasting. In other words, there is a considerable margin between the maximal normal (0.14 per cent.) of blood sugar concentration and the threshold of renal permeability (0.16 to 0.17 per cent.); constant hyperglycæmia means a continuation of an abnormal state. We can successfully remove the overload, it is true, when we reduce the blood sugar from 0.35 or 0.45 per cent. down to 0.16 or 0.17 per cent., and with the majority of patients that reduction effects a wonderful change in general health. But 0.16 per cent. is not a normal blood sugar. The blood then, and not the urine, is the measure of whether the means we employ are suitable. With some of the severest and most hopeless cases that have come under my observation the urine contained no sugar at a time when the blood sugar, due to a concomitant kidney disease, was as much as three times the normal. Evidently the urine may mean nothing as to the diabetic state.

To excessive hyperglycæmia is, in my opinion, to be assigned a large degree of impairment of function, and this idea I can best make clear by an analogy drawn from chronic nephritis. It is a common observation that with these cases of chronic renal disease at periods before treatment, all the tests and the metabolism studies may indi-

(a) "Diabetes Mellitus." Philadelphia. 1915.

cate a hopeless degree of renal damage, the urea of the blood may be very high, and the phthalein excretion reduced to traces. After an appropriate regimen the same tests indicate a clear-cut increase in the ability of the kidney to perform its function. This phenomenon we may style a depression of function due to the overload. With diabetes the state of affairs is not very different. At times when there is marked hyperglycæmia the tolerance appears nil; after a couple of months of treatment, when the blood sugar is reduced to only a little over normal, there is often a surprising ability to use carbohydrate. For this reason I think it is impossible to tell in advance whether any given case is mild or severe. Many that seem severe in the beginning, even with considerable acidosis, prove after a year to be only mild. But this is true only when the disease is not of long duration. With cases in which the indications are that a year or two at most have passed before treatment is commenced, my results have been very encouraging when the patients could do what their disease demanded. For this reason I shall divide my cases into two groups—early and advanced. The severity of the acidosis or glycosuria with these cases in the beginning was no criterion of the actual conditions, and this is adequately demonstrated by cases that were infused at the commencement of treatment because of incipient coma. The history with these cases indicated about a year's duration of the diabetes. Some of these individuals are now using, on five days of the week, unrestricted amounts of starch without resultant glycosuria. One of them has a normal blood sugar, unless the routine vegetable day be omitted for several weeks. All are young, under thirty-five years, and all are up to normal weight and vigour. These and other cases I have studied illustrate the difficulty stated by Joslin in differentiating mild from severe diabetes. I know an old gentleman who was a severe diabetic at the age of twenty-two years. He is now nearly seventy, and has had no glycosuria for forty years. He was a patient of the elder Shattuck. In fact, I question whether the terms mean just what we wish to express when we speak of young patients with glycosuria and severe acidosis. Should we not rather say early and advanced? (The older cases are in a class by themselves in which acidosis is but seldom of moment, even when of considerable degree, as Neunyn pointed out.) My experience of the last five years has been that with young adults who came under observation early after the disease was recognised, all have secured sugar-free urines, notwithstanding severe acidosis at the start, and all who followed advice have recovered a considerable degree of tolerance for carbohydrate, much above what it was in the beginning of treatment.

Concerning the cases of young adults, four to five years of age, who were observed first when the disease was of some years' duration—that is, advanced cases—the results have not been encouraging, even when, as often happened, on account of but slight acidosis, it appeared in the beginning that the task was much easier than with some of the early cases. The glycosuria may be easily controlled, but the blood sugar is difficult to reduce to normal, and it remains normal only under the most restricted conditions. As a rule, the tolerance secured is too meagre to preserve health over long periods. My observation indicates that with this group those patients who have adhered to diet have died of complications and infections wherein coma occurred only as a sequel to acute disease—i.e., pneumonia or *la grippe*. Of those who have not been so rigidly dieted or who have not observed diet with due care the majority have died in coma. The period of life in both groups averages over two years from the beginning of the treatment. An

estimate of value of treatment as measured in years of life can be discovered only by a very large number of cases observed for years. The point is that with advanced cases in young persons the results are discouraging even when the disease is apparently under control. And I might add here that this statement applies also to diabetic children. Cases now living that have been for several years ideal, so far as absence of glycosuria indicates, are under height, under-nourished, and altogether most pathetic.

One interpretation of these facts as I understand them is this: That with early cases we can expect much from treatment. Vigilant control of the diet so that glycosuria is absent and the blood sugar down to nearly normal is justified, since with time tolerance increases. Even a dangerous degree of acidosis does not necessarily frustrate this design. This interpretation rests on the hypothesis that I have stated earlier in the paper—namely, that the hyperglycæmia itself induces pathological function. The alternative interpretation is that these early cases that are now doing well will eventually deteriorate and become the typical advanced case. It will take years to decide this point, but against this contention is the increased tolerance for carbohydrates observed as years go by. It is to be remembered, however, that some young adults with severe diabetes and considerable acidosis live six to ten years under the less stringent methods which aim only to keep sugar excretion low, but never abolish it completely. But it is my belief that with those cases in which the diagnosis is made early much can be accomplished by vigorous treatment. It matters not whether the blood sugar be reduced by the rapid method of complete fasting or by the slower method of periodic fasts; the end that must be attained is a sugar-free urine, blood sugar as near normal as possible, and an absence of acidosis.

The chief danger lies in the after period, when, because the urine is so persistently normal, patients, and even physicians, are led to doubt the necessity of the diet, with consequences that are sometimes serious. With young patients, early or advanced, the danger to be feared is acidosis, and our therapeutic endeavours are directed to prevent its development or abolish it after development. When there is no acidosis I have never been compelled to resort to fast days as a means of controlling the most extreme glycosuria, although there is no doubt the end can be attained most rapidly by the complete withdrawal of food. The question is, then, is starvation always safe? It has been generally believed, and was emphatically stated by Neunyn, that an acidosis tendency once established is prone to recur. With diabetics as with normal persons, starvation induces acidosis, and even this. I think, can and should be avoided, since one cannot tell where it may lead. Cases that I have seen in consultation have made me more definite in this impression. In two recent instances an alarming acidosis, initiated by fasting, necessitated heroic measures which availed to save the life of only one patient. These unfortunate issues we are not at present able to prevent, unless the patient be in a hospital, and adequate warning of danger be watched for in the laboratory studies.

Turning now to cases in which acidosis dominates the picture, and in which the disease is of long duration, the therapeutic problem is again different. The menace here is coma, and the fact that any of the patients can be relieved of their danger, even for a brief time, by fasting is a remarkable contribution to our knowledge of diabetes. With cases that are in imminent danger of coma, in which each day may be the last, a measure that promises any success at all is of the greatest value; and here, I

believe, is the special field for the fasting method. That fasting in itself may be a dangerous procedure, we recognise; as are also serious surgical measures. There are occasions when we have scant choice. That the fasting treatment is not devoid of hazard we must recognise, and it throws upon us the responsibility to use this method only when other and less drastic methods are inadequate to effect the desired result; and to recognise that fasting is, again, like many surgical measures, suited best for use in well equipped hospitals, in which careful observation and frequent tests of blood, urine, and alveolar air are made as part of the routine. Only in this way can dangerous reactions be foreseen and requisite measures be instituted. The treatment is fundamentally a treatment for grave acidosis.

Finally, then, I can summarise my conclusions: Every case of diabetes demands the most careful study not only of the diabetic state, but also of all conditions which may influence the future health of the patient. Infections must be kept in mind as the constant danger. Early cases must be kept free of glycosuria in order to raise resistance and to avoid the development of acidosis. This can be done even in face of acidosis by the use of restricted low diets. With advanced cases glycosuria must be controlled in order to regain normal weight and vigour. When there is grave acidosis this also can now with many cases be successfully abolished. The chief difficulty in treating all diabetics is the necessity of constant vigilance over years.

THE CORRELATION BETWEEN OLFACTORY AND GENITAL FUNCTIONS IN THE HUMAN FEMALE.

By J. A. HAGEMANN, M.D.,

Pittsburgh, Pennsylvania.

THE existence of a correlation between certain intranasal tissues and the generative organs has long been a matter of universal medical knowledge. Perhaps the qualifying term "medical" is too limiting, for to many of the laity as well it is known that such an alliance exists. Althaus ("Beitrag zur Physiolog. und Pathol. des Olfactorius") speaks of the mutual attraction of animals of opposite sexes for each other by olfactory perception of distinct odours at the period of rutting.

The symptomatology so far as it pertains to the male sex will intentionally be disregarded in this paper. In April, 1884, Dr. J. N. Mackenzie, in the *American Journal of the Medical Sciences*, published some physiological and clinical observations which he had made, and stated that "in certain women with normal olfactory organs regularly with menstruation a swelling of the erectile tissue of the nose occurs, that menstruation is at times replaced by epistaxis, and stimulation of the genital tracts is occasioned by affections of the nasal organs."

It remained, however, for Fliess, of Germany, to amend the imperfect knowledge which then prevailed regarding the dependency between certain functions of the nose and those of the female procreative organs. In 1887 he published a paper on "The Relation of the Nose and Female Genitalia," in which he affirmed that certain "genital spots" could be determined in the nasal mucous membrane, and that the anæsthesiation of these spots by the local application of cocaine would in many cases result in relief from the agonising pain of dysmenorrhœa, provided the same was not due to an obstruction of the cervix. The spots designated are the tubercle of the septum and the anterior part of the inferior turbinate. Later, Fliess had recourse to employment of the galvanocautery or tri-

chloracetic acid in an attempt to lend permanence to the transitory palliation which cocaine bestowed. His postulate excited animated discussion throughout Europe. Kuttner criticised Fliess' theories unsparingly, pertinently asserting that it was unreasonable to admit that a controlling spot located in the nose, should surpass and supersede any cerebral or spinal centre. Many other European authorities also entered the lists for and against Fliess' assumptions.

His latest brochure consists essentially of a reiteration of his tenets, an arraignment of his detractors, and an augmentation of his theoretical intranasal genital centres by the addition of another centre dominating the abdominal pains experienced by self-polluting girls. After stating that the primary changes in the nasal genital spots are frequently of an infectious nature, and admitting that these changes are not the sole solution of the distal manifestations (dysmenorrhœa), he adds that "the anatomy of this neuralgic conversion is as unsolved as the nature of the structural change, for example, in neuralgia of the trigeminus or ischiatic nerve." In essaying to substantiate his postulate by producing evidence of anatomical relationship, Fliess says: "In the nose the erectile bodies are under control of the sphenopalatine ganglion, which receives sympathetic fibres from the carotid plexus through the petrosus profundus nerve. There would thus be an anatomical path to the sympathetic, which controls the sexual functions as well."

In the absence of an affiliation with a gynecological clinic, the writer has not had adequate opportunity afforded to verify or confute, to his own conviction, the conclusions of Fliess; but nasal phenomena analogous to, yet differing from those described by him, have been encountered by me a number of times. The specification of these phenomena and their interpretation is the *raison d'être* of this paper.

It may not be amiss to interpose here, by way of premise, a compend of some of the more relevant præcognita.

The olfactory sense indubitably exercised a paramount influence in the survival and development of the primæval zoological forms which were wafted to and fro by the waters of the "vasty deep" in the earliest faunal geneses. The low forms of animal life which had progressed beyond the amœbic stage, and in which there had been evolved an incipient tactile sense, would in the prevailing course of events gradually develop a discriminating faculty which would, at an early period, subserve the selecting of nourishing, and later of savoury food. Coeval with this development there would be revealed the earliest traces of sexual evolvment, for sustentation and propagation in binary, rudimentary form, constituted exclusively the functions possessed by these primitive embodiments of animal life. One can readily realise that in this elementary stage of evolution through which the primal forms of life were passing, there could be no great development of a selective faculty.

It is, however, conjectural that a mere specific sense, if any, developing gradatim from the rudimentary tactile perceptivity, would be in the nature of an olfactory faculty. In other words, as the incalculable successive generations of animalcules became more highly organised, a capacity to choose palatable food and perceive a conjugal mate must imperceptibly, but unintermittently have become established; so that, by slow degrees, the nascent organisms became both sensory and sensuous. If we pass over a diuturnity and study animals high in the scale of evolution we encounter the culminating degree of this development. To review even cursorily the interminable intermediate trans-

itional forms would be a stupendous task. Let it suffice to say that this binate faculty, so common in primary forms, is retained by many that have progressed sufficiently no longer to require either or both capabilities in the struggle for existence. The males of a considerable number of mammals possess odoriferous secreting glands, which in various species are situated in different parts of the body. In certain ones the odour becomes more evident during the breeding season. It is confirmed that the females of these several species, during the rutting season, lustily exercise their olfactory endowment while experiencing a disposition to associate with the males. The consequent hyperæmia of the olfactory area conformably produces tumescence and hypersecretion in this section of the nose. It seems idle to seek an anatomically linked bond, via the nervous system, between the olfactory and conjugal functions, for these developed contemporaneously, in multiform alliances among low as well as higher forms of life, according to the several requirements of the respective organisms.

If we contemplate that the perception of savoury odours "makes the mouth water," that hearing a patriotic air may produce profuse lachrymation, that the witnessing of a touching scene may cause a "lump in the throat," all involuntary and presumably irrelevant sequences, we realise the futility of speculating upon an anatomical vinculum. It is more to the purpose for us to keep in mind that some brain centres apparently perform dual offices, or that two centres controlling different faculties act in unison in response to a stimulus from either of the distal areas whose functions they control. In the example under discussion, a sexual incitement may give rise to swelling of erectile bodies in the olfactory region; or, conversely, certain odours perceived by the olfactory nerves may set up hyperæmia in the genital organs. Moreover, in some forms a concordant execution of both functions is probably habitual.

When pondering the foregoing data it does not seem extravagant to propound the paradoxical theory that the olfactory excitation which occurs in some young women may be regarded as one expression of atavism. These residual nerve-functions, remainders of once active and essential faculties possessed by our ancestors, are now latent and dormant, and have long, long ago ceased to be proficuous. However, eradication of a dispensable function is consummated only after interminable periods of time, and irregularly there occurs a vestigial resurgence of one or another feature of atavism.

If one keeps in mind the foregoing postulate while scanning the following summary, an apparent corroboration of the theory above advanced is marked. Where an unequivocal correlation between nasal and genital functions exists, the pain and tumescence are found chiefly near the anterior portion of the middle turbinate and the section of the septum diametrically opposite and above this point. The turgescence observed in the lower part of the nose is probably due to continuity of the connective tissue by reason of which translocation of the fluids takes place from above.

Reduction, by cocaine and adrenalin, of the turgescence over the inferior turbinates in two salient nasogenital cases did not notably alleviate the distressing pain and sensation of pressure which was complained of at the portion of the nose between the eyes, whereas application of the same solution to the olfactory field afforded prompt, but only transitory, relief.

Bilateral œdema of upper and lower eyelids that had manifest genital dependency twice subsided

within a few hours after application of cocaine and adrenalin solution to the olfactory field. In this instance there evidently was a dehiscence in the laminae papyraceæ, permitting a "damming out" of the fluids which the limited space within the nose could not contain.

Surgical treatment by means of inferior turbinotomy or turbinectomy, will, in a disconcerting number of cases, fail to benefit the class under discussion, whereas removal of the anterior half of the middle turbinate, supplemented, if necessary, by a submucous resection of the septum, secures permanent deliverance from the recurrent attacks. His clinical observations, differing in several respects from some published by other writers, and his deductions, arrived at from disparate premises, are the writer's plea in justification of this paper.

CLINICAL RECORDS.

FRACTURE OF THE FIRST RIGHT RIB.

By THOMAS P. CODD, L.R.C.P. AND S.I.

As this is a very rare accident I thought it of interest to report a case. A lady about 45 years of age received personal injuries in a collision between two vehicles. She complained of a pain on movement of the right arm. There was a swelling over the right breast, not at the site of fracture. The swelling was painful on examination, she had flying pains across the chest, under the right shoulder joint, and up and down the back. There was no deformity about the clavicle, and the fracture was in good position, which would be expected, considering the association this rib has with muscles and ligaments. Sir Thomas Myles consulted with me in the case. He suggested the X-rays, which revealed this most difficult injury to diagnose. As this rib is so closely related to important blood-vessels, it is surprising that there was not a rupture of some of the principal vessels, and death from hæmorrhage, or later on the formation of an aneurysm, as it is so near the aorta. The patient is doing well, only complaining of a pain down the arm occasionally and effect of shock to the nerves.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

MIDDLE EAR DISEASE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to the letters in your issues of January 26th and February 23rd, I would suggest that many cases of inflamed middle ear are due not so much to simple extension from the nasopharyngeal end of the Eustachian tube as to the blowing of infected mucus up that passage. During an acute or subacute nasal and nasopharyngeal catarrh, when there is discomfort in the ears, and even when there is not, people are apt to blow the nose forcibly to get temporary relief. They should be warned to blow only gently, and to avoid compressing the nostrils at the beginning of the act. It may be feared, too, that by some practitioners Politzer's inflation is done at such times without consideration of this possible consequence.

I am, Sir, yours truly,

M. D. J.

London, N.W.,

February 26th, 1916.

THE LATE PRINCIPAL SIR WM. TURNER.
To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your appreciation of the late Principal of Edinburgh University will be read with interest by old Edinburgh men all over the world. I have not seen, in any obituary notice, reference to one of Turner's marked characteristics—viz., his power of discipline. A large class of second year medical students is not easy to handle. Turner kept perfect order without having to expostulate or correct. He did so entirely by the power of his eye. He only looked, and the offender felt "squashed." In this respect, Turner resembled his old colleague, the late Professor P. G. Tait.

I am, Sir, yours truly,
 RADIUS.

THE CENTRAL MEDICAL WAR COMMITTEE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The *Evening Standard* of February 21st refers to the above body as a "representative committee of the medical profession." It cannot be too widely known that this Committee has no authority to speak or act for the profession. It is self-appointed, and its energies at present appear to be directed to "jumping" medical men into military service. The B.M.A., from which this precious coterie springs, evidently learned something from the Insurance Bill tactics of Mr. Lloyd George.

I am, Sir, yours truly,
 BATON.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

MEETING HELD FRIDAY, JANUARY 7TH, 1916.

The President, W. A. WINTER, M.D., in the Chair.

PHYSICALLY DEFECTIVE CHILDREN AND THE PROBLEM OF THEIR EDUCATION.

THE PRESIDENT gave an address on the above subject, which was printed in THE MEDICAL PRESS AND CIRCULAR of February 9th.

Dr. KIRKPATRICK drew attention to the success of the school held in connection with the Orthopædic Hospital, Dublin. The teaching of the children there had proved of benefit, not only to the education of the children, but also to their medical treatment.

CERTIFICATION OF INSURED PERSONS IN IRELAND.

Dr. ROWLETTE read a paper on this subject which was printed in THE MEDICAL PRESS AND CIRCULAR of February 23rd.

Dr. MAURICE HAYES pointed out the importance of the principle that none but the medical attendant should be required to certify for his own patients.

Dr. HENNESSY called attention to the great importance of the ethical triumph which the profession had attained in the recent decisions of the Irish Insurance Commissioners.

Mrs. ELLEN CONSTANCE SOAMES, of Porchester-terrace, widow of Captain Henry Soames, R.A., gave £100 each to the Children's Hospital, Northcourt, Hampstead, and the Disabled Soldiers' and Sailors' Help Society.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

MEETING HELD FRIDAY, JANUARY 14TH, 1916.

DR. T. P. C. KIRKPATRICK in the Chair.

OSSIFICATION OF THE THORACIC VERTEBRÆ IN MAN.

PROFESSOR A. FRANCIS DIXON read a short note on the above. He showed that the epiphyseal plates which appear on the upper and lower aspects of these vertebræ extend on to the lateral aspects of the bodies so as to give rise to the articular facets for the heads of the ribs. In this particular, the epiphyseal plates in man, although they in other ways appear to be vestigial, conformed to the arrangement which obtains in lower animals. A number of specimens from the human subject were exhibited, and also several from various forms of lower animals. A striking agreement, as regards the ossification of the costal facets, was demonstrated to exist in the various forms, including man.

Dr. HOLTBY referred to the fact shown in Professor Dixon's specimens that the costal articular facets seemed to be losing their connection with the epiphyses.

THE HISTOLOGY OF THE PANCREAS OF A CAT, THE SUBJECT OF GLYCOSURIA.

Professor THOMPSON read a note on the above. Specimens were exhibited showing an apparent increase of islet tissue in many of the lobules. In others the islet cells had atrophied or wholly disappeared. On the whole the islet tissue seemed largely increased. It was difficult to bring this into harmony with the present theories of pancreatic diabetes, but the suggestion was made that possibly an increase of the anti-diabetic hormone might also disturb the function of the liver cell in regulating the processes of glycogenesis and glycogenolysis.

Professor METTAM mentioned the appearances found in the organs of a dog which had died of diabetes, where the islets of Langerhans were totally absent.

THE PELVIC COURSE OF THE DUCTUS DEFERENS.

Dr. HOLTBY read a preliminary note on the above, and referred to the fact that the ductus deferens showed, when the bladder was empty and contracted, a distinct kink in its course, this kink lying opposite the ischial spine, below and behind the ureter along the posterior margin of the paravesical shelf. In children at birth, the ductus showed two curvatures—one a transitory one where it crossed the then prominent hypogastric artery, the other at the point where it passed over the ureter. The latter was the one found in the adult in whom it had come to occupy a lower level. He found constantly a definite branch of the superior vesical artery passing inwards, reaching the ductus just distal to (*i.e.*, on scrotal side of) the kink, and there dividing in a V-shaped manner, one branch going upwards along the ductus, the other passing to the interval between the horizontal portion of the ductus and the seminal vesical giving twigs to both. No branch passed to the region of the kink.

He considered that the cause of the kink was the impinging of the ductus against the ureter when its course was changed by the descent of the testicle, and that the curvature was provided for and maintained by the peculiar distribution of the artery referred to.

THE DAILY FOOD RATION OF GREAT BRITAIN.

Professor THOMPSON made a communication on the above. From a survey of the total food supply of Great Britain for the year of the first census of

production (1908) the only year for which it was so far possible to make anything like an accurate computation, the daily food supply per man of the population, as calculated from the returns, came out to be as follows:

Flour and meal	14½	ozs.
Flesh meat	8	"
Fish	2	"
Potatoes	15½	"
Other vegetables	4¾	"
Milk	¾	pint.
Butter	1	oz.
Cheese	½	"
Condensed milk	⅓	"
Less than half an egg		
Fresh fruit	3 4/5	"
Dried fruits and nuts	½	"
Cocoa and chocolate	1/10	"
Salad oil	1/100	"

This ration provided the following:—

Protein.	Carbohydrate.	Fat.	Energy value.
101.49 grms.	587.12 grms.	136.36	4,127 calories.

The returns did not, however, include all the home supply of cheese, eggs, poultry, or rabbit meat. The estimate of green vegetables consumed as human food, particularly of cabbage, was probably also too low. Making additions to cover these omissions, would bring the ration up to:—

Protein.	Carbohydrate.	Fat.	Energy value.
104.26 grms.	587.84 grms.	138.83 grms.	4,167 calories.

As a fair estimate it would be safe to say that the British food ration per man per day did not exceed

Protein.	Carbohydrate.	Fat.	Energy value.
105 grms.	590 grms.	140 grms.	4,190 calories.

Making deductions for loss in distribution, the value of the ration, as purchased, would approximately be:—

Protein.	Carbohydrate.	Fat.	Energy value.
97 grms.	345 grms.	132 grms.	3,875 calories.

This did not provide more than enough for moderately hard muscular work. Dr. Langworthy placed the energy value of the ration, as purchased, for light work at 3,800 calories. The ration was remarkable in the relatively large amount of fat it contained, but in this respect it corresponded closely with the estimate of the German food supply before the war, as published by the Eltzbacher Committee. Two conclusions were drawn, namely—(1) that the tendency in urban and industrial populations was to increase the consumption of fat at the expense of the protein; and (2) that the ration could not well be reduced without endangering the efficiency of the working man. Economy could, however, be introduced by substituting protein from vegetable sources for a further part of the more costly meat supply.

OBITUARY.

DEPUTY SURGEON-GENERAL E. F. O'LEARY, M.D., M.R.C.S.

DEPUTY SURGEON-GENERAL EUGENE FRANCIS O'LEARY died at Audley, Sidmouth, on February 20th, in his eighty-first year. Qualifying M.R.C.S.Eng. in 1856, he entered the army in the same year, and was placed on the Retired List, December, 1883. He served many years in India and China, and in the Egyptian campaign of 1882, for which he received the medal and the Khedive's Star. In 1870 he graduated M.D., R.U.I.

SURGEON-GENERAL C. E. McVITTIE, L.R.C.P.Ed., F.R.C.S.I.

THE death has taken place at Exmouth of Surgeon-General Charles Edwin McVittie, an honorary physician to the King, late of the Indian Medical Service. He qualified as licentiate of the Royal College of Surgeons, Ireland, in 1865, and of the Royal College of

Physicians, Edinburgh, in 1866, being elected a fellow of the Royal College of Surgeons, Ireland, in 1874. He joined the Indian Medical Service in Madras, and served in the Afghan War in 1880, for which he had the medal, and with the Burmese Expedition in 1886-7, when he was mentioned in despatches and received the medal with two clasps. He reached the rank of surgeon-general in 1895, and retired in 1900. Surgeon-General McVittie was an honorary physician to Queen Victoria from 1898 till 1901, to King Edward during his reign, and to the present King since his Majesty's accession to the Throne. He was given a distinguished service reward in 1894.

DR. GEORGE VALENTINE, M.B., C.M., GIRVAN.

THE Kingdom of Carrick is poorer to-day by the death of Dr. Valentine. He had been in somewhat failing health for the past two years, but was able to do the more important part of his work till a fortnight ago, when he was suddenly seized with apoplexy, which proved fatal in a few hours. He was a native of Stonehaven, where he was born 68 years ago. Graduating at Glasgow University in 1873, he began practicing in South Ayrshire over forty years ago, as Medical Officer of the Parish of Girvan. He was a Medical "Kim," the friend of all the world. Genial and likeable in his disposition, he was most shrewd and wise, and though the latest mechanical devices of our art were more or less unfamiliar to him, his opinion on a case, medical or surgical, was well worth hearing. He was a fine type of the old country doctor at his best. He is survived by a widow, two daughters and six sons, two of whom are in the medical profession.

DR. A. T. CAMPBELL, M.B., C.M. Glasg.

THE death occurred, on February 22nd, at Glasgow, of Dr. Archibald Thomson Campbell. Dr. Campbell, who had been in ill health for some months, had been on military service since the beginning of the war. He held a commission in the Home Hospitals Reserve, R.A.M.C., and on the outbreak of war he was called up. He was posted to Maryhill Barracks, and with the rank of captain served there till the state of his health compelled him to go off duty. Dr. Campbell qualified M.B., C.M. at Glasgow in 1886, and began practice in that city in 1888. He took an active part in the work of the various professional organisations. He held at different periods the offices of President of the Glasgow and West of Scotland Branch of the British Medical Association, President of the North-Western branch of the same body, and President of the Northern Medical Association. At the time of his death he was Chairman of the local Medical Panel Committee under the National Insurance Act, in the activities of which he was very keenly interested. He was also one of the representatives from Glasgow to the British Medical Association in London. Dr. Campbell is survived by his wife and a family of three.

DR. C. L. H. PEMBERTON, M.D., M.R.C.S., L.S.A., BANBURY.

THE death took place, on February 15th, of Dr. C. L. H. Pemberton, the senior medical practitioner of Banbury. Beginning practice between 50 and 60 years ago, he gained a wide reputation in his skilled treatment of pneumonary disease. He was trained at Birmingham and Paris, qualifying M.R.C.S. in 1857 and L.S.A. in 1858. In 1896 he took the M.D. Brux. degree. Dr. Pemberton practised alone for many years, and during that time several medical institutions were aided largely by his knowledge of their need and requirement. The Horton Infirmary was in 1870 his interest, and after 26 years of voluntary service, during which he saw the institution extend its good work, he became the Honorary Consulting Medical Officer, an office retained until his death. The Banbury Nursing Association was equally indebted to his work, and he occupied the presidency until comparatively recently. Eleven years ago he retired from active professional duty. The deceased was 80 years of age.

DR. R. MILNTHORPE, M.R.C.S., L.R.C.P.,
LEEDS.

DR. RICHARD MILNTHORP, of Leeds, died from pneumonia on Feb. 18th, at the early age of 41. Educated at Leeds, he qualified M.R.C.S., L.R.C.P. in 1900. During the Boer war he acted as Surgeon with the temporary rank of captain, and for a few years after his return he was Surgeon to the soldiers at Chatham. He spent a short time in Batley and Dewsbury before settling down in Leeds. At the outbreak of the present war he offered his services to the military authorities, but his state of health was such that he could not be accepted. He was married, and is survived by his widow and one boy.

DR. A. CARMICHAEL, M.A., M.D.

DR. ARCHIBALD CARMICHAEL, of Barrow, has died suddenly at Perth. He had been in practice in Barrow since 1871, and retired just over a year ago. He graduated M.B., C.M. at Aberdeen in 1871, and M.D. in 1873. He was Medical Referee under the Factory Acts and Workmen's Compensation Act. He was 69 years of age.

SPECIAL REPORTS.

FRENCH AND BELGIAN HONOURS FOR BRITISH DOCTORS.

FRENCH DECORATIONS.

LEGION OF HONOUR.

The President of the French Republic has bestowed the decoration of the Legion of Honour, with the approval of His Majesty the King, on the following officers, in recognition of their distinguished service during the campaign:—

CROIX DE COMMANDEUR.

Surg.-Gen. W. G. Macpherson, C.B., C.M.G., M.B., K.H.P.; Col. Sir W. B. Leishman, C.B. F.R.S., A.M.S.

CROIX D'OFFICIER.

Col. C. H. Burtchaell, C.M.G., A.M.S.

CROIX DE CHEVALIER.

Maj. W. R. Battye, D.S.O., M.B., F.R.C.S., I.M.S.; Maj. R. B. Black, M.B., Res. of Off., R.A.M.C.; Maj. J. S. Pascoe, R.A.M.C.; Maj. E. Ryan, D.S.O. R.A.M.C.; Maj. J. W. West, M.B., R.A.M.C.; Capt. F. Casement, M.B., R.A.M.C.; Capt. D. M. McWhae, Australian A.M.C.; Capt. (temp. Maj.) J. Morley, M.B., F.R.C.S., R.A.M.C. (T.F.); Lt. (temp. Capt.) J. W. Craven, R.A.M.C. (T.F.).

BELGIAN DECORATIONS.

THE KING has been graciously pleased to grant unrestricted permission to the undermentioned Officers to wear the decorations specified, which have been conferred by his Majesty the King of the Belgians for distinguished service during the campaign:—

Surg.-Gen. Sir Arthur Thomas Sloggett, K.C.B., C.M.G., K.H.S.—Commandeur de l'Ordre de Leopold; Surg.-Gen. Robert Porter, M.B.—Commandeur de l'Ordre de la Couronne; Col. Samuel Guise Moores, C.B., Army Medical Service.—Officier de l'Ordre de Leopold; Lt.-Col. S. L. Cummins, C.M.G., M.D., R.A.M.C.—Officier de l'Ordre de la Couronne; Lt.-Col. A. Chopping, C.M.G., R.A.M.C.—Officier de l'Ordre de la Couronne.

HONOUR FOR NAVAL MEDICAL OFFICER.

THE KING has further been graciously pleased to approve of the award of the Distinguished Service Cross to:—

Surg. Alfred Robinson MacMullin, R.N., for his services on January 23rd, 1916, at Serengeti, in East Africa, when he showed remarkable bravery in searching for and rescuing a severely wounded officer under heavy machine-gun and rifle fire close to concealed enemy entrenchments.

REVIEWS OF BOOKS.

VENEREAL DISEASES (a).

ONE is led to expect much that is original and of interest from a book that bears so promising a title and is written by so well-known a writer. Those who read this work will find that this expectation is more than justified. Mr. McDonagh is not afraid to discard generally accepted theories and to replace them by others founded upon his own personal observation and research work. There is no question that he is a keen observer and an untiring worker, but whether he is always justified in his deductions is a matter which must necessarily for a time remain in suspense. The opening chapter gives a brief but interesting history of the search for the organism of syphilis, and gives the author's reasons for thinking that the *Spirochæta pallida* of Schaudinn and Hoffmann is only one stage in its life-cycle. Mr. McDonagh claims to have worked out the whole life-cycle of the organism, and has named it the *Leucocytozoon syphilidis*. He shows many excellent plates and photographs of its various stages, and explains how its chemistry and different phases throw light upon previously unexplained phenomena of syphilis. The Wassermann reaction and the other tests for syphilis are thoroughly discussed, and the chapter on the *rationale* and significance of the Wassermann reaction is well worthy of the most careful study. The author very fully describes the clinical and pathological aspects of both acquired and congenital syphilis in the various parts of the body. He divides the disease into four stages, the initial, the generalisation, the latent, and the recurrent, and advises the adoption of this instead of the existing classification. He also tells us that the type of chancre often affords a guide to prognosis and treatment.

The other venereal diseases and non-venereal conditions which may come under the notice of a venereal specialist are very adequately considered. Those chapters devoted to gonorrhœal infection are especially interesting. The pages on general neurasthenia form very valuable and instructive reading. In the two final chapters in this part of his work the author gives his views on the eugenic aspect of venereal disease in relation to marriage and public health.

In the second part of this book Mr. McDonagh brings forward evidence to show how some of the protective phenomena of the body, when carried to excess, may lead to the occurrence of malignant disease. In this work the author supports his various deductions with the histories of nearly a hundred of his cases and by many excellent coloured plates and photographs.

The book, which is particularly well printed and illustrated, bears the stamp of Mr. McDonagh's personality, and is well worthy of careful study, not only by those who will eagerly agree with its many new ideas, but also by the more conservative members of the medical profession. We cordially congratulate Mr. McDonagh upon a work which represents a vast amount of exacting labour and original thought; neither specialist nor general practitioner can afford to remain ignorant of the advance which it represents.

THE SECRET OF HUMAN POWER. (b)

IT was said of the late James Hutchison Stirling, when he wrote a book on "The Secret of Hegel," that if he knew the secret, he kept it to himself. We fear that Mr. Haydn Brown has left himself open to a similar criticism. We have read his book with considerable care, and we regret to say that we have been unable to form any real conception of what he considers to be his message. Our difficulty is made greater by his lack of arrangement and by his extraordinary style. The book is made up of a number of chapters or discussions on various subjects, between

(a) "The Biology and Treatment of Venereal Diseases and the Biology of Inflammation and its Relationship to Malignant Disease." By J. E. R. McDonagh, F.R.C.S. Eng. Pp. 625. Plates 54. London: Harrison and Sons. Price £1 5s. net.

(b) "The Secret of Human Power." By Haydn Brown. Cr. 8vo. Pp. 328. London: Geo. Allen and Unwin. 1915. Price 5s. net.

which we are unable to discover any logical relation. The split infinitive is the smallest of his crimes of style, the ordinary rules of grammar being treated without any respect. Opening the book at random to choose a typical example of Mr. Brown's writing, the following sentence first caught the eye:—"It is a pretty sight, and an instructive exposition of reflex action having the purpose of saving a fall by entangling its fingers and clutching its hands in something should the mother in parturition drop it a distance away from the ground." We have been unable to discover the meaning of the diagrams which are intended to illustrate psychological processes. There is, of course, in the book a good deal of sound if somewhat commonplace advice, and Mr. Brown backs his opinions by extracts from many teachers varying in authority from Marcus Aurelius to Mr. T. P. O'Connor.

DISEASES OF CHILDREN. (a)

DR. STILL'S work, "Common Disorders and Diseases of Childhood," having reached its third edition in five years, may be said to have passed from the reviewer's hands, and to have been definitely accepted by the medical profession. We have merely to say to those who do not know the book that it is well worth their study, and to tell the many readers of former editions that the new edition is, if possible, better than the old. New matter has been added, and old opinions have been sifted in the light of further experience, so that, besides being more complete, the book is more trustworthy than ever. We predict for Dr. Still's work a long and useful career.

LITERARY NOTES.

MESSRS. H. K. LEWIS AND CO., LTD., announce for early publication the following books:—

"Localisation by Röntgen Rays and Stereoscopy," by Sir James Mackenzie Davidson; it is fully illustrated with stereoscopic and other pictures. "The Pathology of Tumours," by Dr. E. H. Kettle, with 126 illustrations from original drawings and other material. A new volume of essays by Dr. T. B. Scott, entitled "Modern Medicine and some Modern Remedies," to which Sir Lauder Brunton has contributed a preface. "Notes on Galvanism and Faradism," by Dr. Magill, intended for masseuses, and fully illustrated. "The Adolescent Period: Its Features and Management," by Dr. Louis Starr. A new edition (the fourth) of "Mentally Deficient Children," by Dr. G. E. Shuttleworth and Dr. W. A. Potts; revised and in part re-written, with increased illustrations. A new (seventh) edition of Gould's well-known "Pocket Medical Dictionary," containing an additional 1,000 words (35,000). A revised and greatly enlarged edition of Dr. Herbert Tilley's "Diseases of the Nose and Throat" is in the press. The seventh edition of Binnie's "Operative Surgery" will be ready early in March; it has again been thoroughly revised. A small but important new book by Dr. Russ on "A New Treatment for Gonorrhœa" is also nearly ready.

* * *

More than two-thirds of the January issue of the *British Journal of Surgery* (John Wright and Sons, Bristol. Price 2s. per annum.) consists of contributions to the surgical literature of the present war. That these contributions are valuable and authoritative goes without saying, since they come from the pens of eminent civilian surgeons, whose services have been specially retained by the War Office as consultant surgeons with His Majesty's Forces. Surgeon-General Sir Geo. Makins contributes a lengthy and informing report on the various vascular lesions which have come under his notice during the past year of war: he specially comments

upon the devastating nature of these injuries, when compared with the relatively limited type of lesion encountered during the South African campaign. His observations on the terribly destructive effect of modern projectiles are amply confirmed in Surgeon-General Sir Anthony Bowlby's Bradshaw Lecture on Wounds in War, which is reproduced in this issue. To a wide and varied experience of civil surgery both these surgeons can claim the additional advantage of military experience gained during the South African campaign, and each has found the condition of wounds in these two campaigns to be widely different in nature. The radical difference of terrain suffices to explain the almost universal sepsis which came as such a surprise to the younger generation of surgeons on the outbreak of this war, and the higher velocity and greater instability of the modern rifle bullet would appear to produce much more smashing and rending of tissues than did the bullet of fourteen years ago.

In general, wounds received in South Africa were much less severe, and liable to far less serious complications than those with which most of us to-day are only too familiar. The special characteristic of the modern gunshot wound is the rending asunder of the tissues penetrated, largely due to the wave of compressed air which the bullet drives in front of it, and which expands within the tissues. Hence the injury inflicted is not confined to the track of the penetrating missile, but is diffused in every direction, radiating through all the surrounding tissues. Such extraordinarily far-reaching effects are well illustrated in certain cases cited by Sir A. Bowlby where intestines have been actually found torn open by bullets without the peritoneal cavity having been opened. The grave complication of a most persistent type of sepsis is incurred in every one of these wounds, and their treatment by modern aseptic methods would appear to have been uniformly disappointing. The views of Sir A. Bowlby and of Sir Watson Cheyne show that a reversion to vigorous antiseptic methods, combined with a system of free drainage, is absolutely essential for their successful treatment. Dr. Grüner's researches on the behaviour of the leucocytes in malignant disease are worthy of attentive study, and his paper is beautifully illustrated. Major Warner contributes a not untimely warning on some of the dangers of drainage tubes.

LABORATORY NOTES.

COMPOUND MENTHOL SNUFF. (BURROUGHS WELLCOME AND CO., SNOW HILL BUILDINGS, E.C.)

Compound Menthol Snuff (B. W. and Co.) has long been employed in the treatment of common colds, hay fever, and other nasal conditions. It has hitherto been put up in enamelled metal boxes, shaped like a snuff-box, and provided with an inner cardboard container. For use in temperate climates this packing has been found perfectly satisfactory and convenient, and will be retained. In tropical countries, however, certain risks of deterioration through the influences of heat and humidity have been recognised, while the metal box is apt to become unsightly through damp attacking the metal should the enamel be chipped or scratched in use. For tropical use, therefore, the product is now issued in a watch-shaped bottle, securely corked, waxed, and fitted with a screw cap cover. This is in size and shape convenient for the waistcoat pocket, and securely guards the contents against risk of deterioration.

"FORMITROL" FORMALIN PASTILLES. (A. WANDER, LTD., 45 COWCROSS STREET, E.C.)

We have received a specimen of the above product. Each pastille is enclosed in a metallic sheath, which prevents evaporation of the formaldehyde. A neat tin container, suitable for carrying in the pocket is supplied, containing 30 pastilles. Experiment has shown that after slow solution in the mouth of one pastille the saliva contains 0.2 per cent. formaldehyde. An interesting booklet is issued, giving the results of

(a) "Common Disorders and Diseases of Childhood." By George Frederic Still, M.D., F.R.C.P.Lond. Third edition. 8vo., pp. xvi. and 845. Illustrated. London: Henry Frowde, Hodder and Stoughton, 1915.

experiments with gelatin culture media sown with virulent cultures of *B. coli*, *B. diphtheriæ*, and other micro-organisms. These support the claim that the product affords a reliable means of treatment in septic conditions of the mouth and throat.

MEDICAL NEWS IN BRIEF.

Royal Society of Medicine, London.

DR. M. WEINBERG, of the Pasteur Institute, Paris, will deliver a lecture on "Bacteriological and Experimental Researches on Gas Gangrene," with epidiascope demonstration, cultures, etc., in the Robert Barnes Hall, on Friday, March 10th, at 5 p.m.

Public Retrenchment.

THE final report of the Committee on Retrenchment in Public Expenditure was issued on February 26th. Amongst the recommendations of the Committee are the following:—

The reports of certifying surgeons on accidents in factories should be dispensed with.

A reduced contribution should be prescribed towards the cost of institutional treatment for mentally defective persons except in urgent cases, and a limitation should be fixed on the cost of maintenance in all cases.

The fees paid to medical practitioners for notification of infectious diseases should be reduced.

Children under five should only be admitted to schools in special cases, and grants should not be paid in respect of such children.

The Board of Education should institute an inquiry into the possibility of introducing a normal minimum age of six.

The responsibility for medical work, except in public elementary schools, should be transferred from the Board of Education to the Local Government Board, and the first opportunity should be taken of amalgamating the medical branches of the two Departments.

Arrangements should be made to reduce the number of Health Insurance Commissioners.

A special inquiry should be held into the cost of the Insurance Commissioners' staffs, particularly in the case of the Welsh and Irish Commissions.

Extra-statutory grants to approved societies, etc., outside the principle of insurance, should be closely restricted.

A special inquiry should be undertaken with a view to the simplification of the Insurance Act.

National Insurance in Scotland.

SIR JAMES LEISHMAN, Chairman of the Scottish Insurance Commissioners, attended the annual meeting of the Ancient Order of Free Gardeners' (Scotland) Insured Association, which was held in Edinburgh on February 19th. Reviewing the position of national insurance in Scotland, he remarked that there were more than 1,500,000 insured persons in Scotland. Voluntary insured persons were only 3,000, and judging by members, voluntary insurance in Scotland was a failure. He thought that people should be careful when they made statements about impending bankruptcy, insolvency and that sort of thing. If he were to take Scotland as a whole, up to the present time the insurance fund would be solvent, and would be able to meet its claims.

Welsh Medical School.

At a meeting of the Court of Governors of the University College of South Wales and Monmouthshire, held at Cardiff on February 17th, Principal E. H. Griffiths said it had been a matter of deep regret that the Treasury had thought fit to incorporate this with the question of re-organisation of the University. Sir William James Thomas had not offered £90,000 to re-organise the University. It was the poorest encouragement to similar generosity in the future, and he trusted that the Governors would press in every way on the Treasury the advisability of allowing them to proceed

with the school buildings. They had undertaken that no one who could be of use in the forces should be employed on the work, and when no State money was to be employed he did hope the Government would see its way to yield to the unanimous request made by the other three constituent colleges, by the King Edward VII. Hospital, and by the University, and allow them to realise the great gift of Sir Wm. James Thomas without further delay.

King's College Hospital.

THE REV. A. C. HEADLAM, presiding on February 24th, at the annual meeting of King's College Hospital, said that the normal number of beds was 358. Special arrangements were made by the Committee to enable them to provide upwards of 600 beds for sick and wounded soldiers. The number of beds in daily use was 653, of which 514 were occupied by military patients.

Orthopædic Hospital in Ireland.

THE annual meeting of the governors and supporters of the hospital was held last week, Mr. Justice Ross being in the chair.

The report, which was submitted by Miss Agnes French, secretary, stated that during the past year 162 children were under treatment. Of these 52 were discharged, cured; 30 were discharged, improved; one was removed to another hospital; three were discharged as not ready for treatment; only one died; and 75 remained under treatment on the 31st December.

With regard to the income of the hospital, the governors regretted that the subscriptions and donations were £177 8s. 3d. less than last year, and urged upon friends of the charity the necessity of extending the revenue.

Bogus Practitioner.

F. FISHER, of London, was sent to prison at Glasgow on February 23rd for one month, having pleaded guilty to obtaining employment on a Donaldson liner at Newport News by falsely representing himself to be a registered medical practitioner, having previously obtained diplomas and certificates of a man at one time a distinguished graduate of Cambridge University. The graduate's effects had been sold in a London auction room, and Fisher purchased a case which contained some of his documents. Fisher also admitted that he obtained £12 10s. on the liner's arrival in Glasgow, the sum being payable to the registered medical practitioner for the journey as the ship's surgeon. Fortunately there was no illness on board the liner during the voyage.

Summons against a Leeds Medical Specialist.

At the Leeds Police Court, on February 23rd, Thos. Wright, of Lewis Street, trading as Mr. and Mrs. W. Wood, medical specialists, was summoned to show cause why certain printed matter should not be destroyed.

The Stipendiary Magistrate (Mr. Horace Marshall) held that, however undesirable, the business of the defendant was not illegal, and said that while in the public interest an engraving on the pamphlet in question was not the kind of picture to be exhibited, he could not see his way to convict the defendant in the sense of ordering that the printed matter should be destroyed. He accepted an offer made by the defendant to withdraw the picture, and there would be no order. All the goods and documents seized from the defendant would be returned to him.

Medical Staff of Liverpool Dispensaries.

SOME pointed criticisms on the drain which the Army is making on medical staffs of charitable institutions were uttered by Dr. E. W. Hope (Medical Officer of Health) at the annual meeting of the supporters of the Liverpool Dispensaries, held on February 23rd.

Dr. Hope, referring to the reduction of the medical staff of the dispensaries from nine to three, said that an indefinite extension of action of that kind must have the result of frustrating the very objects which the Government had in view. In enjoining economy, the

Treasury exempted two things. One was the efficient method of carrying on the war, and the other was the public health. What was to become of the ordinary population of the city if their general hospitals were turned into wards for soldiers, if the city was denuded of its doctors for military purposes, and if no provision was made for the very section of the population for whom our soldiers were fighting? The question was a difficult one to answer. It was profoundly obvious that there must be a limitation, and that was why a special debt of gratitude was due to those gentlemen forming the committee, officers and medical staff of the Liverpool Dispensaries, who, in their way, were endeavouring to "keep the home fires burning."

Indispensable Medical Officer.

ST. PANCRAS BOROUGH COUNCIL have decided that the services of Dr. Higgins, their medical officer, who is 31 years of age, are indispensable to the health of the borough and they have declined to allow him to join the Royal Army Medical Corps at the request of the military authorities.

Keighley Victoria Hospital.

THE annual meeting of the Keighley Victoria Hospital was held on 21st February. The report for 1915 stated that 747 civilian patients and 61 wounded soldiers had been admitted during the year, and that of the 747 civilian patients 582 were from the borough and 165 from the surrounding districts. During the year 652 operations had been performed. The average daily number of beds occupied was 34, the average period of residence 22 days, and the average cost per day per patient in provisions, 1s. 1d.

Medical Students and Attestation.

INTIMATION has reached the Universities from the Army Council that all medical students in their fourth and fifth years of study and those in their third year of study whose examination takes place during the winter session must either (1) Attest under the group system, or (2) Become liable to the Military Service Act.

London Panel Doctors and Insured.

In a review of their proceedings during 1915, the Medical Service Sub-Committee of the London Insurance Committee report that they dealt with 103 cases concerning questions which had arisen between insured persons and practitioners on the panel. Of these cases sixteen related to certificates, and with regard to the remainder the allegation in the majority was that the practitioner had been negligent in connection with treatment. It was found that 51, or 49.51 per cent. of such cases had been substantiated.

"Certain of the cases dealt with were of a very serious character, but it may be said that a large number of them were of a somewhat trivial nature, and when it is remembered that the insured population of London consists approximately of 1,500,000 persons, and also that there are about 1,500 medical practitioners on the panel, we consider that the number of cases is extremely low."

In two cases reported on by the sub-committee the Insurance Commissioners decided after enquiry that the names of the practitioners concerned should be removed from the medical list.

Oxford Ophthalmological Congress.

THE Hon. Secretary, Mr. Bernard Cridland, Salisbury House, Wolverhampton, states that the Oxford Ophthalmological Congress will assemble at Keble College, Oxford, on the evening of Wednesday, July 12th next, and the meeting will be held on Thursday, the 13th, and Friday, the 14th July.

Thursday, July 13th, will be devoted to a discussion on "The Relationship of Ophthalmology to General Medicine," to be opened in the morning by Sir William Osler, Bart., and in the afternoon by Sir Anderson Critchett, Bart., C.V.O. The following will also take part:—Mr. P. H. Adams (Oxford), Dr. F. E. Batten (London), Mr. F. Richardson Cross (Clifton, Bristol), Dr. A. G. Gibson (Oxford), Dr. T. S. Good

(Littlemore Asylum), Dr. C. O. Hawthorne (London), Dr. Thomas J. Horder (London), Mr. W. H. H. Jessop (London), Dr. George Mackay (Edinburgh), Mr. Leslie Paton (London), Mr. Sydney Stephenson (London), Dr. James Taylor (London), and others.

Friday, July 14th, will be given up to papers, demonstrations and cases.

It is hoped that members will make an effort to contribute to the success of the meeting with cases, specimens, new operations, or novelties of any kind. Such members are requested to notify the Secretary at the earliest opportunity.

More Room for the Wounded.

Sir Arthur Downes, medical inspector of the Local Government Board, is informing London boards of guardians that, in order to reduce the pressure in the infirmaries, and thereby to increase the accommodation for wounded soldiers, the Metropolitan Asylums Board has, at the request of the Local Government Board, arranged to establish further accommodation for sick children. For the purpose two additional institutions will be opened—namely, the Park School, Hanwell, and the Cleveland Street Infirmary, Westminster. The Metropolitan Asylums Board is now fully empowered to receive sick, convalescent, or debilitated children.

War Hospital Burned Down.

THE Grand Hotel at Wimereux, which has been occupied during the war by a British Hospital, was burned down on January 22nd, it is believed as the result of a short circuit. Owing to the coolness and devotion of doctors and nurses the sixty-six patients were safely removed, but the building was gutted.

Economy and Infant Life.

ST. PANCRAS BOROUGH COUNCIL having decided not to increase the health visiting staff, the Local Government Board has written pointing out the importance of conserving infant life even at a time when strict economy is required, and deeming the appointment of health visitors a matter of urgency which cannot be deferred.

Hull Tuberculosis Hospital.

THE Hull Corporation Health Committee, on January 24th, decided to sanction the removal of the tuberculosis patients at present in the Infectious Diseases Hospital to the new tuberculosis hospital with as little delay as possible. They also resolved to furnish and equip the new hospital so as to provide accommodation for 25 patients, and to engage the necessary administrative staff, consisting of a matron, a charge nurse, two staff nurses, two probationers, two ward maids, a cook, four maids, and a porter.

Leeds Hospital for Women and Children.

THE annual report of the above institution states that during the year 1,016 in-patients had been admitted, as compared with 1,179 in 1914. New out-patients had totalled 1,566, and the total number treated had been 5,001. The average number of beds occupied had been 64.5, and the average time spent in the hospital had been 16 days. The expenditure amounted to £4,776, as against £4,700 in 1914.

Bradford Royal Infirmary.

THE annual meeting of the Bradford Royal Infirmary was held on 22nd February. The report showed that in the in-patients department there had been 2,873 cases during the year, as compared with 3,059 in 1914, while in the out-patients department there were 4,059 as compared with 5,711. The total ordinary expenditure was £15,834 which was much in excess of the ordinary income, £14,427, and the Board appealed for still greater liberality in order that the work of the hospital might be carried on without any loss of efficiency.

The Woodlands Convalescent Home at Rawdon has during the year been principally used for disabled soldiers. Much needed alterations and improvements

at the home would require £1,500, and the Committee made an urgent appeal for donations.

Royal College of Surgeons.

A MEETING of the Council of the Royal College of Surgeons was held on February 10th, with Sir Watson Cheyne, President, occupying the chair, when diplomas of membership were issued to 79 candidates who had passed the required examinations and conformed to the bye-laws. The list contained the names of nine lady students—Miss Isabel F. Buckle, Miss Mary N. Andrews, Miss Helen Ingleby, Miss Ivy Keess, Miss Gladys M. Miall-Smith, Miss May Olivera, Miss Edith M. Paul, Miss Edith A. Shaw, and Miss Elsie Stansfield.

The following gentlemen were also admitted members:—J. Andrew, G. F. V. Anson, K. L. Bates, T. A. P. Benbow, A. W. C. Bennett, K. H. Bhat, J. T. Bleasdel, E. S. Bowes, A. O. Courtis, D. Crellin, R. G. Dani, L. M. Davies, L. ap I. Davies, H. M. Drake, A. N. Drury, C. Y. Eccles, M. Elias, H. H. Elliot, C. A. L. Evans, D. J. Evans, M. D. Evans, W. J. Evans, C. Gould, H. E. Griffiths, A. B. Gunasekara, C. G. W. Hahr, A. E. Hamlin, W. L. A. Harrison, G. E. Heath, V. R. Hirsch, E. L. Hopkins, V. C. James, J. G. Jones, L. W. Jones, C. E. Kindersley, M. E. A. Latif, H. Lewis, K. T. Limbery, G. A. S. Madgwick, R. H. Maingot, L. A. Malik, F. W. Maunsell, R. D. Moyle, N. R. Nalliah, H. M. Oddy, P. R. O'Rourke Phillips, A. C. Pickett, D. S. Pracy, D. Rees, E. D. Richardson, M. K. Robertson, G. C. Robinson, J. T. Samuel, R. J. Scarr, C. P. Sells, G. B. Sellwood, A. Sunderland, G. T. Symons, H. J. H. Symons, A. H. Taymour, W. H. Thomas, J. A. Tippet, R. S. Topham, H. M. von Mengershausen, H. J. Wallace, H. A. Whyte-Vennables, H. G. E. Williams, A. Wilson, and G. C. N. Younger.

The Council passed a vote of condolence with the relatives of the late Lieut.-Colonel Stanley Boyd, R.A.M.C. (T.F.), who was a member of the Council.

Society of Apothecaries in London.

THE diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery and Midwifery:—W. F. R. Castle, L. Kahan, W. J. May, and G. S. Mitchell.

The Royal Society.

THE following 15 candidates have been selected by the Council of the Royal Society to be recommended for election into the Society:—

Barton, E. H., Prof.; Bousfield, W. R.; Brown, S. G.; Coker, E. G., Prof.; Henderson, G. G., Prof.; Littlewood, J. E.; McKenzie, A., Prof.; MacWilliam, J. A., Prof.; Maiden, J. H.; Pearson, H. H. W., Prof.; Pollock, J. A., Prof.; Rogers, L., Sir; Shearer, C., Dr.; Thompson, D'A. W., Prof.; Woods, H.

MEDICAL WAR ITEMS.

News has been received of the death in action of Lieut. Bernard Bradley Gough, Royal Army Medical Corps, of Compton Martin, Somerset. He was the son of the late Mr. H. Gough, barrister, Sandcroft, Redhill, and was born at Stockwell, Sept. 14, 1873. Entering Guy's Hospital as student in 1892, he was admitted M.R.C.S. and L.R.C.P. in 1897. He acquired a general practice at Compton Martin, Somerset, and in June, 1915, obtained a commission in the R.A.M.C. Later he was attached to the Royal Garrison Artillery. Mrs. Gough, his widow, who was matron at the Great Grimsby Hospital in 1900, is in command of the Military Hospital at Gourney Court, West Harptree, Somerset.

Major William Henry Odium, of the Indian Medical Service who has been wounded in Mesopotamia, was born in 1873, received his medical education in Dublin and Meath, and qualified L.R.C.P. and S.I. in 1898. He joined the Royal Army Medical Corps in 1900, and seven years later transferred to the Indian Medical Service, reaching the grade of major in September, 1914. During the South African War

he served as a civil surgeon, and at the end of the campaign got the Queen's medal with three clasps and the King's with two.

Lieut.-Colonel Hew Ramsay Duff, of the Canadian Army Medical Corps, who has died on active service in France, was born at Kingston, Ontario, in 1857. Educated at Kingston Grammar School and Queen's University, where he received his M.D. degree in 1884, he had been medical officer for the Quebec Tercentenary Celebrations in 1908 and president of the Army Medical Corps Board of Survey for Ottawa, Colonel Duff served during the South African War, and was awarded the Queen's medal with four clasps.

Lieutenant Francis Sidney Mitchell, M.B., Royal Army Medical Corps, attached Royal Sussex Regiment, 9th Battalion, whose death is announced, was the youngest son of Mr. George Mitchell, of Ardlui, co. Dublin, and was 26 years of age. He took his degree at Dublin University last year.

Captain William Mervyn Biden, M.B., Royal Army Medical Corps, attached to the 2nd Leinster Regiment, who has been wounded in the North of France, took his medical degree in 1910, at Edinburgh University, and before going to the front was in practice at Ketton, Stamford. For some time he was house physician and resident surgeon at the Salford Royal Hospital. Captain Biden got his present rank in the Royal Army Medical Corps a few days after the declaration of war.

Captain H. B. Cunningham, M.B., Royal Army Medical Corps (T.F.), attached Royal Field Artillery, 3rd Northumbrian (County of Durham) Brigade (T.F.), who has been wounded while serving in France, is a well-known Belfast surgeon and a son of the late Surgeon-General John Phillips Cunningham, M.D., of Carrickfergus. At the outbreak of war, Captain Cunningham was in practice in Belfast, and amongst the positions he has held are those of examiner in ophthalmology and otology to the Royal College of Surgeons, Ireland; ophthalmic surgeon to the Ulster Hospital for Women and Children, Belfast; and clinical assistant to the Belfast Ophthalmic Hospital. He formerly held commissions in the London Irish Volunteers, the 6th Battalion Royal Irish Rifles, and the 1st Battalion Royal Irish Fusiliers, from which he passed into the Reserve of Officers in 1903. Captain Cunningham served in the South African War, and holds the Queen's medal with three clasps and the King's medal with two clasps.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s. post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town, Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

DOCTOR'S BET.

DURING the hearing of a compensation case in the City of London Court, two doctors said a workman had a fractured leg, and two others declared that the leg had not been fractured.

Major Toogood, M.D., R.A.M.C., said he was quite positive about the fracture, and when pressed he offered to bet the doctors on the other side ten guineas that they were wrong. Judge Rentoul, K.C., smilingly said that betting could not be allowed in a court of justice.

TUBERCULIN (Lambeth).—The conclusions of the first report were:—(1) That phthisis is specially prevalent among workers in the boot and shoe industry, as compared with the general population; (2) the individual worker is predisposed to infection by the sedentary nature of his employment, and possibly by the attitude he adopts at his work; (3) the infection is probably (a) increased by the number of infective workers, and (b) favoured by want of light, the presence of infected dust, and inadequate ventilation in the workrooms.

INFANTILE MORTALITY AT DEWSBURY.

In his report for December, the Medical Officer of Health for Dewsbury (Dr. T. O. Halliwell) states that the birth-rate was 18.3 and the death-rate 16.6 per thousand of the population. There was an excessively high infantile mortality, the number of deaths of children under twelve months old being fifteen out of the total of seventy-seven deaths at all ages, and two other children died between the ages of one and two years.

THE KAISER'S POPULARITY.

An Irish recruit is said to have called for "three cheers for the Kaiser." Invited by his angry colonel to explain himself, he said, "Sure, sorr, if it hadn't been for the Kaiser there wouldn't have been any war."

"HOWLERS."

AMONGST the latest "howlers" perpetrated by American school children are mentioned the following:—

A vacuum is a large empty space where the Pope lives.

Pompeii was destroyed by an eruption of saliva from the Vatican.

Typhoid fever may be prevented by fascination.

INTERESTED (Southall).—The birth and infantile mortality rates in Middlesex in 1914—22.8 and 77.2 per 1,000 respectively—were the lowest since 1900. So was the death-rate—10.1 per 1,000.

THE DOGS OF WAR.

It is officially stated that the "Red Cross Dog League," which began activities early in the war with eight dogs, now has 2,500 in the field, each with its own trainer. It is claimed that the lives of at least 8,000 wounded men have been saved by these dogs.

Meetings of the Societies, Lectures, &c.

THURSDAY, MARCH 2ND.

ROYAL SOCIETY OF MEDICINE (SECTION OF BALNEOLOGY AND CLIMATOLOGY) (1 Wimpole Street, W.).—5.30 p.m.: Paper:—Dr. Clippingdale: The Thames Valley—Certain of its Natural and Medical Attributes. Report of the Committee of the Council. (At 7.15 p.m. the members will dine together at Pagani's Restaurant, Great Portland Street, W., and members may bring guests. Members who wish to dine are requested to send their names to Dr. J. Campbell McClure, 59 Harley Street, W.)

FRIDAY, MARCH 3RD.

ROYAL SOCIETY OF MEDICINE (SECTION OF LARYNGOLOGY) (1 Wimpole Street, W.).—4 p.m.: Specimens will be shown by Sir William Milligan, Mr. Thomas Guthrie, and Dr. Watson-Williams. Cases will also be shown.

ROYAL SOCIETY OF MEDICINE (SECTION OF ANESTHETICS) (1 Wimpole Street, W.).—8.30 p.m.: Paper:—Captain G. Marshall, R.A.M.C.: The Choice of Anesthetics at a Casualty Clearing Station. Demonstrations:—Dr. Harold Low: An Apparatus for the Intra-tracheal Insufflation of Ether. Dr. F. E. Shipway: An Apparatus for the Administration of Warm Anesthetic Vapours.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith Road, W.).—8 p.m.: Cases 8.30 p.m.: Paper:—Mr. J. G. Pardee: Prostatitis, Acute and Chronic.

MONDAY, MARCH 6TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—9 p.m.: Third Lettsomian Lecture will be delivered on "The Effects of High Explosives on the Central Nervous System," by Major Fred. W. Mott, M.D.Lond., Hon. L.L.D.Edin., Z.R.S.

Vacancies.

Stockport Union: Stepping Hill Hospital.—Resident Assistant Medical Officer. Salary £300 per annum, together with furnished apartments, rations, etc. Applications to C. F. Johnson, Clerk to the Guardians, Union Offices, Shaw Heath, Stockport.

Salford Poor-law Union Infirmary.—Resident Assistant Medical Officer. Salary £300 per annum, with furnished apartments, attendance, and rations in the Infirmary. Applications to E. H. Inchley, Poor-law Offices, Eccles New Road, Salford.

Leeds Public Dispensary.—Lady Resident Medical Officer. Salary £130 per annum, with board, residence, and laundry. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

The Royal Surrey County Hospital, Guildford.—House Surgeon. Salary £150 per annum, with board, residence, and laundry. Applications to the Secretary.

Ingham Infirmary and South Shields and Westoe Dispensary.—House Surgeon. Salary £150 per annum, with residence, board, and washing. Applications to John Potter, Secretary.

Cambridgeshire Asylum, Fulbourn, near Cambridge.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

London Fever Hospital, Liverpool Road, N.—Assistant Resident Medical Officer. Salary £200 per annum, with residence and board. Applications to the Secretary.

Royal Victoria and West Hants Hospital, Bournemouth.—House Surgeon. Salary £150 per annum, with board, lodging, and washing. Applications to Gordon M. Saul, Secretary.

The Royal Infirmary, Sunderland.—Lady House Surgeon.—Salary £150 per annum, with board, residence and laundry. Applications to Thomas Robinson, Secretary.

Appointments.

BAKER, Madeleine S., M.D., B.Ch., Assistant School Medical Officer, Acting School Medical Officer to the Bristol Education Committee for the period of the war.

BRADLEY, F., M.B., B.Ch., N.U.L., Certifying Factory Surgeon for the Fintona District, co. Tyrone.

CRONE, J. S., L.R.C.P.Irel., L.S.A., Deputy Coroner for West Middlesex.

LEONARD, T. J., M.D.Lond., Certifying Surgeon under the Factory and Workshop Acts for the Glaslough District of the County of Monaghan.

LOVE, R. J., L.R.C.P. and S.Edin., Certifying Factory Surgeon for the Staplehurst District, co. Kent.

Births.

CHILD.—On February 19th, at Mayfield, Winchester, the wife of Dr. Francis Child, of a daughter.

LEYTON.—On February 20th, at 92, Portland Place, W., to Dr. and Mrs. Leyton—a son.

PARRY PRICE.—On February 21st, at Castle Hill, Reading, the wife (*nie* Elsie Bevan) of Hoel Parry Price, Surgeon, Royal Navy, of a son.

TINNE.—On February 22nd, at Oak Cottage, Grassendale, Liverpool, the wife of Dr. P. F. Tinne, of a daughter.

WHITE.—On February 22nd, at West Knoll, Bournemouth, the wife of Edward How White, M.B.Oxon., of a son.

Marriages.

HARNETT—PERIGAL.—On February 23rd, at Holy Trinity Church, New Barnet, W. George Harnett, M.D., R.A.M.C., son of the late Dr. Harnett, of Barnet, and Mrs. Harnett, to Edith de St. Ien, youngest daughter of Dr. and Mrs. Perigal, of New Barnet.

INGRAM—MAGTAGGART.—On February 19th, at St. Mary Abbots, Kensington, Percy Cecil Parker Ingram, M.B.Lond., Captain, R.A.M.C. (T.F.), eldest son of Colonel S. D. Ingram, V.D., to Dorothy Fanny Mactaggart, daughter of Edmonds Massey, of the Stock Exchange, and widow of F. D. Mactaggart, of Singapore.

MEYER—STIRLING.—On February 23rd, at St. George's, Hanover Square, W., W. C. B. Meyer, F.R.C.S.E., Captain, R.A.M.C. (S.R.), son of the late Rev. C. Meyer, S.A., to Alice Elizabeth, daughter of Mr. and Mrs. Alexander Stirling, "Morven," Perth.

VICKERS—WILLIAMS.—On February 21st, at St. Nicholas (the Parish) Church, Chiswick, Lieutenant Harold Vickers, M.R.C.S., L.R.C.P., R.A.M.C. (T.), eldest son of Mr. and Mrs. Albert Vickers, of Cape Town and Chiswick, to Ida Rylands Williams, adopted daughter of D. Owen Jones, of Bangor, Carnarvonshire, North Wales.

Deaths.

GOUGH.—On February 16th, in France, Bernard Bradley Gough, Temporary Lieutenant, R.A.M.C., of Compton Martin, Somerset.

HOUGHTON.—On February 17th, in London, suddenly, of heart failure, Arthur Noel Houghton, M.B., Ch.B., M.R.C.S., L.R.C.P., only son of Charles Vince Houghton, of Auckland, New Zealand.

KEOWN.—On February 26th, at 44, Windsor Road, Ealing, W., David Boyd Keown, M.R.C.S., L.R.C.P.Lond., youngest son of the late Lieut.-Col. Henry Keown, 15th Hussars, aged 50.

MITCHELL.—Killed in action in France, on February 15th, Francis Sidney Mitchell, M.B., Lieutenant, R.A.M.C., youngest son of George Mitchell, of Ardlui, Co. Dublin, aged 26.

PATTISON.—On February 22nd, at a nursing home, Peterswald Pattison, Lieutenant, R.A.M.C., younger son of the late Gilchrist Gray Pattison, Edinburgh.

RUTHERFORD JONES.—On February 26th, 1916, at 139 Oakwood Court, Henry John Rutherford Jones, Captain, R.A.M.C., on service, aged 49 years.

STEPHENSON-JELLIE.—On February 21st, at 1, Clifton Road, Weston-super-Mare, Dr. J. Stephenson-Jellie, late of Rocklyn-Llantrissant, Clifton, and of King's Moss, Co. Antrim, aged 74.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, MARCH 8, 1916.

No. 10.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravants les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

THE Central Medical War Committee recently issued a circular setting forth its plan for "enrolling all medical men of military age for service, if and when required, in the R.A.M.C. or the medical service of the Royal Navy." The penultimate paragraph of this circular reads as follows: "It is to be specially noted that one great privilege is given to the medical profession that does not apply to any other section of the community—namely, that a medical man can enter the R.A.M.C. on a contract for one year's service, whereas everyone else must join the Services for the duration of the war. *It cannot be assumed, however, that the same privilege will be accorded to those practitioners who fail to enrol with our Committee.*"

THE passage which I have italicised, astounding as it is, will scarcely surprise the profession which the Central Medical War Committee claims to represent. A more gratuitous, insolent and vulgar threat could scarcely be imagined. Its edified readers will naturally be set a-wondering as to which of the members of the Central War Committee were responsible for the perpetration of such an outrage upon good taste and right feeling. It is signed by the secretaries—Mr. N. Bishop Harman, a prominent member of the B.M.A., and Dr. Alfred Cox, its medical secretary, neither of whom appears to be more than two or three years beyond the military age for the profession. The words of Moses spoken to the children of Gad and the children of Reuben might suitably be addressed to these young gentlemen: "Shall your brethren go to war, and shall ye sit there?"

BUT while we have learnt not to expect from the B.M.A. any evidences either of good taste or delicate feeling, we certainly expect these qualities in some of those who have been moved to unite themselves with the Association for the purposes of the Central War Committee. The full list of this committee is published at the head of the circular in question. It reads as follows:—

Mr. T. Jenner Verrall, LL.D., Bath, Chairman.
Sir William Osler, Bart., F.R.S., Oxford.
Sir T. Clifford Allbutt, K.C.B., F.R.S., Cambridge.
Dr. Frederick Taylor, President Royal College of Physicians, London.
Sir Rickman Godlee, Bart., Ex-President Royal College of Surgeons of England.
Prof. Harvey Littlejohn, Dean of the Faculty of Medicine, University of Edinburgh.
Dr. A. E. Shipley, F.R.S., Master of Christ's College, Cambridge.
Dr. T. W. Shore, Dean of the Medical School of St. Bartholomew's Hospital.
Sir Alex. Ogston, K.C.V.O., LL.D., Aberdeen (President, B.M.A.).
Mr. E. B. Turner, F.R.C.S., London (Chairman of Representative Meetings, B.M.A.).
Dr. J. A. Macdonald, LL.D., Taunton (Chairman of Council, B.M.A.).
Dr. Edwin Rayner, Stockport (Treasurer, B.M.A.).
Lieut.-Col. Sir James Barr, LL.D., Liverpool.
Lieut.-Col. R. A. Bolam, Newcastle-on-Tyne.
Dr. C. Buttar, London.
Major Russell Coombe, Exeter.
Major J. Galloway, London.
Major W. J. Greer, Newport, Mon.
Major Albert Lucas, Birmingham.
Dr. Thomas Hennessy, Joint Hon. Sec. Irish Medical War Committee.
Dr. B. A. Richmond, Secretary, London Panel Committee.

Now it is quite evident that, the chairman apart, the first six names on this list are what on commercial prospectuses are called "front page names." They are there to inspire confidence in the unthinking, and represent ornament rather than strength. Some of these gentlemen may be members of the Association, but if they are, their names appear, not in virtue of that membership, but because of the distinction which they and their offices furnish to this otherwise undistinguished committee. With few, if any, exceptions, the other names represent gentlemen who are prominent and active members of the British Medical Association; the Central Medical War Committee meets at the offices of the Association; it is officered by members and officers of the Association, and issues its circular from 429, Strand, the grotesque statuesque and storied building of the Association.

Window Dressing.

Really the B.M.A. It must be clearly understood that, in spite of the presence of the co-opted members and the dignity which their names confer, the Central Medical War Committee is nothing more nor less than a committee of the British Medical Association, and has therefore no claim whatever to represent the profession. The British Medical Association has long since ceased to enjoy a reputation for good taste, good management or diplomatic dealing, and the sooner the military authorities inquire into its mandate and its capacity for organising the war services of the profession, the better for the success of such medical recruiting as is really required. Those authorities should at any rate take note that a repetition of anything in the nature of the senseless and unseemly threat above italicised will be promptly and bitterly resented by everyone to whom it is addressed.

Industrial Compulsion. If those who were responsible for this Chesterfieldian circular had given a moment's consideration to the state of the law on the subject, they would probably have hesitated before adopting their characteristic "British Medical" tone. For the reply of the resentful malcontent is both forcible and effective. The medical profession has been specifically excluded from the operation of the Act which imposes military service upon certain members of the community; but the Act does not debar a medical man from becoming a combatant. If he should become a combatant he cannot obviously be compelled to act in a medical capacity; for that would be in direct contravention of the pledge concerning industrial compulsion which has been repeatedly given by the Government.

The Attitude of Medical Association, which is com- the Profession. THE Committee of the British War Committee, would do well to ponder this point. The profession has proved itself actively patriotic and deeply conscious of its responsibilities in the present crisis; its members are sensitive to suggestion and, up to a point, exceedingly docile to persuasion. But, surprising as it may seem to the British Medical Association, many of them happen to be gentlemen, and gentlemen occasionally decline to be threatened or browbeaten or bullied without showing quite unmistakably that they resent such treatment. More especially are the gentlemen in question likely to resent such treatment at the hands of a self-elected bourgeois body, in whose organising and administrative capacity bitter experience has taught them to put no trust.

Combatants. AND the means of expressing indignation are to hand. Medical men of military age have only to enrol themselves as combatants, to dislocate the scheme which the military authorities at the War Office were foolishly beguiled into entrusting to the heavily mailed Mercuries at the British Medical Association, in the apparent belief that these criers of "havoc" really represented the profession. And, judging from the present tone and temper of the recipients of this

strange circular, if there is any repetition of the preposterous threat which it contains, this course will surely be adopted by many. The War Office would be well advised to look into this matter, and before it is too late to insist upon some sweeping changes in the personnel of the Central Medical War Committee. A better plan would be to dissolve the existing body and appoint an entirely new one.

A New Body. AND the expediency of appointing an entirely new body to manage the matter of medical recruiting is more real than may seem apparent. The circular seeks to hustle every medical man of military age into enrolling himself, here and now, with "our Committee." The note struck is one of extreme urgency. But let it be quite clearly understood that there is no urgency of any kind or sort. I have been shown a letter written by one of the four gentlemen who signed the letter to the *Times* (*vide* "Periphery" February 23rd), and who were received in audience by Mr. Tennant, Sir Alfred Keogh being present during the greater part of the time. From this letter it is evident that neither the one nor the other of these responsible and well-informed officials sees any present need for increasing the existing number of officers in the R.A.M.C. The letter further comments upon the fact that the Central Medical War Committee disavows the public statements of Sir Alexander Ogston, a prominent member of their own body, and that, in Mr. Tennant's presence, Sir Alfred Keogh disavows the statements made by the Central Medical War Committee.

Conflicting Voices. HERE, then, is an admirable instance of the compassless and rulerless condition in which the medical man of military age now finds himself. On the one hand we know, on unimpeachable authority, that the Director-General does not want any more medical officers, a fact which, on the face of the numbers already enrolled, must be perfectly obvious to any thinking person. On the other, we hear the shrill hysterical minatory shriek of the Central War Committee, which enjoins upon all and sundry the urgent necessity of immediate attestation. We have Sir Alexander Ogston, the President of the British Medical Association and a member of the Central War Committee, expressing views from which the Committee is in a hurry to dissociate itself. And finally, we have the Director-General declining to countersign the views of the Central War Committee. "Who, then, in this matter is Paul and who is Apollos?"

An Appeal. SIR ALFRED KEOGH deserves well of the profession. In circumstances of unexampled stress and difficulty he has steered the army medical ship with a degree of skill and efficiency which has compelled the admiration not only of those at home, but of those abroad. He is only human, but he has performed superhuman work, and has brought to his task the sympathy, tact and urbanity which so often characterise his race. He now owes it to himself and to his department to

shake himself free from this Central Medical War Committee, which, by cunningly confusing itself in the busy and preoccupied eyes of the profession with the medical authorities at the War Office, has succeeded in bringing discredit, unrest, and discomfiture upon the whole organisation of the profession for war purposes. And for their own sakes, and for the sakes of the institutions which they represent, the "distinguished front-page six" should make haste to resign before the Committee, with which they were beguiled into associating themselves, comes by its deserts.

State Medical Service.

AND the members of the medical profession, while smiling both at the cajolery and the threats of the impotent and impudent Central War Committee, would do well to consider the meaning of all these strange cross currents. There are not wanting those who see in the proper engineering of the present crisis an opportunity for dishing the medical profession, especially that portion of it which is associated with the Insurance Act. Dr. Welply and his union will do well to keep a sharp look-out on the situation. If panel practitioners can be induced to become members of the R.A.M.C. even for a year, a comparatively clear field will be opened to those who by stealth are seeking to establish a State Medical Service by which the profession would be sweated and the public underserved both in quantity and quality. That there is such a movement on foot there can be no shadow of doubt, and the sooner the panel men combine, and combine to snap their fingers at the British Medical Association and its War Committee, the better will be their chance of frustrating this sinister and dangerously well-organised design. I do not say that the members of the Central Medical War Committee are privy to this movement, but I do say most emphatically that, consciously or unconsciously, they are playing into its hands.

Combine.

FOR State Medical Service is not only in the building. It is already above ground. Here is a correspondent who writes concerning the Highlands and Islands Medical Service, upon the miserable remuneration of whose medical officers we commented a few weeks back. "None of us are enamoured of the scheme. It is a sort of semi-State medical service, with plenty of compulsion and no pension allowance. They give me £150 per annum to help me to keep a motor car or a motor bicycle, but I have to attend all distant insured people, all crofters and cottars, and all insured dependants, for the following fees:—First visit, 5s.; second visit, 2s. 6d.; medicines extra. I tried to secure that night calls should rank as extras, but this was not granted." And this is undoubtedly the kind of thing with which the profession all over the country will find itself face to face unless the present flank movement upon the panel practitioners first and the whole profession later is recognised and countered. Every doctor who is on the panel in any part of England, Scotland or Wales, should for his own protection immediately communicate with Dr. Welply, of the Panel Medico-Political Union, 47 Fleet Street. Union is wanted; the danger is a real one.

Report on Venereal Disease.

AND to strengthen the hands of the advocates of a State Medical Service there is the recently issued report by the Royal Commission on Venereal Disease. A *précis* of that report taken from the *Times* will be found in another column, and the whole report will be the subject of an article at an early date. The only point in connection with it

which concerns us at present is the recommendation "that every large local body (county or borough councils) should establish centres, completely equipped for all modern methods where *free* treatment should be available for all sufferers, irrespective of their actually living in the area. The cost of these clinics is to be borne, as to 25 per cent. by local rates, and as to 75 per cent. by Imperial funds." Outside the ordinary profession we have already the Public Health Service, the special service for the fight against tuberculosis, and the service of the Insurance Act. If in addition to these there are to be established a special service for the prevention of infant mortality and a special service for the suppression of venereal disease, the argument for organising the whole profession into various branches of a State service becomes overwhelming.

Organise.

A STATE Medical Service is not, in principle, by any means necessarily an evil thing; but its details should be a matter of negotiation, on something approaching to equal terms, between the profession and the State. It is only thus that the Profession can save its members from being sweated, and protect the public against insufficient and inefficient attendance. The State is already organised; it has its machinery. The Profession is at present wholly unorganised. It is indeed in a worse plight, for it is disorganised. A few years ago the British Medical Association succeeded in dividing it against itself, and is now clumsily continuing this destructive work. If the Profession does not cast off the shackles of this discredited body and rally to another union with new men and better methods, the powerful enemy which is creeping steadily and stealthily towards it will overwhelm it before it recognises the danger. Organise!

The Moral.

THE moral of all this, so far as the immediate present is concerned, is simple enough. A great many medical men of military age, who from financial, domestic, or other sufficient reasons would find it almost impossible to give their whole time to the authorities, have been seriously disturbed in their minds and consciences by the circular of the Central Medical War Committee. They imagine, naturally enough, that this circular represents a call from the Government, and they anxiously ask themselves and their friends what they are to do. The answer is quite plain. What they have to do is to put the circular in the waste paper basket and forget that they have ever received it. If any more circulars come from the same source they should be similarly treated. When Mr. Tennant and Sir Alfred Keogh deem it necessary to ask for more medical men—a very unlikely event—they will doubtless do so in language which is not only unmistakable but unthreatening. Until that time comes, those who have not attested need not attest, and those who have been frightened by threats may sleep peacefully in their beds.

WE publish this week the third and last French clinical lecture on Typhoid Fever, by Prof. Tournade, of Paris, the previous one being by Prof. Rimbaud, of Montpellier. The latter city has during the months of war, owing to the climate of the place and its seclusion gained for it a great popularity amongst the wounded and sick. Next week we hope to publish an article on the important subject of "Blood Pressure in Typhoid," from the pen of Dr. J. D. Rolleston, a Medical Officer to one of our large fever hospitals. SINAPIS.

CURRENT TOPICS.

Anti-Typhoid Vaccination.

THE still verdant subject of anti-typhoid vaccination continues, as of course all our readers know, to be one of very careful observation and unceasing discussion among the members of the army medical staff who have seen service at, or near, the Western front. It still also remains one of which the definite results, and the claims thereon founded, cannot be said to have been finally settled; for the conclusions are, admittedly, not "absolute," while the proofs are chiefly based on the data furnished by the truly terrible "science" of statistics, and the arguments which are displayed in support of the same are invariably found to be spiced with a leavening of the *argumentum ad hominem*. Nevertheless, the broad fact may now be safely admitted that the general results hitherto obtained have been decidedly encouraging—even after all necessary discount and desirable deduction have been duly dealt with in the interest of strict and unprejudiced reasoning. But it should always be borne in mind by the physician that the precise standard value of the degree of immunisation attained, or attainable, by the procedure of "anti"-vaccination cannot yet be definitely calculated by either the most observant of clinicians or the most mathematically skilful of statisticians. And having regard to the practically unlimited number of "variables" that must be taken into account in the integration of the promiscuous item furnished by the clinical data—which are unceasingly influenced by the mobile nature of the individual organism, and that of the type of disease and the influence of environing circumstance—it remains, in the light of our present knowledge, far less than likely that any *calculus* of human invention can ever be made applicable. Under such circumstances, we believe that it is more than merely justifiable to dwell on the emotional aspects of the question. Students of national, as well as those of medical, history will remember that dysentery was known a century ago—and during some centuries before—as "the scourge of retreating armies." Fatigue, bad food, bad water, and mental depression combined to relax the vessels of the splanchnic areas—and the resulting *anxiété épigastrique* which so descriptively presents the most prominent of the early results. The gastrointestinal congestion matured into (the then unlabelled) typhoid, or dysentery. And the fact that an (at least approximately) efficacious prophylactic has been employed by his medical guardian should always be present to the anxious mind of the weary soldier.

Medical Re-examination.

WE are suffering now from the effects of "rushing" the work of examining recruits. Many, very many, were in the crowds that came at irregular intervals insufficiently examined, with the result that some were passed into the ranks unfit for the work, and others rejected for trivial defects that should not have counted. The former are gradually being eliminated by the surgeons of the various units, who quite frequently have to send weaklings (we ourselves the other day saw a case of osteo-myelitis of the femur) to the nearest hospital for treatment or discharge. I cast no reflection on the recruiting examiners. They did well under overwhelming circumstances.

Now the tribunals are taking up the work of separating the fit from the unfit; but they, rightly enough, assume that the cases brought before them are medically fit; they judge from the social and family entourage of each candidate. A lad with

persistent incontinence of urine will have his claims to soldiering speedily settled by his influence on the Schneiderian membrane of his tent or hut-mates.

But in the case of those rejected for trivial conditions—e.g., minute varix in leg and scrotum, beginning hernia, etc., there is need for re-examination. The large leaven of civil surgeons who have gone to the help of the military surgeons have moulded the hard and fast lines that the War Office in its more limited experience had drawn on its, shall we say, semi-educated past.

The Wassermann Reaction in Syphilis.

AT a meeting on January 6th of the New York Academy of Medicine, a discussion took place on the "Serum Diagnosis of Syphilis." Dr. Sydney R. Miller, of Baltimore, spoke as follows:—"There can be no argument concerning the nonspecificity of the Wassermann reaction in the Ehrlich sense of the term. There is little danger of our seeing cases of yaws, recurrent fever and frambœsia in this part of the world, and practically the only other disease which has ever given us questionable results has been malaria; but this condition is always easily ruled out by finding the malarial parasites, and in a failure to do this, a course of quinine followed by a second Wassermann, will usually decide a doubtful case. As a result of the experience of five different laboratories, we have come to feel that an unequivocal positive Wassermann reaction, preferably with three, but not less than with two, in a *technique* suitably controlled, in which accuracy of result has not been sacrificed to delicacy of method, is clinically a specific evidence of existing syphilis. Our experience has been by no means unique, in that the Wassermann reaction has cleared up most difficult cases, and in a number of instances has clearly shown the casual or constant aetiological relationship of syphilis to the diseases under consideration. The point which needs the greatest emphasis, however, is that the closest co-operation must exist between the laboratory worker and the clinicians in the ward. The attempt to divorce one from the other is bound to lead to dangerous misinterpretations. Out of a series of approximately 1,500 Wassermann reaction tests in which the serum or spinal fluid was tested against three different antigens, the results were absolutely parallel in over 97 per cent. of the cases. In seven cases fixation was given alone by the cholesterinised antigen. In all of these a subsequent lumbar puncture revealed the fact that the individual was suffering from some type of syphilis of the central nervous system. This brings up two points which need particular emphasis: 1. A suspected spinal fluid should not be regarded as negative unless it is so when ten times the original volume suggested by Wassermann is used in the reaction. 2. Physicians should demand a report which clearly states against how many antigens and in what amounts a spinal fluid or serum has been tested.

Trinity College, Dublin, and Sir Patrick Dun's Hospital.

THE relations between Trinity College, Dublin, and Sir Patrick Dun's Hospital have recently come under the consideration of the authorities of the two bodies. It appears that some fifty years ago, when it was decided to enlarge the scope of Sir Patrick Dun's Hospital by making it a medico-chirurgical hospital instead of, as it had hitherto been, a purely medical hospital, Trinity College undertook to give some pecuniary assistance. This was given in virtue of the arrangement that the surgical teachers in Trinity College were to be the surgeons to the hospital. The form in which the grant was given was, however, peculiarly unfor-

fortunate. It was decided to charge each candidate for the qualifying degrees in medicine and surgery a fee for the *liceat ad eximandum* of ten pounds instead of the nominal fee previously charged. The fees thus collected were to be handed over to the Governors of Sir Patrick Dun's Hospital. This arrangement has lasted to the present. Recently, however, the point has been raised that it is unfair to many students who do not take advantage of the clinical teaching at Sir Patrick Dun's Hospital to be compelled to contribute to its upkeep. The Board of Trinity College has, too, been anxious to diminish the cost to a student of the medical curriculum, and it has decided to abolish the *liceat* fees. The Governors of Sir Patrick Dun's urge, not unnaturally, that at the opening of the hospital as a surgical institution, the College undertook a responsibility of which it cannot now divest itself, and have asked for a fixed grant in lieu of the fluctuating amount which accrued from the *liceat* fees. This matter is now under the consideration of the Board of Trinity College, and we hope that a satisfactory arrangement may be made. It would be unfortunate if the resources of the hospital, which have already suffered much from the depreciation of its landed property, were to be further injured. The Hospital has performed notable services to medical education and to the sick poor of Ireland, and its usefulness should be preserved and developed. Unfortunately, the settlement of the present difficulty is rendered more difficult by the complicated relations between Trinity College and the Royal College of Physicians—relations which bear directly on Sir Patrick Dun's Hospital. An agreement was arrived at ten years ago between the two Colleges to alter this agreement, but for some reason no steps were taken at the time.

Proposed New School of Dentistry in Dublin.

WE understand that the Council of the Royal College of Surgeons in Ireland has in consideration the establishment of a school of dentistry in connection with the School of Surgery already owned by the College. Both Trinity College and University College, Dublin, have schools of dentistry, but the College of Surgeons, although granting licences in dentistry, has not hitherto had a school. The two University schools have confined themselves to theoretical teaching, and students have resorted to the Dental Hospital of Ireland for their clinical and mechanical training. The Dental Hospital has, indeed, been the centre of dental education in Ireland, and it has done much to raise the professional status of the practice of dentistry. We understand, however, that the project in view of the Royal College of Surgeons includes the provision of opportunities of training in clinical and mechanical dentistry—that is to say, the establishment of a dental hospital or clinic. The difficulties in the way of the realisation of such a scheme are great, and require careful consideration before the College commits itself.

Scotch Vital Statistics.

THE sixtieth annual report of the Registrar General for Scotland, for the year 1914 contains the following:—

The estimated population of Scotland, which is based on the balance between the observed natural increase and the loss by emigration, is 4,747,167, and, while greater than that of the previous year (1913) by 19,035, is 13,737 less than the population in 1911, as ascertained by the last census.

Births registered numbered 123,934, and, though slightly more than in each of the years 1911, 1912,

and 1913, are less than those in other recent years. They are 9,591 fewer than in the year 1903. The birth-rate 26.11, though somewhat higher than in the years 1911, 1912, and 1913, is lower than in all other previous years. The births of illegitimate children are more than in the year 1913, but are less than the average during recent years. They numbered 8,879. The illegitimate rate 7.16 per cent. of the total births, is higher than in the previous year, but less than the mean of the rates of the preceding five years, and is greater than that of the preceding ten years.

The marriages registered number 35,049, which is more than in all previous years. The marriage rate was high. It was 7.38, and is higher than those of all previous years with the exception of 1865, 1872 to 1876, 1898, and 1899.

Deaths registered number 73,557, which is 488 more than in the preceding year, but is less than the average during recent years. The death-rate of the year was 15.49, and is higher than those of all years since 1909, but less than those of all other years. The infantile mortality rate was 110.6 per 1,000 registered births. It is more than that of the year 1913, but less than the average during recent years. Among causes of death of greater than average frequency were scarlet fever and diphtheria.

The Crichton Institution for Mental Diseases.

DR. EASTERBROOK, Physician Superintendent of Crichton Royal Institution, Dumfries, in his report for 1915 states that the private patients, certificated and voluntary, numbered 585 at the commencement, and 550 at the close of the year, or a decrease of 35. The rate-aided patients numbered 400 on January 1st, and 392 on December 31st, or a decrease of 8. The admissions numbered 203 (90 men and 113 women), this figure being 42 below the exceptionally high number (245) of admissions in 1914, but 10 above the average (193) for the previous six years.

Comparing the figures for 1914 and 1915, there was a decrease of 42 in the admissions of 1915. But as the admission rate was unusually high in 1914, the year of outbreak of the great war, and as the admission rate of 1915 was above the average for the six years preceding 1914, the Medical Superintendent does not feel justified in drawing conclusions as to any special connection between an apparent but not real lowering of the admission rate of 1915 and the influence of the war. Many mental hospitals in the country report a lowering of their admission rates since the onset of the war, but this has not been the experience of the institution, at which the admission rate has been higher than the average for several years previous.

An analysis of the histories of the 130 receptions showed that, in addition to the possession of an unstable nervous system, inherited or acquired, the principal exciting causes of the mental illnesses included:—Worry and anxiety and allied psychological factors, 25 per cent.

LORD KNUTSFORD, better known as Mr. Sydney Holland, chairman of the London Hospital, has met with a serious motor accident, sustaining head injury and general bruising. He is reported to be progressing favourably.

At a meeting of the Market Harborough Guardians on February 25th, the Clerk said their medical officer (Dr. Thomas) had already gone, and out of seven medical officers employed by that Board, five had already joined. He thought their Board had done all it could to spare their medical men.

FRENCH CLINICAL LECTURE

ON

SUBJECTS OF ANTI-TYPHOID VACCINATION; TYPHOID FEVER OCCURRING IN THE ANTI-TYPHOID VACCINATED.

By M. ANDRE TOURNADE,

Medecin-Major, Professeur Agréé of the Faculties of Medicine, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE series of cases of typhoid fever which I am now about to discuss have been observed by my *confrères* and myself in the No. 13 Hospital at Verdun in the period ranging from December 1st, 1914, to February 15th, 1915. The items of the complete series are classified in the subjoined table, which also presents a summary of the most important features and results:—

	Number of Inoculations.			Total.
	2	3	4	
Total number of cases observed	76	36	30	142
Number of cases received during the three-week period after inoculation	21	4	1	26
Number of deaths	6	4	0	10
Mortality: 7.04 per cent.				

I now hasten to indicate to the reader how the results thus tabulated lend themselves to instructive discussion, but I will just point out at once that even the criticisms which they may elicit, and which may be based on the presentation of facts here offered, must inevitably tend to the more precise definition of the conditions which should always be required in the preparation of corresponding documents; before final estimation of the degree of credit that may justly be accorded to the arrangement of the perspective, and the assumed reliability of the conclusions.

The diagnosis in every one of the vaccinated cases here referred to has been purely clinical—*not bacteriological*—and, in virtue of that very fact, it, wrongly indeed, confounds under the same rule of conduct with typhoid fever properly so-called—affections specifically distinct, and against which typho-vaccination presents no immunising influence whatever. So far, indeed, as we may be permitted to draw conclusions from analogy of clinical facts and features, the greater number of those patients were infected by the *Bacillus paratyphosus B*, or other germs of even less importance; but a minority by the Eberth bacillus. Anyway, this conclusion arises from the results of the researches carried out in the various laboratories of the first army, and in connection with subjects of the same rank; and it is in the same sense that the results of the investigations made by MM. Lippman and Penan at the Hospital No. 13, since February 20th, 1915, must be admitted to plead on their own behalf.

There can be no doubt of the clinical fact that the great majority of the vaccinated patients, who had apparently contracted typhoid fever, were in reality suffering from paratyphoid; the proportion being about 75 per cent. But, at the same time, it cannot any longer be disputed that 25 per cent. of the vaccinated cases did actually present the authentic Eberthian infection. Are we accordingly to conclude—as do certain physicians who are mentally devoted to final solutions of the most simplified type—that anti-typhoid vaccination has really failed to fulfil the promises made in its behalf?

Before pronouncing a definite answer to this

important query, we should carefully pass once more through the critical filter the observed facts of every individual case in which the Eberthian infection has been authenticated, and thoroughly examine the record of the conditions under which the inoculation had been carried out in each instance. Let us then ask the question every time: Does this case present a satisfactory record of the fulfilment of all the requisite conditions?

Now, on proceeding to carry out this inquiry, we soon come to ascertain the fact that a certain proportion of the total number of vaccinations have necessarily proved powerless as regards the conferring of the desired immunity, for the plain reason that they had been carried out on *subjects already infected*—that is to say, during a period of more or less latent incubation. The reality of this very important fact is established by double proof: First, the unquestionable record of the lapse of an interval of less than three weeks between the date of the vaccination and that of the onset of the first symptoms of the fever. Second, the frequency of abnormal temperatures occurring among the soldiers who had just returned from the trenches and then presented themselves for anti-typhoid vaccination. On the dates November 5th and 9th, 1914, I had the rectal temperature taken in a series of 749 soldiers before injecting them with anti-typhoid vaccine, after deciding with myself to adjourn the procedure in all the cases which should present a temperature above 38° (100.4° F.). Now, no less than 67 of the total number of that series of cases were found to present this abnormal thermometric condition. They were thus classified:—

34 presented a temperature ranging between 38° (100.4° F.) and 38.4° (101.12° F.); 17 between 38.5° (101.3° F.) and 38.9° (102° F.); 9 between 39° (102.2° F.) and 39.4° (103° F.); 7 between 39.5° (103.1° F.) and 40° (104° F.), and upwards.

Now, it is absolutely certain that without the physical proof supplied by the evidence of the thermometric test, those men would all have been regarded as of normal condition, and accordingly registered as duly inoculated. They would also have presented in every instance a strongly pronounced febrile reaction, of which the vaccine would have been wrongly obliged to bear the whole responsibility. But there is even more significant evidence of fact still to be revealed. During the days next following, 16 of that series of 67 men had fallen ill, and *eight of the cases proved to be typhoid fever*. If the vaccination had been carried out on the members of this last group, it surely could have played but a doubtful part in antagonising an infection already realised, and would inevitably have been once more marked down as a failure—under most fallacious evidence.

Thus we have succeeded in eliminating from the record of the procedure those cases in which the vaccination seemed to have proved inefficacious, simply because it has been carried out too late, and was accordingly unable, as sometimes occurs in the

practice of anti-rabic immunisation, to outrun the velocity of the previous infection; indeed, after evidence of the latter had been attained, the practice of vaccination should, according to our principal physician, M. H. Vincent, be absolutely forbidden.

But we should not, on the other hand, even with the fullest impartiality, ever take into serious consideration the records of cases of failure to establish immunity which were merely due to the adoption of a procedure carried out with a wholly irregular *technique*; insufficient number of injections; too long an interval between the successive punctures; employment of vaccine of inferior quality, or spoil by long keeping; etc. Not one of those factors must be regarded as negligible, and they have many times intervened in the inevitably precarious conditions under which the procedures of attempted immunisation have been carried out among our soldiers at the front; where the vaccination had to be hurriedly performed in the interval between two sojournings in the trench, or between two successive assaults.

And if there still subsists, after all those legitimate and necessary eliminations, an indisputable record of the occurrence of some cases of genuine Eberthian infection occurring in subjects who had been vaccinated with all the precautionary details of apparently rigid orthodox practice, what conclusion must necessarily be drawn from this statistical fact? The true reply evidently is that the degree of protection which is conferred on the subject of typho-vaccination is not absolute, not a prognostic item of mathematical certitude, any more than is that of the immunisation—which is nevertheless unquestionable—conferred by a first attack of typhoid fever.

Finally, I would here add, in accordance with the evidence offered by the collective experience furnished by the results of my personal observations, that if the procedure of anti-typhoid vaccination does not absolutely secure preservation from all future attack, there is still a degree of advantage, when one is attacked by the typhoid infection, in having been previously vaccinated. For, in the great majority of those so treated, the disease passes through a benign course, and the recorded mortality is but 7 per cent.; which surely offers a convincing contrast to the 14 per cent. mortality of the cases occurring among the non-vaccinated; while, in addition to these statistical facts, it should be permanently remembered that the items of that record of reduced mortality are drawn only from the list of those patients who had been inoculated but two or three times; not a single one of those who had received the full number of four inoculations has, so far as we have had an opportunity of ascertaining, succumbed to a subsequent attack of typhoid fever.

Mr. Arnold Morley, M.P. (Liberal) for Nottingham 1880-5 and the Eastern Division 1885-95, Patronage Secretary to the Treasury 1886 and Postmaster-General 1892-5, son of the late Samuel Morley, M.P., left £2,500 each to the General Hospital, Nottingham, the Convalescent Homes Association, Nottingham; and the Children's Hospital, Nottingham; £1,000 to the Women's Hospital, Nottingham and £500 to the Anglo-American Hospital, Cairo. He also bequeathed £1,000 to David Morgan Beddoe, F.R.C.S., of Cairo, "who does so much for the people among whom he lives and works."

DR. AYLMER MAY, who was principal Medical Officer to the Forces in Northern Rhodesia, is to act as assistant in France to Colonel Sir Alnroth Wright

ORIGINAL PAPERS.

THE TREATMENT OF GUNSHOT WOUNDS.*

By SIR BERKELEY MOYNIHAN, F.R.C.S.,
Professor of Clinical Surgery in the University of Leeds.

SIR BERKELEY MOYNIHAN, F.R.C.S., in introducing the subject, said the problem of the treatment of gunshot wounds was one which had been profoundly altered, if indeed it had not been radically modified, by the experience derived during the present campaign. The new and unexpected features were dependent upon a set of circumstances each one of them different in kind from anything which surgeons had known before. The character of the bullet in respect to its mode of flight, its velocity, the damage it inflicted on the parts, the quality of the infection derived either from the earth or from the patient's clothing, was far more virulent than anything which surgeons in the present generation had had any experience of. And, in the earlier stages of the war at least, the conditions of the patient, in respect of fatigue and anguish, were such that he fell a very easy victim to the bacterial onslaught, which was one of great ferocity. In the early literature of the war, a good deal was said in regard to failures—failure of the antiseptic system, failure of the aseptic system—and on the upheaval which threatened the position which Lister had held in all minds; all those things were spoken of with a certain amount of acrimony. One of the earliest tasks which he set himself on returning from France was to once again go over Lister's papers, to see how he had met the concrete problems with which he was faced fifty years ago. Lister, of course, stood in need of no defence to-day; and even if he did, the best defence was to be found in those papers just mentioned. The new set of circumstances had reference partly to the flight of the bullet. The bullet had several different movements: a forward movement, a rotation round its longitudinal axis, and a curious movement, which the French called a *mouvement de bascule*, which, he was told, those standing behind a shell in its flight could see. The apex of the bullet travelled steadily, while the base twisted round in a circle of gradually diminishing extent until it came to an end at about 800 yards. The soil on which the campaign was still being fought was some of the most highly cultivated in the world; for generations it had been heavily manured, and therefore contained the organisms one would expect to find in tæcal matter from horses, cattle, pigs and poultry.

In such a discussion as this, one must remember the quality of the wound inflicted, and the kind of bacterial implantation in the surface wound. When a bullet struck soft tissues, it was probably arrested at its tip sufficiently to allow the base—heavier and with a greater momentum therefore—to catch up with the apex, so that a rolling action of the bullet ensued, giving an explosive effect. The muscles torn retracted with unequal strength, resulting in little recesses and cavities being formed in the wound. Hence little lakes of serum were shut off completely, and if the implantation of bacteria had occurred there, a very prolific growth of them took place. The projectile imparted some of its terrific velocity and force to substances which it struck, so that portions of bone which received the impact themselves became in a sense projectiles which were hurled into the surrounding tissues. The sodden clothes of the soldier who had been on such rich soil carried microbes, and portions of

* Paper opening the discussion of the subject at a meeting of the Harveian Society of London, February 24th, 1916.

clothing carried in by the bullet impregnated the wound with those organisms. In treating such wounds, the petty little methods in use for civil cases before the war were utterly inadequate. In pre-war days, it was common to apply tincture of iodine or carbolic acid to the wound; but so little effect was produced by them in these patients that by the time they reached the base hospital it was impossible for the surgeon there to say what application, if any, had been made to the wound at the field ambulance or clearing-stations.

The question of gunshot wounds should be approached from two points of view. The first was the preventive treatment of infection of wounds, *i.e.*, the prevention or control of infections at the earliest possible moment after the infliction of the wound. The second was the abolition, or reduction, of an infection which had already been set going. Before considering those aspects, however, there were certain preliminary matters which it was well to clear out of the way.

First, with regard to the excision of gunshot wounds. This, of course, was the ideal method. If an infected wound could be excised, so that only clean raw surfaces were left, which it was safe to bring together by suture, then the wound would heal by first intention; it was the kind of wound which the surgeon made deliberately at an operation. But in the circumstances prevailing, it was impossible to think of being able to do this in most cases, though it had been done in the case of many penetrating wounds of the knee joint, of the scalp, and of the abdomen. It was a method which Colonel Gray, now at Rouen, had practised in many cases, and that surgeon placed much reliance on it.

He next wished to insist that all wounds, wherever they occurred, must be treated with a certain ritual. The skin must be cleaned, loose fragments of clothing, coins which had been carried in from the pocket, fragments of bullet, bits of leather, should be taken out at the earliest possible moment, and efficient drainage should be established. He believed that too little regard was paid to the adequate preparation of the skin. The favourite method of preparing the skin around a gunshot wound was to paint it with iodine. He had seen tincture of iodine painted over dung and dry earth—rather imperfectly painted, as a rule—and an operation carried out on the parts in the firm belief that something effective had really been done to secure sterilisation of the skin. To sterilise skin was always a difficult matter; to keep skin sterile for half an hour was an almost impossible matter. And one of the most ineffective methods of preparing the skin for operation or when a gunshot wound was to be treated was the painting of it with any form of iodine, of any strength, with any degree of frequency, and under any circumstances whatever; and he wished to denounce as strongly as he could the use of iodine for the purpose of applying it to the skin in surgery; it was an entirely ineffective and futile method. The worst of it was that it bred a certain kind of superiority in the mind of the surgeon. A surgeon who could lightly perform an act which he believed to be of value was apt to think that other acts could be performed easily during the course of the operation. It was a very difficult thing indeed to do any surgical operation perfectly, so far as the *technique* was concerned. Never for an instant was a surgeon entitled to relax his supervision of every detail relative to the antiseptic *technique* of an operation. And if by the application of an insufficiently effective substance like iodine to the skin he thought he had done something which was of value in the ritual, it was apt

to affect his whole attitude towards the future stages of the operation. The skin, therefore, in cases of gunshot wounds should be first cleaned. And it was well to have it cleaned with something which was easily available. There was always plenty of petrol about, and that was useful for the purpose of getting the skin socially clean. Surgical cleanliness was brought about by the use of an antiseptic. The best was one which ought to be easily accessible, namely, Dakin's solution.

The third point to which he wished to refer was immobilisation of the wounds. That was a point which he felt sure was very ill-considered in the majority of cases. If a patient received a fracture, whether of the arm or of the leg, in many cases at least some apparatus for immobilisation was applied. It was equally important in cases of severe wounds of soft parts. The absence of motion in a limb which had suffered a severe injury increased the comfort of the patient, and considerably diminished the risk of the extension of the infection throughout the wound.

He now came to the question of the treatment of the gunshot wound under the two headings he had indicated. The first was the control of infection from the earliest possible moment. That might be called the abortive treatment of infection received in a gunshot wound at the time of its infliction. In the earlier stages of the war, as he had already said, carbolic acid and tincture of iodine, and various other substances, were used, in the hope of producing some sort of sterility in gravely infected wounds. Those measures, as many knew, were utterly inefficient. The reason was that our standard of antiseptics was quite different from what it was supposed to be. For years, ever since Lister found that at Carlisle they were using a crude form of carbolic acid to disinfect sewage, it had been the standard of an antiseptic for the surgeon. The surgeon had been in the habit of speaking of pure carbolic as something all-powerful, capable of controlling or annihilating the infection produced by any organism. As a matter of fact, pure phenol was an extremely feeble antiseptic compared with some antiseptics now in use. Therefore when blaming carbolic acid, it was well to remember that the surgeon was now being faced with problems arising out of the war quite different from those which had been confronted in civil practice, in which very grave infections had been, for years, almost unknown. The antiseptics which he thought of value were the hyperchlorite solution, named "Dakin's solution," which was made, first of all, in the University of Leeds, of which Dr. Dakin was an old student. He was sent over from the Rockefeller Institute, where he was with Alexis Carrel, to carry out researches in the French hospitals. He (the speaker) met him within a day or two of his coming to Europe, and heard his views with regard to the chance of the discovery of an antiseptic of better value. It was not long before they began to make, under his formula, "Solution 30," which was Dakin's solution. This possessed a bactericidal value far greater than that of carbolic acid. It was of no use to test the power of antiseptics in ordinary watery solutions. It must be tested in the presence of either serum or pus. Tested in the presence of serum, Dakin's solution had a bactericidal value about thirty times as great as pure carbolic. A commencement was made with Dakin's solution very early, and he (Sir Berkeley) had made a good many investigations in regard to it from the clinical standpoint, and also some from the bacteriological, during the last few months. Dakin's solution was very cheap, easily made, and was very

diffusible throughout the wound. It possessed a really remarkable power of clearing away dirty sloughs from a wound. But the solution needed to be applied in the proper manner. Surgeons had been brought up on the idea that the ideal surgical dressing consisted of some gauze, a certain amount of wool, and a bandage. When that kind of dressing was applied to the ordinary gunshot wound of war, one saw, on taking it away, a thick layer of pus, even an hour or two after applying it, on the surface of the dressing. What had been done, in applying that so-called antiseptic dressing, was to poultice the wound with pus. Obviously, that was not the best way of dealing with a wound, and Dakin's solution must not be so applied. The wound should be packed rather loosely with gauze, which could be frequently made wet by the application of fresh quantities of the solution. The various ways of doing that were simple. One of the ways, introduced by Carrel, was to have tubes of small size, in which were many perforations, wrapped round with Turkey towelling. These were pushed into the furthest recesses of the wound, and into them some of the solution was injected. It diffused itself throughout the wound, penetrating to the deepest recesses. Another method was to have strings dependent from the wound, which strings sucked up the liquid, whence it was conducted similarly to all parts of the wound. The best plan, he thought, where the wound was in a situation which allowed of it, was to have a loose packing of gauze and to send a nurse round every hour armed with a Florence flask charged with the solution, from which she replenished the cases with the solution. Underneath the limb was placed a photographic dish for the reception of the excess fluid and the discharges from the wound. Dakin's solution must be used fresh, not more than five days old; and it must not be heated before use. It was a little apt to irritate, and that irritation seemed greater in some parts of the world than in others. Dakin suggested that it was probably because the bleaching powder from which the solution was made was of different quality in these various places. He (the speaker) thought also that as it had such tremendous chemical power some interaction occurred, especially if other antiseptics had previously been used in the case, and irritable products ensued. In view of this, it was advisable in all cases to protect the skin. The great point was never to apply the ordinary civil dressings which were customary before the war.

Dr. Dakin had now made a newer antiseptic, which he called "chloramine." That was, approximately, five times as strong as the hyperchlorite—in other words, 150 times as strong as pure carbolic acid, tested in conjunction with serum and pus. It was an extremely diffusible substance, and it had been a little difficult to find the best way of utilising it. He thought, however, that the right method had now been found. It was suspended in gauze, and this gauze, when packed lightly into a wound, diffused this very strong antiseptic steadily throughout the wound. It had only been in use for three or four months, but so far the results showed that it was an exceedingly powerful antiseptic, much stronger than anything which had been used by them before, and its power of cleaning a wound was greater. Unfortunately, there had been some difficulty in getting it, because the necessary substances were not easily obtained; but recently two or three tons had been procured, and he therefore hoped it would be generally obtainable. He had just heard that the name of it would have to be changed to Tolamine, because twenty or more years ago a patent-medicine vendor in America gave the same name to a cough mixture.

The treatment of a gunshot wound, therefore, immediately after its infliction should be treatment directed to the abortion of the infection by the application, at the earliest possible moment, of the strongest antiseptic obtainable.

The question here arose as to whether Wright's method of hypertonic saline was of any value in the early stages after the infliction of such a wound. Just a year ago he (the speaker) was with Sir Anthony Bowlby at the front, and he saw a very great number of patients brought into field ambulances and stations, and he could vouch for the perfect accuracy of Sir Anthony's description of the men so brought in: they were weary beyond endurance, and the moment they were brought in they fell asleep, and it became difficult to rouse them, either to take beef tea or to smoke the inevitable cigarette. They were cold, and often they had poor, feeble pulses, and they looked very pale. If at this stage Wright's method was applied, depending as it did on causing a profuse outflow of serum, it was quite certain that wounds inflicted upon people of this kind could not be compelled at first to discharge serum. The blood-pressure must be very low, the pulse flickering, and it would be found almost impossible to arouse a flow of serum from such a patient. Even if it could be done, he thought it would be the worst thing for a patient in that state, from the point of view of his general condition. Taking into account the general principles he had mentioned, he thought the best thing which could be done was to apply as soon as possible the strongest procurable antiseptic, in a form which permitted of free diffusion throughout the wound, though not too rapidly. He did not think the task of disinfecting wounds from the beginning ought to be very difficult, because the work of Alexis Carrel had shown that when smears were taken from these wounds within half an hour of their infliction, it might be necessary to search through several smears before finding organisms. It was only because the organisms were very virulent, or the nutrient medium most suitable, that the cases showed such rampant processes of putrefaction. Carrel's work seemed to show that there should be no difficulty in aborting an infection if adequate means were taken early.

The next question to be considered concerned the treatment of infections when such had been thoroughly set going in a wound. In most of the cases of wounds such as were seen in England, where suppuration was already ablaze, and when all possibility of prevention was passed, the question became one of deciding what was the best method of controlling, and eventually removing, the infection. This seemed to him the right stage of the discussion to touch on Sir Almroth Wright's hypertonic saline method.

The principle which Wright asserted was that by the application of very strong saline solution to the surface of a wound there was caused an outflow of large quantities of serum, this serum having bactericidal properties, so that organisms in the wound were attacked and destroyed. There was no doubt that, properly applied, Wright's method produced an extremely copious outflow from the wound. So great, indeed, was the drainage from an extensive wound that patients complained seriously of thirst, and consumed large quantities of water. If such drainage occurred early after the receipt of the injury, he thought it undesirable to apply it, from the standpoint of the patient's general condition. Wright's solution certainly cleaned a wound, gravely infected with organisms and producing pus in large quantities, quicker than did any other application; the granulations then began to grow with health, and a condition was produced in the wound such as he thought Solomon must have

had in his mind when he said, "The blueness of a wound cleanseth away evil" (Prov. xx., 30). There were certain disadvantages in Wright's method. If the application were too long continued, there was a tendency for the granulations to bleed and become oedematous. And Wright's method, tested bacteriologically, was ineffective to kill the streptococcus, which was the hardiest and tardiest of all the wound organisms. In the case of wounds in France, however freely they suppurated, they rarely found the streptococcus present. At the end of three or four days after the application of Wright's method, all the organisms had gone with the exception of the streptococcus; and that was one grave objection, that however carefully the method was applied, there was no power in it to kill the streptococcus. When the bleeding of granulations occurred, it was better to stop the method and apply something else. Wherever possible, the edges of the wound should then be drawn together, by sutures or plaster, and then even the most unlikely-looking wound would sometimes heal up rapidly. A variant of Wright's method had been introduced by Colonel Lawson. Instead of putting the gauze on and constantly saturating it from a Florence flask, he used a gauze wick in which tabloids of saline were wrapped. It was only a different method of application. He had used it himself, and he found that the patients complained of burning and smarting; therefore he had tabloids made with chloraltona, and with this analgesic the patients seemed to be more comfortable.

Another method which he had seen tried was that introduced by A. E. Morison, of Newcastle, namely, sulphate of magnesium with glycerine. He could bear witness that the claim made by Morison for this method was a just one. The wounds so treated were vivid with health; and the great advantage possessed by this method was that the streptococcus was killed often by the fifth day.

The method of treating a heavily infected wound with antiseptics was utterly futile before this war. They were syringed out with some sort of lotion, and a dressing was put on. That was ineffective, and such measures were ridiculously ineffective in the case of these campaign wounds. But treatment on the lines already mentioned with Dakin's solution, or with chloramine, quickly brought health back to the wound. On the whole, he had a preferential regard for Wright's method in all cases of profusely suppurating wounds, such as were seen in England, especially in the earlier stages.

One matter which was of great advantage in the treatment of gunshot wounds was getting the patient into the open air. Three or four days ago he was inspecting the hospitals at Sheffield, which would scarcely be called a health resort. He found sixteen patients in a row, who had been out of doors day and night, and they were cases of most grave infection. He gave them every opportunity of saying they were miserable and would be happier inside, but they said they were comfortable and would not go inside if they could avoid it. In France, Major Adye-Curran had compelled him to believe that it was a great advantage to patients suffering from heavy infection to have them out of doors, and wherever possible, to have the wounds exposed to air and sun. And in the retreat from Mons, where the worst cases came from, he took off the dressings from the very bad wounds, and exposed them to the sun. When it seemed that the patient must die, owing to the severity of his infection, a remarkable change came over him when he was exposed to sun and air, the latter even all night, even in a rigorous climate. Under such circumstances patients ate better—if that were possible—slept better, and altogether enjoyed themselves more than when kept in the ward. In deciding

whether to take a patient who was very septic into the open air, no regard need be paid to his temperature chart. The value of such exposure to the air he learned many years ago at the Johns Hopkins Hospital; it was one of the many things the profession owed to Halstead.

With regard to vaccines, he spoke of them with hesitation in this connection. The differences of opinion among physicians with regard to this matter were such that one felt timorous about even mentioning the subject publicly. The disparity of view was possibly traceable to the opinions not having been based on similar events. He felt, however, that surgeons had not given vaccines quite a fair trial. Tuffier, of Paris, one of the greatest of living surgeons, expressed the opinion—with all a Frenchman's elegance and a Scotsman's confidence,—that vaccines were not of the slightest use in surgical cases. Were vaccines of value when used as prophylactic agents? If the hypothesis which Wright had expounded were true with regard to the action of vaccines, that they did something to fortify the power of the serum against organisms with which it had to fight, then Wright's vaccine treatment and Wright's hypertonic salt solution treatment would seem to be reasonable as methods of dealing with wounds. So far as prophylaxis was concerned, he did not know that the method had been put into practice. Sir Watson Cheyne suggested, in a paper in the *British Journal of Surgery*, that bacteriologists might now well be employed in trying to raise the defensive power against organisms encountered in this war in the case of all the new recruits. However, the fact remained that the great scientific triumph of this war was that which Sir Almroth Wright had won in connection with typhoid vaccines; and if there was hope of even remotely approaching that, a very thorough trial should be given to preparation by vaccines of soldiers who were to fight in this war.

NOTES ON TWO CASES OF ANEURYSM DUE TO BULLET WOUNDS.*

By C. ARTHUR BALL, M.D., F.R.C.S.I.,
Surgeon to Sir Patrick Dun's Hospital.

LIEUTENANT F. T. was admitted to King George V. Hospital with an aneurysm of the femoral artery. He gave the following history:—"I was wounded on April 25th at St. Julien. When firing a machine gun a bullet hit the gun, the bullet was smashed to pieces, and the pieces were deflected downwards into my legs and right elbow. Five or six pieces were afterwards picked out with forceps, having lodged just under the skin. Two large pieces entered my right thigh, and remain there still. After being hit I walked away about thirty yards and asked a man to bandage my leg. I must have lost consciousness, as I do not remember the man finishing the dressing. After a time an officer came to see me and tied something tightly round my thigh. Was carried to a dressing station about two hours after being hit, and went from there to Poperinghe Hospital an hour or so later. Felt very weak and thirsty; was given an enema saline, I think. Felt better next morning, went by train to Boulogne on April 26th; crossed to England on April 27th, and went to hospital in London. Wounds healed cleanly. After about 12 or 14 days I noticed a pulsation over one of the wounds, and pointed it out to my nurse, who said it was the femoral pulse. From the way she spoke I thought it was nothing out of the ordinary, so did not bother any more about it. Had a slight rise of temperature, about

* Read before the Section of Surgery in the Royal Academy of Medicine in Ireland, on Friday, December 3rd, 1915.

100° every evening, for about twelve days after being hit. Left hospital and went on leave about May 19th. Felt no pain in leg except an occasional twitch. Noticing that the pulsation still went on, and that the swelling got very slightly larger. I did not take any very violent exercise during my leave, nor do a very long walk. Appeared before a medical board on July 10th, admitted to hospital July 12th."

On Examination.—A pulsating swelling about the size of a bantam's egg was present over the centre of right thigh, just over the femoral vessel at the site of one of the wounds. Pressure on the femoral at the brim of the pelvis stopped the pulsation, and the swelling rapidly diminished in size. It appeared as if the aneurysm was quite superficial and only just under the scar. There was no pulsation in the veins of the leg. X-ray examination showed two small pieces of metal in the thigh, one just at site of aneurysm. As the swelling was increasing in size and felt as if it might readily burst through the scar, operation was advised.

Operation.—An incision was made over the femoral vessel above the pulsating scar, the superficial femoral was exposed, and a Crile's clamp applied so as to control the vessel. The incision was then prolonged downwards past the aneurysm, and the artery exposed below, another Crile's clamp was used to control the artery here. The anterior part of the sac was then dissected free, and it was found that the sartorius muscle completely covered the sac (so that the apparent very superficial feel of the aneurysm was more apparent than real). The sac was isolated as much as possible, with the view of ascertaining if the hole in the artery could be sewn up, as in Matas' operation. Some laminated clot was removed, and it was found that the sac extended as far to the posterior as to the anterior side. Some slight bleeding of bright colour came from the sac in spite of the main vessel being secured above and below. As the entire artery was involved there was no question of suturing the hole in the vessel. The question of excision of the sac was then considered, but it was thought inadvisable, as the sac was so adherent that it would have meant injuring the vein. The lower opening of the artery into the sac could not be made out. The artery was then tied with a double ligature of chromic catgut above the sac and below, owing to the slight bleeding the sac was sutured up and the wound closed. The fragment of metal did not obtrude itself, and was not searched for.

The following morning the foot was warm, no pain was felt, and pulsation was present in the dorsalis artery. From this it seems likely that the fragment of bullet had penetrated the artery, and the lower lumen had become obliterated, and the collateral circulation previously established. The wound healed *per primam*, and the patient was discharged from hospital on August 1st, 1915.

I saw him again three months later. His leg was quite comfortable and strong. The only thing he noticed was that after walking hard for a few miles, his calf pained him. Possibly, for active muscular work, the circulation was not yet able to supply the muscles with sufficient blood.

The second case was an aneurysm of the axillary artery. Private W. was wounded at Loos on September 25th, 1915. When charging, a bullet entered just below the outer end of his right clavicle. Immediately lost all power of moving his right hand and arm. He states that he lost a great quantity of blood. There was no exit wound.

On Examination.—When admitted to King George V. Hospital no exit wound could be found. He had complete paralysis of the right arm; sensation was present in the hand and arm, except over

the area supplied by the ulnar nerve. He complained of very severe pain in his hand.

It was thought that the bullet was lying near the wound, and an X-ray was taken of the shoulder. To my surprise this did not show the bullet, but showed a comminuted fracture of the surgical neck of the humerus (the bullet was subsequently located in the thorax). The wound healed in a few days, and the arm and shoulder were put up in plaster, with the arm abducted so that if, as was thought likely, an ankylosed shoulder resulted his arm would be in the most useful position.

The plaster was left on for three weeks, and during this time the nerve pain referred to in the hand became gradually less, but at times it was quite severe. The only movement present was a slight power of supinating the hand.

When the plaster was removed a pulsating swelling was present, evidently about the third stage of the axillary artery. The swelling was about the size of a small hen-egg. When the subclavian artery was controlled the swelling diminished to about half its size, and when the artery was released three or four beats of the heart filled the swelling to its original size. The question of treatment lay between ligature of the third stage of the subclavian artery and direct exposure of the axillary vessel, but it was thought that, owing to the extensive matting of the tissues, which appears a constant factor in this type of traumatic aneurysm, ligature of this vessel would have had considerable operative difficulties. This was done and without any advantage to the patient. Ligature of the third stage of the subclavian was therefore decided on. No alteration in the temperature of the limb was subsequently observed, and since the operation, about three weeks ago, there has been no return of pulsation in the swelling, which has almost disappeared. He is now able to move his fingers, and power seems returning every day.

These two cases of traumatic aneurysm have several points of interest. One is that they came on slowly, and in the first case caused no symptoms, so that such cases may readily be overlooked. The first case would not have been noticed if the officer had not come before a medical board, he believing himself quite fit. In the second case my attention was directed chiefly to the fracture, and as Major F. C. Purser was at King George V. Hospital seeing another case, just after the plaster had been removed, I asked him to look at the paralysis in the arm, and he first detected the aneurysm. In this case from the entrance wound and position of the bullet it was hard to see how the humerus could have been broken, unless the fracture was caused by his falling when shot. The patient himself is positive this did not happen, and the appearance of the fracture was against this. The aneurysm was probably caused by an injury to the axillary vessel from one of the sharp fragments of bone.

CONSERVATION OF VISION AND PREVENTION OF BLINDNESS.*

By G. E. DE SCHWEINITZ, M.D.,

Philadelphia.

In a recent novel occur these words: "The light was going fast. . . . With the splendid (I would amend, the foolish) disregard of youth for its most precious gift, Elsa strained her eyes to thread her needle once more." A great schoolmaster, rich in the wisdom of ripe experience, has said: "More eyes are harmed in the home than in the school." Three

* Delivered before the National Committee for the Prevention of Blindness, November 4th, 1915.

children sat on the sidelines of a playground, blinking pitifully and peering uncertainly at their comrades romping over the field. Asked why they did not join the merry throng, they replied, "We can't see well enough to play that game." A group of men and women from the better walks of life watched a company of children at play, inmates of a great institution, all blind, and one-fourth of them the subject of blindness from a cause by which they need not have been enslaved. Voicing a popular belief, one spoke thus: "Isn't it pathetic, and yet how cheerful they are; how sweet their dispositions?" Shall such sweetness, such cheerfulness, I ask you, be purchased with the coin of blindness?

Two years ago Henry Copley Greene, writing concerning the subject which interests us, issued a "challenge to the professions"; to-day I would in like manner (I wish I were the master of Mr. Greene's incisive language) issue, not a challenge, but an appeal, to society, and ask five questions: Shall Elsa be allowed to trifle with her most precious possession? Shall our homes be permitted to disregard the laws of visual hygiene? Shall children, and those children of the larger growth—men and women—remain on the sidelines because they can't see well enough to play that game, the great game of stirring life with its joy of untrammelled effort? Shall they not have a game which they can play? Shall we of these better walks of life pursue our ways in snug contentment, and permit the preventable causes of blindness to continue their black business and ever add to the roll of their victims?

Of the blind population of our country, in general terms these are the component parts: Those who are really blind, for whom the light has gone out; those who still perceive the light, an even more pathetic group; those who see something (with the better eye) as we paradoxically phrase it, the practically or partially blind. But the matter does not end here. There remains the great group, excluded from the blind population by strict definition, but excluded, too, in large measure, from the ordinary avocations of life whereby bread is won, the "partly sighted." They are not at home in the world of those who have sight, or in that of those who are blind. They dwell in the borderland. They sit on the sidelines.

Let me turn for a moment to the blind. For our present purpose it is not necessary to argue about accuracy of statistical tables; it is safe to say that fully 100,000 men, women and children in this country are, within the strict definition, blind; one-fourth of this number need not have lost their sight—the causes of their misfortune are in large measure preventable. These 25,000 persons, by their blindness, deprive the country yearly of about eight millions of dollars' worth of productive labour. Now, the financial stability of our country is not disturbed by this loss of income; we can afford it; we cannot afford the stigma which the loss entails. Because we want this blot erased, we are here to help in the work of health education and of eye-sight protection; we are here to call on society for aid in devising measures and for means to carry them out in order that effective results shall merge into perfect victory. We are here, too, I take it, to cure those who are dull-sighted in this regard, so that with vision cleared they shall join in the struggle for ocular conservation and make it possible to give sweetness of disposition and ever-present cheerfulness, not to the blind (the good God attends to that) but to those who shall be saved from blindness.

The problems are manifold, and their solution of necessity varies in difficulty. Much result-begetting labour has been expended, and we are deeply in the debt of many physicians in their individual capacity and in their State and national organisations, and

in the debt, too, of many lay men and women, who also in individual capacity, organisation and in special field work have given a fine example of generous activity and effective service, which it is a joy to remember and a privilege to record.

The efforts to prevent blindness have been directed through many channels—legal, professional, institutional, social and industrial. They have often been described, and with most of them all of us are familiar. Time does not permit me now to do more than touch on one or two points. Twenty-five per cent. of the inmates of schools and asylums for the blind have lost their sight from that ocular disease usually named ophthalmia neonatorum, which is a conspicuous cause of preventable blindness. About 65 per cent. of the cases of ophthalmia neonatorum are due to a micro-organism of high pathogenicity, and this virulent type of the disease, it is estimated, is the cause of approximately 8 per cent. of the blindness in most of the regions of our country. If suitable measures are brought into action to check its ravages, the ocular mortality can be greatly reduced.

In general terms, the measures devised and in operation for the elimination of this preventable cause of blindness are education, compulsory notification, the punishment by law of offenders against properly constructed legal regulations, and compulsory prophylaxis.

EDUCATION.

In any programme for the prevention of blindness, education and its collaborator "publicity" properly receive large attention. Education intimately concerns the midwife and other persons who have charge of a new-born child, and it should be a prerequisite for the registration of midwives that they should give satisfactory evidence of a proficiency in the knowledge of the dangers and prevention of ophthalmia neonatorum. It is directly related to the duties of teachers of ophthalmology, obstetrics, bacteriology, sanitary science and hygiene, who should so instruct their students in this important subject that they may acquire not only the necessary information, but also a decent respect for their future responsibilities in this regard. But even more important are the education which should be received by the mother who expects to bring a child into the world, by those who constitute her family, by her neighbours—and, in short, by the society to which she belongs, and the methods by which this education shall be imparted. To one method I shall refer.

At stated intervals, in communities in which numerous foreigners and negroes of the poorer class are gathered together, from whom many of the most virulent types of this disease are recruited (a), meetings are organised, and the dangers of the disease are detailed and the methods of overcoming them are described, not by a physician, a social worker, or a visiting nurse, whose advice even when tactfully offered is often resented or regarded with suspicion, but by one of their own number, whose words receive respectful attention, and who has acquired influence in the community. His lecture or talk has been prepared for him in the simplest language, and is read or recited by him at the meeting described, always in the language spoken by the majority of his audience, and is illustrated with suitable lantern slides. In these circumstances mothers soon realise what they have a right to demand in the way of attention when their children are born; what they shall insist shall be

(a) Children of English-speaking parentage are by no means immune; for example, among 116 cases of ophthalmia neonatorum treated in the Gardner ward of the Massachusetts Charitable Eye and Ear Infirmary, according to some published statistics, it was found that 73 had come from English-speaking parentage and 63 from homes that were considered to be good. The scheme of instruction outlined above does not of course apply in circumstances like these.

done, and insistently done, if the eyes of the newborn baby show signs of inflammation; and what penalties may be imposed and must be paid if those in attendance disregard the danger with which the mother is now familiar.

I do not deprecate the excellent results which have followed campaigns of publicity, illustrated lectures, exhibits, newspaper articles, and the distribution of pamphlets of instruction, but I have potent reasons for believing that knowledge thus filtered into the homes of those who are likely to be affected receives an amount of attention far exceeding that which is given to the more usual courses of instruction to which I have referred, and many others who have followed this plan can give like testimony. Had I time I would read one of these lectures, prepared for just such meetings as I have described. For this method of conveying information we are indebted to Miss Henrietta B. Ely.

COMPULSORY PROPHYLAXIS AND THE FREE DISTRIBUTION OF A PROPHYLACTIC.

It is generally—and, I think, correctly—assumed that since the introduction more than thirty years ago of the Credé prophylactic method there has been a decrease in the number of cases of ophthalmia, at least in large institutions in which trained nurses and trained service are available. Most of us agree that in hospitals entirely devoted to obstetric service, or in hospitals in which large wards exist for this purpose, a modification of the original Credé method in the sense that the strength of the prophylactic is reduced from that originally recommended is of great value. While I do not doubt, as Mr. Van Cleve and others have pointed out, that the distribution of vials of a 1 per cent. solution of silver nitrate to registered physicians, nurses and midwives has proved to be an advertising device both effective and informing, I do doubt whether this is a remedy which it is safe to place in the hands of those who are improperly instructed, or who altogether lack instruction, but who none the less perform the duties of a midwife, and I further doubt whether a leaflet containing directions as to how these vials shall be used is of much service to any of these imperfectly educated persons, and I regret to say that imperfection in education in this respect is not alone a fault peculiar to midwives. I have seen so many severe silver catarrhs in my life, and have certainly seen at least half a dozen eyes badly injured by the reckless or improper use of silver nitrate, that I am inclined to agree with some of the contentions that are prevalent in England, particularly those of Mr. N. Bishop Harman, although I do not dispute the efficiency of the Credé method, and believe it to be essential in institution work and in the hands of those who are competent to use it.

Three years ago I endeavoured to ascertain, with the aid of the secretary of the committee on the prevention of blindness of the New York Association, whether any advantage or disadvantage had been derived from the compulsory distribution of a prophylactic agent against ophthalmia neonatorum. At that time the files of this office had no statistics to offer as to the advantage or disadvantage in these circumstances, and one was obliged to conclude, as the committee of the American Medical Association had pointed out, that the matter could be settled only by a consultation between committees of experienced physicians which exist in each State and the Departments of State public health.

I am fully aware that the distribution of a prophylactic among trained midwives and used by skillful physicians is capable of reducing the percentage of ophthalmia neonatorum, and it may even be, as Wootton has stated, that where the rigid supervision of midwives is enforced and where the

training of midwives by accomplished obstetricians takes place, a greater number of cases of ophthalmia occur in the practice of physicians than in the practice of midwives.

But this does not answer the objection which pertains to certain dangers which belong to the unrestricted distribution of the silver prophylactic, and if it is true that we are yet without the necessary information which should be on file, and which should decide whether the advantages derived from the compulsory distribution of a prophylactic agent against ophthalmia neonatorum outweigh certain disadvantages, we ought to have it as soon as possible. A consultation between committees of physicians and departments of health before referred to may be useful, but only too often represents a rather slow-working piece of machinery, and it would therefore seem to be imperative that one of the first duties of a national committee for the prevention of blindness should be to make, with the co-operation of the various State associations which are concerned in this vital business, an intensive study of this whole subject—a study which should be controlled from its central office and undertaken by field agents and others interested in this important matter. This becomes especially important because of the recent statement of one of the greatest of Continental authorities that sopher should be used in place of "the formerly employed Credé silver prophylactic."

In the absence of satisfying knowledge on this subject, and so far as my present personal experience is concerned, I believe that compulsory notification represents the most effective method at our command—a notification which should go at once to a legally qualified practitioner, or to a responsible board whose officers can quickly command the services of someone skilled in the treatment or the management of ocular disease. This usually secures promptness in treatment, and evidently, as Lucien Howe has said, should there be neglect in reporting, and should the strong hand of the law reach out to a person—no matter who he or she may be—who trifles with the vision of an infant, the effect is extremely salutary.

As is frequently the case, a district physician or registered midwife, recognising ophthalmia neonatorum in its earliest stages, sends the child to a competent eye dispensary, and the daily treatment is excellent, but it is not enough; it is the constant supervision of these eyes by trained persons which saves sight. Since all properly managed hospitals at the present time have as part of their equipment a social service, the difficulties of home treatment have been lessened, and the follow-up system has been productive of admirable results—as witness the value, for example, of this type of work in Boston and other cities.

And yet even the social worker and the follow-up system are not always able to control home treatment, or at least not able to make it as effective as the virulence of the inflammation of the baby's eyes may demand. In some cities there are hospitals with wards specially arranged, like the admirable Gardner ward of the Massachusetts General Hospital, for the treatment of these diseases, but many hospitals have no such wards. Not only have they no such wards, but many of them do not admit these cases.

In a collective investigation made by a member of my staff, Dr. T. B. Holloway, of forty-two hospitals in Pennsylvania, only two returned an unqualified statement that ophthalmia neonatorum patients would be accepted. Very properly, he concludes that hospitals receiving State aid should be compelled by law to provide suitable accommodation for the victims of ophthalmia neonatorum. More-

over, society, in the general sense of the term, which supports certain other hospitals not accepting State aid, should demand that they shall make similar provisions. The National Committee for the Prevention of Blindness should force this issue with all the influence it can command—not only because it represents a real work of humanity, but also, if you choose, from a commercial standpoint, because it would mean a reduction of the blind from this cause, and therefore a lessening of the economic loss to the commonwealth in which these hospitals exist.

In one State of this Union it has been computed that 100 of the young blind have lost their sight from ophthalmia neonatorum, and that these 100 young persons will eventually cost the State \$300,000 for education alone, while the economic loss to the commonwealth because of their lifelong dependence will be many times that sum. Three years ago, in the State of Pennsylvania, \$123,000 was appropriated by the commonwealth to four institutions or organisations for the blind, and approximately \$32,000 of this money was devoted to the welfare of those who were blind from ophthalmia neonatorum. Moreover, as Dr. Holloway in his admirable report on the subject points out, it costs the State of Pennsylvania approximately ten times as much to educate one blind child as it does to educate one seeing child. Perhaps if these figures, and similar estimates which could be readily gathered in the various States, were presented to the legislators, they would see fit to take into serious consideration such a law as I have ventured to suggest, especially if it were made plain that if a child with ophthalmia neonatorum in the earliest stages of its development can be transferred to a ward specially devoted to the treatment of this disease, except in rare circumstances, the inflammation can be brought into control and sight saved.

TRACHOMA AND GLAUCOMA.

Ophthalmia neonatorum and its ravages are so conspicuous that they have received, I will not say undue attention, for too much attention cannot be paid to this subject, but an attention which has overshadowed the importance of many of the other preventable causes of blindness. There is some danger that people outside of the medical profession and of the organisations devoted to visual conservation shall come to regard the prevention of blindness and the prevention of ophthalmia neonatorum as synonymous terms, and unwittingly fail to realise the scope and possibilities of the National Committee for the Prevention of Blindness. The same, in a certain sense, as Dr. Alger has pointed out, is true of trachoma, and important as the subject is from the standpoint of control of immigration, as well as from the standpoint of the elaboration of facilities for the management of this disease, now happily increasing on all sides, I shall not make further reference to it. Neither shall I attempt to discuss toxic blindness and its prevention, or the problems which surround certain infections, dyscrasias and constitutional diseases in their relation to the degradation of vision, or industrial blindness.

I wonder if it is generally realised how large a percentage of blind persons owe their loss of sight to the disease glaucoma. This disease shall serve as a sample of some of the work which it would seem to me pertains to such an association as this is and proposes to be. If a study is made of the cases of blindness in hospitals, it will be found that the percentage of blindness from glaucoma often exceeds that from any other cause; such an investigation was undertaken by the Massachusetts Commission for the Blind in 1910. To prevent this disease—or, rather, to check it after it has been discovered—

Mr. Greene suggests eugenic education, inasmuch as it is sometimes hereditary, the wise distribution of public clinics, and the careful record of the social worker's desk of patients who have come for the relief of glaucoma, so that they shall come under the influence of the follow-up system. All these suggestions are good, but a great difficulty is that patients with the non-painful, so-called chronic types of glaucoma often report too late. They do not realise what has been slowly taking place, and come only when vision is so far degraded that they are helpless. We educate, or try to educate, households in the dangers and symptoms of ophthalmias. Why not educate them in the early symptoms of glaucoma? I called to see a woman blind, or practically blind, from this disease not long ago, and while evolving the history—the long, pathetic history—I was struck with an expression of one of the children in the family, who remarked, "We used to wonder when mother took us to the movies why she always saw coloured rings around the lights." If only "mother" had known what those coloured rings meant there would be one less blind woman in the city from which I come.

Now, the social worker who makes, to use Mr. Greene's expression, a calendar of glaucoma patients in any hospital, and properly follows them up, will do much, for it is through this channel that the education most readily passes to the races among which this disease is most prevalent, and who are the best customers of the eye clinics. Furthermore, an important function of social service is concerned with the recognition of symptoms in those who sadly need attention, but who have never presented themselves for examination—not only in the house which is visited, but also in the neighbour's house—and quickly the knowledge of the symptoms of any disease which demands prompt treatment filters through a crowded street. Such a disease is glaucoma, with its long prodromal period, just the period during which the disease can be stopped before it has produced changes which are practically irremediable. I take this affection as an example. To many other ocular conditions the same plan of prevention applies. Therefore, it would seem that a national committee for the prevention of blindness should control a social service as part of its equipment, whose workers should specialise in ocular diseases, and who should in this regard assist in the extension of this work of the hospital physician into the life and home of the patient, and who would be attached to eye clinics and dispensaries which cannot afford the important help which comes from trained service of this character. The foundation of such a social service, controlled and supported by the National Committee for the Prevention of Blindness, would be welcomed by the social service organisations of this and other cities; it would possess both graduate and postgraduate possibilities, and would represent another arm of the great service which is dedicated to the work of saving sight. Time does not permit me to elaborate the plan and its effectiveness. I am sure society would realise the advantages which would spring from it, and, I trust, would support it.

WORK OF A NATIONAL COMMITTEE.

The work of a national committee for the prevention of blindness should not be concerned alone with the prevention of blindness, in the strict sense of that term. It ought to be concerned with, and surely is much interested in, the elimination of the evils which spoil eye efficiency. I am thinking about Elsa and the fading light, and I am thinking, too, of the kind of light that ought to exist in homes, in schools, in factories and in stores. To be sure, a great deal has been done along these lines, and is part of the committee's work. Think how much

has been accomplished since the almost universal examination of school-children's eyes has been made practically obligatory, and the problems of proper lighting have been carefully studied. Think how much good has been done by the Council on Health and Public Instruction of the American Medical Association in its publication of the "Conservation of Vision" series, under the stimulating influence of the capable chairman of the Committee on the Conservation of Vision, Dr. Allport. I venture to suggest that a national committee such as this is should have a sub-committee concerned entirely with the important question of illumination.

Doubtless every ophthalmologist can testify that scarcely a month goes by during which he is not consulted by some school or college or public institution as to the best type of illumination. Men in charge of these institutions want to know authoritatively about what Mr. Ferree calls the efficiency of the eye under different systems of illumination. We are all aware that the rays emitted by artificial lights, when studied with a spectrum, show a remarkable variety, and the potent remarks of Mr. Parsons on this subject may be emphasised—to wit, that too often the aim of inventors has been to attain a maximum efficiency, that is, a maximum illumination at a minimum cost, and comparatively scant attention has been paid to physiologic efficiency, and too little attention to the quality, that is, the wave lengths of the rays emitted by artificial sources of illumination. Would it not be a good thing if there was a department of the National Committee for the Prevention of Blindness to which application could be made for the latest information in regard to illumination? You may say that there are always illuminating engineers at the disposal of those who are interested in building operations, and, of course, such a department as I speak of would have to be in consultation with illuminating engineers and would need them on its staff. You know that doctors constantly appeal to the *Journal of the American Medical Association* for information on any given topic, medical or surgical, and know how admirable the replies are. Would it not be perfectly possible to have an information department on illumination and its relation to visual efficiency and the conservation of the eye, a department to which the inquirer could turn for the latest practical scientific information on this subject? I do not question that it would be supported handsomely if it were known that it had been established, and you would not have far to go for the chairman of that information bureau. You have him right here heading the list of your board of directors. The work of such a bureau would be interesting and effective.

According to Mr. Van Cleve, the most important part of this national committee's work at the present time is carrying on educational propaganda, furnishing material for workers in the field and inspiring such workers to service, and he believes that in these particulars its obligations are being met. He is fully alive, however, to the importance of creating through this national committee an agency for devising means to protect, care for and conserve vision. Indeed, it would seem to me, and I have no doubt seems to all of those who are concerned with the management of this organisation, that conservation of vision in the widest acceptance of the term should be a function of paramount importance in the administration of its affairs. It is impossible in the time at my disposal to do more than make reference to the problem, for example, which surrounds the education of those who are highly myopic, the necessity of classifying them according to the degree of their visual defect, and of arranging their work accordingly. This has been the subject of much study

on the part, for example, of Mr. N. Bishop Harman in London, where, as you know, there are schools—or, if not schools, departments in schools—where these high myopes, properly graded, are instructed with full consideration of their visual handicap. The same is true in the city of Berlin.

SCHOOLS FOR THE BLIND AND PARTLY SIGHTED.

But it must be evident that there are many children who, in general terms, are classified as "partially blind" and "partially sighted," and they constitute an essentially different group from the myopes to whom I have made reference. As Mr. Burritt puts it, from the point of view of the educator of seeing children, they are "partially blind"; from that of the educator of blind children, they are "partly sighted." They represent the class of which I spoke earlier in this paper, who, in general terms are not blind enough to be in a school for the blind, but who are too blind to keep pace with those who are in schools for the sighted. They are visually handicapped; they sit on the sidelines and cannot play the game.

It is not my province, nor is the time an opportune one, to discuss the co-education of blind and sighted pupils, or whether Mr. Harman's suggestion that all partially sighted children shall be excluded from schools for the blind shall be followed, or whether arrangements should be made in these schools for the blind to take care of those who have some sight. But it is interesting to know that there exist in some form in connection with the public schools of twelve States in the United States classes for the visually handicapped, and in most of these public schools there is a provision for the co-education of the blind and sighted. But more important, it seems to me, are those classes which have been instituted in Boston, in Cleveland, in Toledo, and in Cincinnati for the partly sighted children, even if the educator of seeing children looks on them as partially blind. Certainly provision should be made, as Mr. Burritt and Dr. Halloway point out, for the instruction of these children in connection with the schools of the children who have normal sight, because these visually handicapped persons must make their way through life not as blind, but as sighted people, and their associations should therefore be with those who see, and not with those who are blind.

It is a matter of great satisfaction to read the report of Mr. Irwin, who has charge of the special classes in the Cleveland public schools, sent within the last few days to our institution at Overbrook, that there are now four centres in the Cleveland public schools for totally blind children, and four for those who are partially blind—that is, partly sighted. The importance of having a number of centres must be manifest to everybody, as it solves at once the difficulties of transportation. Much is being done for these borderland dwellers, but much more can be accomplished, and therefore a national committee for the prevention of blindness and the conservation of vision should do all in its power to improve facilities of education in this regard, and should concern itself not only with the conservation of vision, but also with the utilisation of such vision as these handicapped children possess. In each community, through society, proper representations should be made to the various boards of education, so that they shall take up this matter, even as it has been most successfully taken up by some of the schools to which reference has been made.

It must be evident how great a work a committee such as this is and proposes to be can accomplish in this respect. As has often been pointed out, the principles underlying the management of partly sighted individuals depends in largest measure on a reasonably exact classification of the material

which would come under the observation of a national committee which concerned itself with this problem. We know that children with full sight in elementary schools ought not to be lumped together in their courses of instruction, and it has been well said by Harman that "the teaching of all children should be a retail and individual proceeding, not the wholesale, stock-pattern sort of thing that takes place in our elementary schools," and yet it is difficult to get away from this faulty *technique* because of the large number of children who apply for education. With the partially sighted the problem is not so difficult, the material being less great, and the classification could be more readily accomplished. Just here I am tempted to exploit one of my pet theories—namely, that in schools for the blind and schools where the partially sighted are educated, much help could be gained by a sensible application of the principles of modern psychologic research. I am sure this is true in schools for the blind, and I know that Mr. Burritt, of the Overbrook school, agrees with me. I have not time to tell you how I think it would work out, but I cannot help expressing the hope, if not the belief, that an investigation of this character among the partially sighted would help in the classification in accordance with the need of the case of each child, and I would like to see a trained psychologist on the staff of the national committee.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

CERTIFICATES OF DEATH FOR SOCIETIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Could you give me any information as to the requirements of benefit and other kindred societies with regard to above. I have frequently been deprived of my fees by some lay hospital official interposing and stating that my medical certificate of death will not do, but that one must be got from the registrar of the district. Practically this, if correct, repeals our right to give death certificates at all.

I am, Sir, yours truly,

T. L.

[We do not think that burial clubs and other such societies have any uniform rule as to the evidence of death they require. Some obtain a certificate of death from the registrar; others are satisfied with a certificate from the medical attendant.—ED. M.P. and C.]

TRANSACTIONS OF SOCIETIES.

THE HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, FEBRUARY 24TH.

The President, DR. EDMUND CAUTLEY, in the Chair.

THE TREATMENT OF GUNSHOT WOUNDS.

SIR BERKELEY MOYNIHAN opened a discussion on the above subject before a large meeting of members. His paper will be found on page 211 of our present issue. In the discussion that followed,

The PRESIDENT said that from the physician's point of view it had occurred to him that the use of tincture of iodine for antiseptic purposes was a fetish, and that any small benefit it yielded was due to the spirit it contained. With regard to the value

of carbolic acid, and of hyperchlorite solution, physicians had for many years used liquor sodæ chlorinatæ for cases of infective and so-called diphtheritic sore throats, and regarded it as of value. Possibly the benefit was analogous to that obtained from the hyperchlorite solutions, indicating that surgeons were now beginning to appreciate the value of drugs.

Another point worthy of discussion concerned the value of Sir Almroth Wright's theories with regard to the bactericidal power of serum. It seemed to him, as an onlooker, that there was no proof that the serum exuded under Wright's method was bactericidal. Its main value seemed to consist in the drainage set up, the production of a *vis à tergo*, which washed the organisms away.

With regard to the value of vaccines, he, like Sir Berkeley Moynihan, was sceptical, and considered that they were on their trial in regard to wound infections. He agreed, however, as to the value of vaccines in such diseases as enteric fever and paratyphoid fever. It still remained to be proved, however, whether it was of value when a patient was already suffering from a poison produced by organisms. There was a great tendency among surgeons, and to a less extent among physicians, to regard *post hoc* as *propter hoc*.

Mr. D'ARCY POWER, who followed, thought that the time had come for considering the after-effects of wounds which had received more or less successful treatment since the war began.

First was the question of re-opening wounds already healed, as where nerve-endings were involved in scars—characteristically in painful stumps; the secondary suture of nerves; unsightly scars, and re-fashioning of stumps. Often the immediate result of these operations had been to start a further course of suppuration, apparently because the pyogenic micro-organisms had been lying inertly in the healed wound. He was therefore inclined to defer secondary operations as long as possible. He also desired to know the experience of others about the course taken by dense infiltrating scars, the result of prolonged suppuration in extensive laceration of the soft tissues. His own opinion was that graduated movements made by the patient, and massage, made the tissue much more supple and amenable to treatment, making excision of the scar undesirable, at least, during the earlier periods. He felt sure that the immobilisation treatment of fractures and suppurating joints was carried to unnecessary lengths, and that when pain had ceased and the patient felt security on the limb massage and less splinting might be done. Stiff joints were best treated by bending under a general anæsthetic, but this was undesirable in the case of septic joints; in their case the septic inflammation should be allowed to subside for many weeks.

Turning to the medical side, those in general practice would have to bear in mind that numbers of their male patients had suffered from jaundice and would consequently be liable to inflammation of the gall-bladder and from gall-stones.

Mr. W. H. CLAYTON-GREENE said he had learned a good deal from Sir Berkeley Moynihan's able address. He, the speaker, had always a liking for antiseptics in surgery, and he thought their use should be encouraged. The one Sir Berkeley mentioned was an old one under a new name. Years ago, Mr. Edmund Owen, when he washed his hands before operating, used bleaching powder to sterilise them. But it must be remembered that all antiseptics were poisons, and some people showed a great intolerance for certain drugs. When the surgeon found that a wound was not doing well

under a certain treatment he naturally changed it; and he, the speaker, was much interested in what Sir Anthony Bowlby said in his Bradshaw lecture when emphasising the value of change in the treatment of wounds, and a variation in the antiseptic employed.

With regard to vaccines, the difficulty was that in carrying out Sir Almoth Wright's method one had no controls. In a given case vaccines were employed, and the patient got well; but the surgeon probably said the recovery was due to the good drainage. There were no controls, and without them he feared that vaccination, whatever its merits, would never receive its due recognition. He recently had two cases of streptococcal infection which recovered comparatively quickly after the use of vaccines; he did not think either of them would have recovered otherwise. But polyvalent vaccines should not be employed, only autogenous.

With regard to gunshot wounds, recent cases he had had very little experience of. He thought there should be very adequate drainage of the wound, and any foreign body in it should be removed at the earliest possible moment. When immediate amputation was practised for virulent infection and for gas gangrene, he asked whether the general opinion as to amputation by circular incision without flap formation was favourable or otherwise. The cases seen over here after that amputation had been practised were anything but encouraging.

He was chiefly concerned with the cases at a later stage as they came to the hospitals in England. By that time they were usually suppurating profusely. Some contained foreign bodies still. In many the agent of suppuration was the streptococcus, an organism which resisted the saline treatment. He asked whether it was advisable to make use of the new antiseptic in chronic infective cases, some weeks or months after the infliction of the wound. He had found the application of antiseptics to these chronic wounds was infinitely superior to the use of saline solution. An important problem was that in which the patient returned with a comparatively small wound discharging pus, and with a foreign body at the bottom of it. What was the proper treatment for such a septic sinus? Some of the cases were very obstinate. The danger in interfering with them was that of opening up fresh avenues of infection. Exploration should be deferred until the streptococcus had been got rid of. This he thought could be brought about in two ways, by prophylactic vaccines, and by Bier's method of cupping.

Concerning amputations, he believed that at the beginning of the war there was a fashion to amputate in nearly every case, by circular flaps or by no flaps at all. Then, later, surgeons were warned that they were amputating too readily, and that greater efforts should be made to preserve the affected limb. It was necessary to consider whether either of these methods was extreme. He thought that in the last few months there had been too great a tendency to try, at all costs, to save limbs, often at the risk of the loss of life of the patient. Some of the cases which had been sent across to him had been wasted and exhausted, and were evidently agonised with suffering, and begging to have the limb taken off. He had seen a limb arrive twisted and distorted, with a fixed joint, and riddled with tubes; and he had asked himself how a surgeon could be expected to save such a limb and make it good again. Even if it could be done, what months of real suffering the patient would have to undergo in the meanwhile. He wished to ask the surgeon to consider whether his desire for conservatism did not somewhat override his sympathy for the patient's sufferings.

Mr. DONALD ARMOUR welcomed Sir Berkeley Moynihan's iconoclastic method of dealing with the question of the use of tincture of iodine for wounds; it was a fetish which would probably now be demolished. Applied at the eleventh hour, he did not see how iodine could be expected to sterilise the skin. A very important point indeed was the need for free drainage of these wounds. In the South of England he had received cases from the firing line fairly early in which there was a lamentable lack of free drainage, possibly through lack of time to attend to the rush of cases. He regarded efficient drainage as a *sine qua non* in these cases. He had been much encouraged by the results following the use of magnesium sulphate and glycerine in these cases. He had done a fair number of secondary operations in common with nerve trouble, but the ill-effects in reopening wounds were associated specially with bone, in connection with which there was a real danger of a re-awakening of an old suppuration. Some weeks should be allowed to supervene before making any such attempt.

Mr. ALEXANDER FLEMING, speaking from the bacteriologist's standpoint, said that when he went out to France he found the clinical appearance of the wounds totally different from anything he had seen in civil practice, and that bacteriologically the difference was just as marked. The wounds in general resembled the foul-smelling appendix abscesses of civil life. The infection is primarily faecal, and the microbes in the early stages are those normally found in the intestines of men and animals—namely, *B. aerogenes capsulatus*, streptococcus, *B. proteus*, *B. coli*, and a number of spore-bearing putrefactive anaerobic bacilli (to which latter the foul smell is due), all of which are found in faeces.

In order to trace the source of infection of these wounds, cultures were made from portions of the soldiers' clothing, carefully selecting parts remote from the wound in order to avoid contamination from the wound discharge. These were incubated aerobically and anaerobically, and showed out of twelve samples 10 containing *B. anaerogenes capsulatus*, 5 containing streptococcus, 4 containing *B. tetani*, and 2 containing staphylococcus albus. The examinations were carried out in November, 1914, when there was much tetanus among the wounded. These experiments evidently showed that the soldiers' clothing was the source of the wound infection. The evolution of wound infection can be divided into three stages—first, a gross infection with anaerobic spore-bearing bacilli producing a foul-smelling sanious discharge produced by the action of the bacilli on the blood-clot in the wounds; secondly, the anaerobic bacilli disappear and the discharge becomes more purulent, but not as yet like the so-called "laudable pus." Then follows the third stage, consisting of an infection with pyogenic cocci. He considered the pyogenic infection to be the most important part of the sepsis.

In support of this opinion, Mr. Fleming had made the following experiment. He planted human faeces on blood-clot and incubated it anaerobically for 24 hours. A loopfull of this culture was transferred to a second tube of blood-clot and incubated like the first, and so on for ten days, in this way reproducing to some extent the wound infection. He found that the early cultures, in addition to streptococcus, contained many *B. aerog. caps.*, *B. coli* and putrefactive organisms, and that these got gradually less until after ten days all had almost entirely disappeared, except the streptococcus and some Gram-positive bacilli called "Wisp Bacilli" similar to those found in wounds, and so the tenth sub-culture had practically the same flora as an infected wound ten days old.

While wounds may become serious in the early stages from infection with tetanus, gas gangrene, and septicaemia, the streptococcal infection of the later stage is by far the more serious one with which we have to deal. All the septicaemias are due to this microbe. He described two distinct types infecting these wounds (1) the *Strept. faecalis*, relatively non-virulent, (2) *Strept. pyogenes*. A third one he found in about one-third of the cases, an anaerobic streptococcus, which had caused a rapidly fatal septicaemia in the patient from whose blood it had been isolated in pure culture.

He had made observations on the use of pure carbolic acid and iodine solution in alcohol for the primary sterilisation of wounds, and considered that the results were no better than had the applications not been used at all. The later infections of war wounds he considered not essentially different from those seen in civil practice; in both the streptococcus and staphylococcus play the most important part, the former being the more potent factor of the two.

As regards vaccines, he said that since 1903 all forms of sepsis had been treated at St. Mary's Hospital with vaccines, and in a very large number of the cases the benefit seen had been obviously due to the vaccines. They increased the anti-bacterial substances, and he thought that inoculation with small doses of streptococcus vaccine, or of "anti-sepsis" vaccine, which is a mixture of streptococcus and staphylococcus, would be beneficial in the later stages of these wounds; and that two or three inoculations preceding a secondary operation might prevent the recrudescence of the sepsis.

Dr. HARRISON ORTON demonstrated a small sterilisable screen and surface marker for locating foreign bodies in wounds, which can be used in the operating theatre.

Mr. DUNCAN FITZWILLIAMS said he had not seen cases in which sepsis could be prevented in wounds arising in this war. In his work at Malta, he saw cases at least seven days after the infliction of the wound, and the proximity to the case at once convinced one as to its condition. The first set of wounded cases came from the Gallipoli landing; there were 800 of them, and they had been brought in an ordinary ship; 18 or 20 died on their way. The others still had their field dressings on when they arrived. There were only three doctors on board. These conditions, however, improved later, and the hospital boats did an enormous work, as Mr. Edmunds would be able to say.

He wished to emphasise Sir Berkeley Moynihan's point that wounds in the limb should have, as a necessary treatment the immobilisation of the limb. There was then no lymph flow, and the circulation was reduced.

He emphasised the necessity of drainage of wounds. It was impossible for a vaccine, for instance, to do much when a wound was full of pockets of pus.

One's views about antiseptics had now to be scrapped. At Malta, the hypotonic salt solution method was used; the water of the Mediterranean was of about the right strength of salinity. Wounds did much better after that method. The application of antiseptics increased the rate of healing.

With regard to amputations, he remembered three or four patients whom he lost because he did not amputate straight away. He had learned his lesson. He felt sure it was wrong to do without flaps in amputating. If it were a case of gas gangrene the other measure would not save the patient; and if it were not, there was no need to do such a thing. Contrary to the teaching of some books, he would not undercut a single piece of skin in these cases; ordinary retraction would do everything as long as the muscles were cut right.

In reference to exposure of wounds to the air, the majority of those so exposed did well, but in hot countries the fly pest had to be considered; he saw several cases which were fly-blown.

X-rays he considered to be of no value in these cases, except as a surgical instrument for the purposes of locating bullets and other foreign bodies, and to ascertain the interior position of affairs.

Mr. EDMUNDS said he had the opportunity, at an early stage of seeing the cases which came from the Anzac Beach. They were got into an efficient operating theatre within 24 hours. For them a strong mixture on strong cyanide gauze was used. But in later stages of the war, when frequently a bullet passed through the bodies of several dead Turks before entering the patient, infection became a different matter. He fully agreed with what Sir Berkeley Moynihan said about the two antiseptics which his friend Dr. Dakin introduced, but their application required care in all details. It was of no use to put the hyperchlorite solution on only half a wound. After treating a wound with this, in a short time the discharge altered in character: instead of being creamy pus, it became a viscid pus; and if this occurred it was an indication that the material was being properly used; otherwise the recesses had not been efficiently reached. If one could not arrange the gauze in the wound, the latter should be opened freely. The replenishing could be done by any orderly in two minutes. He was as enthusiastic as Sir Berkeley Moynihan in regard to the value of Chloramine. He had kept his supply for a difficult class of mouth cases: there were some cases shot through the jaw, resulting in the palate being blown away. By putting the packing in the wound and keeping it moist with Chloramine, and washing out the mouth at frequent intervals, there was a healing such as he had never seen before. At Plymouth he removed a generous half of the tongue because of malignant growth, and sewed up the mucous membrane, and ten days later he took out the stitches, and during the whole of that time there had been no fetor in the breath. Chloramine was one of the most valuable additions to the surgeon's kit bag, and he hoped it would soon be put on the market; it was in a crystalline powder, and lasted for a long time. It could be used on mucous membrane, and the bladder could be washed out with it.

Sir BERKELEY MOYNIHAN, in reply, said he would like to put in a good word for the circular amputation. Those who saw cases in which the two methods had been carried out side by side would agree that the only thing to do was circular amputation. If even one stitch was put in, gas gangrene seemed to come on. He agreed with what had been said as to the lingering character of infections in wounds which had been healed; he had seen a patient die of tetanus after passive movement of the shoulder joint had been carried out; and the reopening of a healed wound seemed to revive infections which had become latent. Professor Layton was now working on it, and Mr. Bond, of Leicester, had dealt with the subject.

MAJOR L. COTTERILL, R.A.M.C., has been appointed surgeon on the personal staff in India of Lord Chelmsford, the Viceroy-Designate.

FAKENHAM (Norfolk) jumble sale in aid of the British Farmers' Red Cross Fund made over £4,058, which is a record for England.

SINCE the outbreak of the war nearly 7,000 free treatments have been given at Buxton to invalided officers and men.

ROYAL ACADEMY OF MEDICINE IN
IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, JANUARY 21ST, 1916.

The President E. J. McWEENEY, M.D., F.R.C.P.I.,
in the Chair.

CASE OF FOOD-POISONING DUE TO BACILLUS
SUIPESTIFER.

THE PRESIDENT referred to the case which he had already described in November last as one of food-poisoning due to paratyphosus B. His subsequent study of the causal organism showed that it was really a *suipestifer*, and capable of being distinguished from paratyphosus by both agglutination and absorption tests, diagrams of which he demonstrated.

Professor METTAM asked whether this micro-organism had been tested against pig's serum. He said that *B. suipestifer* was not uncommonly found in swine fever, though the primary cause of the disease was an ultra-microscopic parasite.

The PRESIDENT stated that only highly potential antisera could be used. He had not, as yet, tried the effect of pig's serum on the micro-organism, but would do so on the first available opportunity.

EXTENSIVE HÆMORRHAGIC INFARCTION OF SMALL
INTESTINE.

The PRESIDENT also showed the above case. The patient, A. S., æt. 60, a very obese elderly woman, with a small umbilical hernia, was admitted to the Mater Misericordiæ Hospital on January 12th. Her previous history was good. At 11.20 a.m. on the day of admission she was seized with violent epigastric pain; at 2.30 p.m. she took some whisky, which made her worse. She had had a motion earlier in the day, and an enema produced a copious action of the bowels. She vomited once only. There was nothing to point to intestinal obstruction. Her pulse and temperature were normal on admission. The urine contained some albumin. About ten hours after admission she became collapsed, and died quite unexpectedly. At the autopsy the small intestine was found in a state of complete hæmorrhagic infarction from about the middle of the jejunum to a few feet above the ileo-cæcal valve. The corresponding mesentery was also much thickened and infiltrated with blood. The infarction began quite suddenly at a spot where there was a sort of groove across the bowel, as though it had been pressed upon (though not obstructed) by a band. No band was, however, found. The coils of intestine below this were very thick and rigid, almost black in hue and distended with liquid blood. Towards the lower end of the ileum the process gradually ceased and the coils were of normal appearance. Owing to the extreme acuteness of the process there was no peritonitis. Dissection of the affected mesentery revealed no abnormal condition of the arteries. The smaller veins were distended with soft black clot, but the question arose as to whether it could be regarded as *ante mortem*. There were no adhesions and there was no Meckel's diverticulum, nor was there anything in the nature of a volvulus. The cause of the intense engorgement, and the nature of the band which had undoubtedly pressed upon the bowel, remain unexplained.

Dr. J. T. WIGHAM said that extensive necrosis was sometimes met with in cases of malaria, but he had never seen a case like the one exhibited.

Dr. R. M. BRONTE said he had brought forward an almost similar case at the last meeting of the

Section, and had met with two other cases recently which varied only in the extent of the lesions, the cause being similarly obscure.

The PRESIDENT, in replying, said he regarded the condition as one of thrombosis, but as death had supervened so rapidly there had been no time for the clots to become adherent to the vessel walls, as in typical *ante mortem* clotting.

PROSTATIC CARCINOMA.

Dr. J. H. POLLOCK demonstrated specimens from a case of above, with metastases in the lumbar glands and liver. The patient, when admitted to the Richmond Hospital, had complete retention of the urine. Catheterisation was found impossible, and suprapubic puncture was performed. He died shortly after admission. At the *post-mortem* examination the liver was found to be studded with comparatively small carcinomatous nodules. The entire column of the lumbar glands, from the under surface of the liver to the brim of the pelvis, was one white hard mass, which caused substantial aortic compression. A similar large mass was found within the pelvis upon the left side. Upon cutting open the prostate it exhibited an atypical structure suggesting carcinoma. Histological sections from the primary growth and secondary deposits showed typical alveolar carcinoma.

The PRESIDENT said these cases seldom came to autopsy. He considered it unusual to find metastases in the liver, but common to find them in the lumbar glands.

Dr. R. M. BRONTE said he had performed autopsies upon two cases which showed no metastases in the liver.

MICROSCOPICAL SECTIONS OF AN ANGEIOMA.

Dr. J. H. POLLOCK also showed microscopical sections of an angioma which had been removed by operation. The tumour had been present since birth in the subcutaneous tissues of the inner side of the knee in a young male adult. During the twelve months preceding the operation the tumour had grown sufficiently quickly to attract the patient's notice and cause him some anxiety. It resembled a single varicose cluster. Microscopical sections showed numerous blood vascular spaces lined by several layers of low cubical cells. These cells in certain areas appeared to show complete differentiation into endothelial plates, but in the majority of cases the erythrocytes were directly enclosed by the less differentiated and presumably vegetative cells. These characters, combined with the clinical feature of active growth, would place this tumour in the category of true hæmangioma as opposed to hæmangiectasis—a mere dilatation of non-proliferating vessels. He said cases had been reported where such tumours exhibited malignancy, and in one instance metastases had been recorded.

The PRESIDENT said he considered the exhibit as a good specimen of hæmangeio-endothelioma, but missed the continuous lining of endothelium in some of the spaces.

Professor METTAM said he had met similar angiomatata in the liver of animals; these showed several layers of endothelium, and occasionally some of the blood-containing spaces had no endothelial lining.

Dr. POLLOCK, in replying, said he regarded the proliferation of the endothelium as an essential feature of the condition, though a single layer of cells might be found in some spaces.

BOTHRIOCEPHALUS LATUS.

Dr. T. T. O'FARRELL showed a specimen of the above. The patient from whom the specimen had been taken lived in the Co. Longford, on the banks of the River Shannon. The man had suffered for some time from vague symptoms of

"indigestion," but had no pronounced anæmia. He passed the first segments of tapeworm at the end of December, 1915. The usual anthelmintics had been given, and the whole worm was passed; he failed to find the head, but the smallest segments were presented for examination. The following facts were elicited from the patient:—(1) He had always resided in Ireland, except for three trips to England and two to Scotland, each of about five or six days' duration. On these occasions he did not partake of fish. (2) He had frequently eaten fish taken from the Shannon—namely, perch, pike, bream, roach, also eels, but no trout so far as he remembered; they had not been undercooked. (3) Several people partook of the same fish, but so far as he was aware did not suffer from tapeworm. He (Dr. O'Farrell) said this was the first specimen he had seen in Ireland, and in the limited references he had consulted he had not seen the presence of this parasite recorded in Ireland. The tapeworm he had frequently met with was the *T. saginata*.

The PRESIDENT said the tapeworms he had met with were mainly *T. saginata* and a few *T. solium*, but he had not met with the *bothriocephalus latus*.

Professor METTAM always regarded this parasite as practically unknown in this country. He was interested to hear the common finding of *T. saginata* in man, as he had never seen the *Cysticercus bovis* in animals brought to the Royal Veterinary College.

SPECIAL REPORTS.

ROYAL COMMISSION REPORT ON VENEREAL DISEASES.

The final report of the Royal Commission appointed in November, 1913, "to inquire into the prevalence of venereal diseases in the United Kingdom, their effects upon the health of the community, and the means by which those effects can be alleviated or prevented," has now been issued [Cd. 8, 189].

The *Times* gives the following *precis*:—

Among the general conclusions set forth are these:—

- (1) In distribution the incidence of syphilis is much higher in urban than in rural areas. The same is probably true of gonorrhœa, though statistical proof is not available to the same extent.
- (2) The available statistics afford no satisfactory evidence of the prevalence of venereal diseases, but in the large cities it is estimated that at least 10 per cent. of the population are affected by syphilis and a much higher proportion are affected by gonorrhœa.
- (3) Venereal diseases can be controlled and reduced within narrow limits by early and efficient treatment, but at present treatment is in most cases unduly deferred and adequate facilities for the best modern treatment do not exist.
- (4) To bring modern methods of treatment to bear on every infected person, Government action is essential.

The effect of the recommendations of the Commission may be summarised thus:—

- (1) Arrangements should be made for accurate statistical records of the prevalence of disease, including the confidential registration of causes of death.
- (2) Facilities for the diagnosis and free treatment of venereal disease should be organised by the larger local authorities (county councils and county borough councils), the Imperial Exchequer to contribute 75 per cent. of the cost.
- (3) No system of notification of venereal disease should be adopted for the present.
- (4) Advertisements of remedies for venereal diseases should be prohibited.
- (5) Legal protection should be given to medical men to enable them to make confidential communications with the object of preventing or delaying a marriage on the ground of venereal disease.
- (6) Infectious venereal disease should be made a

statutory incapacity for marriage; and the children of such a marriage should be relieved of the disabilities of illegitimacy.

- (7) More careful instruction in regard to moral conduct in sexual relations should be provided throughout all types and grades of education.

THE REPORT.

The report is signed by all the Commissioners—namely, Lord Sydenham (Chairman), Sir D. Brynmor Jones, Sir Kenelm Digby, Sir Almeric FitzRoy, Sir Malcolm Morris, F.R.C.S. Edin., Sir John Collie, M.D., Dr. Arthur Newsholme, Canon J. W. Horsley, the Rev. Dr. J. Scott Lidgett, Dr. F. W. Mott, Dr. Mary Scharlieb, Mr. James E. Lane, F.R.C.S. Eng., Mr. Philip Snowden, M.P., Mrs. Creighton, and Mrs. Elizabeth Burgwin. The signatures of Sir Kenelm Digby and Canon Horsley are subject to reservations.

The disadvantage of issuing the report "when all public activities are pre-occupied in fulfilling the manifold needs of the war" is recognised. But it has been published because "the conditions now existing and those which must follow on the conclusion of the war, imperatively require that action should be taken without delay. The report proceeds:—

"There is no reason to believe that the percentage of infection in the naval and military forces is now greater than in normal times; but there can be no doubt that the total of infected persons has increased. The military authorities are doing their utmost to provide treatment, but the civil population requires corresponding measures, and all experience shows that after a war an excessive incidence of disease is certain to occur, even in districts previously free. . . . We are therefore convinced that it will not suffice to establish treatment centres in places where sailors and soldiers are congregated, and that these will be needed in most of the larger and in some of the smaller towns. We realise the claims of economy at the present moment; but, for reasons we have given, we believe that all necessary expenditure will be recouped by the results which can be obtained."

PREVALENCE.

The Commissioners found that, except in the case of the Navy and Army, there are at present no means of arriving at an accurate estimate of the prevalence of venereal diseases. The tendency to concealment, by militating alike against the acquisition of full knowledge of the extent of their incidence and against the prompt treatment which is so necessary, render them peculiarly dangerous to public health. Moreover, it is only in comparatively recent years that their varied effects have begun to be recognised, while more in this direction still remains to be discovered. Partial attempts to obtain a local census of venereal diseases have been made in some countries; but the results are not such as to justify generalisations. A large number of examinations in institutions, and among special sections of the population, including *post mortem* tests, have been made in the United Kingdom, as in foreign countries, and generally show an unexpectedly large prevalence. The recorded death rate in this country per million for syphilis and the three consequential diseases, distributed among eight classified groups of the population shows the prevalence to be greatest in the unskilled labour class, and least amongst miners and agricultural labourers. But at present registration is defective, many deaths due to this cause escaping recognition. Sir William Osler considers that "of the killing diseases syphilis comes third of fourth." While unable to arrive at any positive figures, the Commissioners come to the startling conclusion that the number of persons who have been infected with syphilis acquired or congenital, cannot fall below 10 per cent. of the whole population in the large cities, and the percentage affected with gonorrhœa must greatly exceed this proportion.

ECONOMIC EFFECTS.

A striking section of the report shows that both the diseases named lead to an enormous annual loss of child life. It is estimated that from 30 to 50 per

cent. of sterility among women is due to gonorrhœa, and of registered still births probably at least half are due to syphilis. Of 1,100 children in the London County Council schools for the blind, at least 55.6 per cent. of the cases are attributable to venereal diseases in the parents. A large proportion of juvenile cases of imbecility, idiocy, deafness, and various forms of skin, bone, and other diseases result from congenital syphilis. It is shown that among adults the loss of working power from the earlier effects of the diseases is important, while in their later manifestations they are responsible for a vast amount of incapacity. In a considerable proportion of cases syphilis, at an average period of 10 to 15 years after infection, shows itself as general paralysis of the insane or locomotor ataxy.

Reference is made to the heavy cost of the public maintenance of persons thus afflicted, and the total economic loss is justly described as "enormous." The Commissioners are satisfied that a large proportion of the total expenditure can be saved, and will far more than counterbalance the cost of the measures they propose.

FREE TREATMENT.

By the terms of reference Lord Sydenham and his colleagues were precluded from considering the policy of the much controverted Contagious Diseases Acts of 1864 and 1866, which were repealed in 1886; but they place on record their view that no advantage would accrue from a return to the system. So far from this being the case, it is to be noted that the great improvement as regards these diseases in the fighting services has taken place since the repeal of the Acts. Except in the case of those services, the Commissioners find the existing facilities for treatment are "extremely deficient." They are of opinion that no adequate system of treatment will be organised unless responsibility for it is undertaken by the State. Measures should be taken to render the best modern treatment readily available for the whole community, by the use of special wards in the general hospitals, rather than by the establishment of separate institutions. In reference to the objections still persisting in the minds of some subscribers to general hospitals, the report expresses the hope that "when the facts elicited by our inquiry are made public, the view that morality can be encouraged by denying medical treatment to those who, by violating its laws, have become a public danger, will disappear."

Subject to the approval of the Local Government Board, the councils of counties and county boroughs should organise and carry into effect definite schemes for dealing with the diseases, and as a first step should approach the general hospitals in their areas with a view to making the necessary arrangements. Treatment at any institution should not be restricted to persons resident in a particular area; it should be free to all, and there should be no refusal to treat a patient who is unwilling to go to his own doctor. Special arrangements, such as evening clinics, should be made for the treatment of out-patients at hours convenient for the working classes. Subject to proper safeguards, local authorities should be empowered to supply salvarsan or its substitutes gratuitously to medical practitioners.

Extended facilities should be made available for diagnosis by laboratory methods, and be organised by the larger local authorities, the fullest use being made of the laboratory facilities at universities and hospitals. The Commissioners recommend that one-fourth of the public expenditure for these purposes should be met from local rates, and the remaining three-fourths should be provided by Imperial grants, distributed by the Local Government Board.

COMPULSORY DETENTION.

Generally speaking, the Commissioners have been slow to advocate compulsion in any form. For example, they report against any system of compulsory personal notification, believing that it would fail to secure the advantages claimed, and that better results may be obtained by the improved facilities for treatment they recommend, and by a policy of education regarding the serious nature of these

diseases. It is in respect to one limited form of compulsion that the only departures are made from the unanimity of this valuable report. Sir Keneim Digby and Canon Horsley attach reservations objecting to the proposed detention of Poor Law patients suffering from these diseases, and the former is not prepared to support the thorough medical examination of persons committed to prison recommended by his colleagues. It may be remarked that the principle of detention in Poor Law institutions in cases of diseases dangerous to the community was laid down in the Poor Law Act of 1867. While holding the case for the similar detention of prisoners to be a strong one, the report accepts the opinion that it would be more expedient to rely on the co-operation of Discharged Prisoners' Aid Associations and similar bodies in any general system of free treatment. It is suggested that when an infectious man is entitled to claim his discharge from the Army or Navy he should be encouraged in his own interest to continue under treatment.

THE MARRIAGE LAWS.

The unanimous proposal of the Divorce Commission that statutory recognition should be given to the principle that infectious venereal disease constitutes an incapacity for marriage and should be a ground for divorce is strongly endorsed. If under the existing law the effect of a decree of nullity is to render the children illegitimate, it should be provided that the disabilities attaching to such a condition should not follow. Another amendment of the law recommended is that a communication made *bona fide* by a medical practitioner to a parent, guardian, or other person directly interested in the welfare of a woman or man, and with the object of preventing or delaying a marriage with a person who is in an infectious condition, shall be privileged communication.

"A FRANKER ATTITUDE."

Measures are proposed to ensure that every medical student has adequate practical instruction in these diseases. Their treatment by unqualified persons is emphatically condemned as disastrous, and constituting one of the principal hindrances to eradication. The recommendation of the Select Committee on Patent Medicines that all advertisements of remedies for these diseases should be prohibited is endorsed. Approved societies which debar from sick benefits persons whose illness is due to misconduct, but freely admit those who are suffering from consequential diseases, which early treatment would have prevented, are urged to revise their practice.—

"There can be little doubt that a franker attitude towards these diseases would lead to less concealment, often involving recourse to quack remedies, which may retard cure or render it impossible, and would thus assist in checking one of the greatest evils that can inflict a community."

A section of the report is devoted to the important question of public education in these matters. More careful instruction should be provided in regard to moral conduct as bearing upon sexual relations throughout all types and grades of education. It should be based on moral principles and spiritual considerations, and not merely on the physical consequences of immoral conduct. The National Council for Combating Venereal Diseases should be recognised by Government as an authoritative body for the purpose of spreading knowledge and giving advice.

SUBSTITUTES FOR SALVARSAN.

As regards anti-syphilitic drugs, it is pointed out that mercury and arsenic proved their value in the past. Salvarsan (606) belongs to the arsenic group. It is a German product and substitutes have been prepared, the most important of which are Kharsivan and neo-Kharsivan and arsenobenzol-Billon, English and French products respectively. Reports of the use of these drugs are to hand and are very satisfactory. It is pointed out that syphilis can be cured if promptly treated by a doctor, and it is recommended that the public should be informed that the disease may be acquired by kissing and by using the same eating or drinking utensils or tobacco pipes

as a syphilitic person. The statistics of the social distribution of the disease appear to show that unskilled labourers head the list. Next comes "intermediate labour," and then the upper and middle classes. At the bottom of the list are miners and agricultural labourers.

The members of the Royal Commission have been invited to join the National Council for Combating Venereal diseases and the majority of them have accepted.

OBITUARY.

DR. JOSEPH PEARCE WILLS, M.D., M.R.C.S.,
BEXHILL.

Dr. J. P. WILLS died at a Bexhill Nursing Home on February 28th, after an operation. Dr. Wills was the doyen of the medical profession in Bexhill and held a very high reputation, not only as a general practitioner, but as a specialist in lung diseases and mental troubles. He received his medical education at St. Mary's Hospital, qualifying M.B., B.S., Durham in 1880, and M.R.C.S. in the same year. He took the M.D. degree in 1886. He had practised in Bexhill for over 30 years and had been closely identified with all its phases of growth and progress for many years. He was a member of the Bexhill Corporation and resigned his Aldermanship about six years ago. Dr. Wills was formerly M.O.H. of the Bexhill U.D.C., and medical officer to the Bexhill Convalescent Home. He was the author of an essay, "For the Erection of a Sanatorium for Tuberculosis," which was awarded honourable mention in 1902 by the King's Advisory Committee. Of late he had made many noteworthy speeches in connection with war and recruiting.

DR. T. BLASSON, M.R.C.S., L.S.A., BILLINGBOROUGH, LINCS.

THE death occurred at Billingborough on March 2nd, of Dr. Thomas Blasson, one of the best-known members of the medical profession in the district, and probably the oldest acting surgeon in the Southern part of Lincolnshire. His illness only extended over a few days, and he succumbed to an attack of pneumonia. He was educated at Guy's Hospital, between 1852-56, and became clinical clerk to Dr. (afterwards Sir) William Gull, and for about six months he acted as "dresser" for Mr. John Birkett—a famous surgeon in those days. He qualified M.R.C.S. in 1855, and L.S.A. in the following year, and then returned to Billingborough to assist his father in his profession, succeeding him in 1864. He was in practice for 60 years, and died in the house in which he was born.

For many years he was surgeon to Folkingham Gaol until it was closed by order of the Home Secretary. Since the passing of the Public Health Act in 1875, he acted as medical officer and public vaccinator for the district. He was surgeon to the Bourne and Sleaford Railway and the Post Office, and had been professionally connected with the Oddfellows and A.O.F. for upwards of 50 years. Deceased, who was 81, was an active practitioner up to within a few days of his death, always doing his round—sometimes over 20 miles—in an open trap.

MEDICAL NEWS IN BRIEF.

Prudential Assurance Company, Limited.

THE 67th Annual Report and accounts for the year 1915 have just been published. The rate of interest assumed for the purpose of the valuation was 3 per cent. The rate actually earned on the assurance funds exclusive of reversions was £3 16s. 9d. after the deduction of income tax, and for the previous year £4 os. 1d.

The results of the valuation shew that in the ordinary branch there is a surplus, including £263,724

brought forward from last year, of £1,519,331. In the industrial branch, life assurance fund on December 31st, 1915, £42,714,625, net liability, £41,671,600, the surplus, including £293,947 brought forward from last year, is £1,043,025; whilst the general branch shews a surplus, added to reserve for sickness claims, of £7,236.

The provisions relating to Industrial Assurance contained in the Courts (Emergency Powers) Act, 1914, have resulted in a severe strain upon the Company's resources which has reduced the surplus shown on the operations of the year, and whilst these provisions remain in force the strain must continue. In these circumstances the Directors have not felt justified in drawing upon the £300,000 set aside last year to meet contingent liabilities created by the Act, but have met the loss out of revenue and in addition have felt it necessary to increase the amount set aside by £50,000. The Courts (Emergency Powers) Act Reserve therefore stands as at December 31st, 1915, at £350,000.

An interesting feature of the report is the following letter from the Chancellor of the Exchequer to Mr. May, Secretary of the Company, dated August 4th, 1915. "I have to thank the Prudential Assurance Company on behalf of His Majesty's Government for the patriotic spirit they have shown in placing the whole of their American securities at the disposal of the Treasury at a fair and reasonable price. The transaction has been of considerable assistance in facilitating Exchange operations, and the greatest credit is due to the Company for its prompt action."

Research Defence Society—Dublin Branch.

THE annual meeting was held in Dublin on March 1st. The report stated that the Dublin Branch of the Research Defence Society has been in existence for seven years, and during that period the efforts of the Society had been successful in enabling the public to grasp the meaning and objects of medical research. During the year, the subscriptions had decreased, partly by reason of the war with its many claims, but for the most part because the members and the public considered that the battle for truth is already won, and thought, perhaps, that the Society no longer needs their support. The members ought to congratulate themselves on a great victory, the fruits of which were seen in the many thousands of soldiers saved from death by the results of medical research. There was still need, however, to keep the Society active.

Out of the funds of the Branch a sum of £20 had been contributed to the Parent Society and at the close of the financial year there was a balance to credit of £7 8s. 6d.

Dr. A. D. Waller, F.R.S., then gave an address on Fat Consumption in Time of War. He said that a dominant factor in the German economic situation was the amount of fat for food and for explosives. One hundred tons of fat would yield ten tons of glycerine which could be nitrated to yield twenty tons of nitro-glycerine. Germany had hitherto consumed fat at the rate of 106 grammes per head, i.e., in round numbers, 2½ million tons per annum. For industrial purposes Germany had used half million tons, of which 100,000 tons went to nitro-glycerine. Half had been grown at home; half had been imported. During the first year of war, Germany had required for food, at least half her previous allowance, i.e., at least 1½ million tons plus 350,000 tons for war explosives; she had not been able to produce this amount at home. She had succeeded in importing it from abroad, and in extracting it from occupied territory. He gave figures as to linseed oil, and dealt with the necessity of stopping the supply of fat to Germany.

Time-Gun and the Soldiers' Nerves.

THE firing of the Dundee time-gun is to be stopped during the war. This step has been decided upon because of a report that the firing of the gun had a very bad effect upon the nerves of a number of soldiers who were suffering from what might be termed "cannon shock."

Large Bequest to King Edward's Hospital Fund.

ISABELLA, Countess of Wilton, of Upper Grosvenor Street, W., left unsettled estate of the gross value of £290,488, of which £279,789 is net personality.

Amongst other legacies, Lady Wilton bequeathed £1,000 each to the Hospital for Epilepsy and Paralysis, Maida Vale, W., the Fever Hospital, Islington, the Taunton and Somerset Hospital, and the London Hospital. The residue of the estate, which apparently represents over £200,000, is left to the King Edward's Hospital Fund.

The London Hospital.

THE report presented at the quarterly meeting of the Governors of the London Hospital on March 1st, referred to the need of opening the wards presented by the Grocers' Company for the salvarsan treatment of specific disease, "which to-day is endangering the welfare and future of our people, and must be stopped." It said that it was not easy for the Governors to undertake that work, as last year, owing to the increase in prices, they had spent £14,000 more than they had received.

The increased cost of provisions accounted for nearly £10,000, while the prices of drugs had increased to an abnormal extent. The meat bill was nearly £3,000 up; milk nearly £2,000; fish and poultry, £700, and vegetables nearly £400.

Eyesight and Commissions.

IN reply to Mr. Duncan Millar, who asked what is the present standard of vision required in the case of applicants for commissions in the Army and the Reserve, and whether applicants who are below the standard required for active service are being accepted for home service, Mr. Tennant states:—The vision of applicants for commissions in the Army must not be below 6-24 without glasses and after correction with glasses it must be normal in the better eye and 6-12 in the other. For candidates for the Special Reserve of Officers the standard required is as just stated, except that vision without glasses in each eye must not be below 6-36. There is no special standard required for active service as distinct from home service.

Birmingham Children's Hospital.

A WARNING note as to a coming scarcity of medical men for hospital work was sounded at the annual meeting of the Birmingham Children's Hospital held on February 28th.

The Medical Committee reported that in view of the increasing demands of the army and the increase in the cost of drugs they were of opinion that the question of further limitation of work in the out-patient department would have seriously to be considered, and the number of out-patient operations reduced.

Mr. B. J. Ward (chairman of the Medical Committee) pointed out that it was likely the services of medical men to the hospital would have to be curtailed before long. Every medical man under 45 years of age was now being requested to accept a commission in the R.A.M.C., and to hold himself in readiness to be called upon. The War Office were forming a huge reserve of medical men for the push when it did take place. It was impossible to say when it would happen, but probably it would take place during the next two months. Then the medical men would be called to the colours, and the hospitals would be left to look after themselves. In the circumstances it would be wise of the committee to make arrangements to face the difficulty. To his mind it was almost certain to occur. The medical men were not likely to receive much notice; it might only be a few days.

Royal Gwent Hospital.

AT the annual meeting of the subscribers of the Royal Gwent Hospital on February 25th, Sir A. Garrod Thomas, D.L., who presided, submitted the directors' report which showed that the number of in-patients treated during 1915 was 1,403, while 8,114

out-patients received treatment during the year. The income amounted to £11,920 14s. 8d., and the expenditure £10,775 13s. The accumulated deficiency £3,669 18s. 8d., at December 31st, 1914, had been reduced by £1,145 1s. 8d., and the deficiency now stood at £2,524 17s. Workmen's contributions were the highest on record, and a house-to-house collection resulted in £521 3s. 10d. being paid over, while Queen Alexandra's "Rose Day" yielded £288 19s. 9d. Within the next few months it was expected that the new wing would be completed and the necessary equipment provided. This would provide an additional 18 beds, two more operating theatres, and an improved casualty department.

Dealing with the question of the honorary staff, he said things looked very gloomy. Their doctors had gone off with the colours, and they were now seven short. They also had a difficulty in securing house surgeons. They found it was impossible for them to compete with the khaki, cash, and kudos of the War Office.

The National University of Ireland.

THE Senate met on Wednesday, March 1st, 1916. The Senate directed that the Special Examination for the Degrees of M.B., B.Ch., B.A.O., to be held in June, 1916, shall be open only to candidates who, if qualified as a result of that examination, undertake to apply at once for commissions in the Indian Medical Service, the Royal Army Medical Corps, or the Naval Medical Service.

Heavy Infantile Mortality at Dundee.

THE annual report of the Dundee medical officer of health states that the number of infants who died in the first year of life in 1915 was 821, and the infant mortality rate for the year was 209 per 1,000 births. This is the highest figure recorded since 1893, when it was 217. It was entirely due to a serious outbreak of whooping cough and measles and an increase in the deaths from bronchitis and pneumonia, which always accompanied these diseases, especially in severe weather.

Bradford Eye and Ear Hospital.

THE annual meeting of the Royal Eye and Ear Hospital, Bradford, was held on February 25th, under the chairmanship of the Lord Mayor.

In the course of the annual report the committee of management stated that they were glad to report affiliation with the Bradford War Hospital, and that their offer to undertake eye and throat work had been accepted. During the year 1915 there were 7,702 new cases in the out-patient department, compared with 7,814 in 1914, and 1,045 old cases, compared with 1,597 in 1914. In 1915 the aggregate of days and occupied beds for in-patients was 12,779. There were 1,611 operations. The total expenditure for the year was £4,520 8s. 10d., and the receipts amounted to £3,937 13s. 3d. Notwithstanding the transfer of £1,904 from the Special Appeal Fund, there was still a debt of £4,765 on the hospital. The institution had been able to afford treatment to a considerable number of His Majesty's forces, as well as a large number of cases of minor accidents amongst munition workers. Numerous Belgian refugees had also been helped. Of considerable benefit to the working of the hospital had been the taking of the Christ Church vicarage as a home for the nursing staff.

Hospital Benefits by the War.

THE Bishop of St. Asaph presided at the annual meeting of the Royal Alexandra Hospital and Convalescent Home at Rhyl on February 26th.

The report stated that considerable demands had been made on the hospital by the military, and the increase in the receipts had enabled the committee to extinguish the building debt and to carry forward a substantial balance.

Central Midwives Board for Scotland.

THE Privy Council has intimated approval of the appointment of Mr. D. L. Eadie, 50, George Square, Edinburgh, as Secretary to the Central Midwives Board for Scotland. All communications thereanent should be sent Mr. Eadie at the above address.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

CLINICAL LECTURES, PAPERS, ETC., RECEIVED.

The following have come to hand, and are hereby acknowledged with thanks:—

GRENET, PROFESSOR M. H., Médecin des Hôpitaux, Paris. "Treatment of Acute Articular Rheumatism with Intravenous Injections of Colloidal Gold."

MACKENZIE, DAN, M.D., F.R.C.S. Edin., Surgeon to the Central London Throat and Ear Hospital. "Folk Cures by Constriction and Rings."

MOYNIHAN, SIR BERKELEY, F.R.C.S. Eng. and Irel., Professor of Clinical Surgery, Leeds University. "The Treatment of Gunshot Wounds."

NEWBOLT, G. P., F.R.C.S. Eng., Surgeon to the Royal Southern Hospital; Lecturer and Examiner in Clinical Surgery, Liverpool University. Clinical Lecture on "Cancer of the Breast."

NEWTON, RICH, C. M.D., Montclair, Jersey. "The Origin of Auscultation and Percussion in Laennec's Time."

PARKER, RUSHTON, M.B. Lond., F.R.C.S., Professor of Surgery in Liverpool University; Consulting Surgeon, Liverpool Royal Infirmary. "Fæcal Fistula of the Abdomen."

ROBERTSON, GEO. M., M.D., F.R.C.P., Physician-Superintendent, Royal Asylum, Edinburgh. "The Employment of Female Nurses in the Male Wards of Mental Hospitals."

ROLLESTON, J. D., M.D. Oxon., B.Ch., Medical Officer, Grove Hospital, Tooting, London. "The Blood Pressure in Typhoid Fever."

RUSSELL, WM., M.D. Edin., F.R.C.P., Professor of Clinical Medicine in Edinburgh University; Physician to the Royal Infirmary, Edinburgh. Clinical Lecture on "Two Cases of Malignant Disease of the Body of the Stomach."

THOMSON-WALKER, J. W., M.B., F.R.C.S. Eng., Surgeon to King George's Hospital, and to St. Peter's Hospital for Stone. "Hexamine as a Urinary Antiseptic."

WHITEFORD, C. HAMILTON, M.R.C.S. Eng., Surgeon to the South Devon and Cornwall Hospital. "Surgical Don'ts." Third series.

WILLIAMS, TOM A., M.B., C.M. Edin. "On the Traumatic Neurosis."

We have to apologise to our Irish readers for the inconvenience caused them last week by the delay in the delivery of our SUPPLEMENT. The delay occurred while the parcel was in the hands of the carrier, while the parcel was on its way to our office from the printers.

OMEN (Bath).—The sixteenth annual report of the Dundee Royal Victoria Hospital states that during 1915 the cancer wards had been practically full, and the deaths which had occurred in the hospital during 1915 presented a formidable number, which had not previously been attained. The incidence of cancer was strikingly in excess, and 20 of the patients had died from the disease.

SONA (Baldoek).—We note that 38 doctors on the Herts panel list have enlisted.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 8th.

ROYAL SOCIETY OF MEDICINE (1 Wimpole Street, W.).—Occasional Lecture: Dr. Leonard S. Dudgeon will deliver a lecture on "Personal Experiences on the Gallipoli Peninsula and Eastern Mediterranean while a Member of the War Office Committee for Epidemic Diseases and Sanitation," in the Robert Barnes Hall, at 5 p.m. Lantern illustrations. N.B.—Members of all Sections are invited.

ROYAL SOCIETY OF ARTS (John Street, Adelphi, W.C.).—4.30 p.m.: Paper. Mr. C. R. Darling: Optical Appliances in Warfare.

HUNTERIAN SOCIETY (1 Wimpole Street, W.).—8.30 p.m.: Council Meeting. 9 p.m.: Paper. Dr. Langdon Brown: A New Treatment of Diabetes. Discussion invited.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Hunterian Lectures. Professor J. E. R. McDonagh: Links in a Chain of Research on Syphilis.

FRIDAY, MARCH 10th.

ROYAL SOCIETY OF MEDICINE (1 Wimpole Street, W.).—Occasional Lecture: Dr. M. Weinberg (of the Pasteur Institute, Paris) will deliver a lecture on "Bacteriological and Experimental Researches on Gas Gangrene" (with Epidiascope demonstration, Cultures, etc.), in the Robert Barnes Hall, at 5 p.m. N.B.—Members of all Sections are invited.

Vacancies.

Bethlem Royal Hospital, London, S.E.—Mafron with house-keeping duties. Salary £120 per annum, with furnished apartments in the hospital, board, washing and uniform. Applications to John L. Worsfold, Clerk and Receiver, Bridewell Royal Hospital, London, E.C. (See advt.)

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Charlestown, co. Mayo; Harrow, Middlesex.

London Fever Hospital, Liverpool Road, N.—Assistant Resident Medical Officer. Salary £200 per annum, with residence and board. Applications to the Secretary.

Ingham Infirmary and South Shields and Westoe Dispensary.—House Surgeon. Salary £150 per annum, with residence, board, and washing. Applications to John Potter, Secretary, Ingham Infirmary, South Shields.

Royal Victoria and West Hants Hospital, Bournemouth.—House Surgeon. Salary £150 per annum, with board, lodging, and washing. Applications to Gordon M. Saul, Secretary.

The Great Hospital, Dudley.—Assistant House Surgeon. Salary £120 per annum, with residence, board, and washing. Applications to the Secretary.

Royal Surrey County Hospital, Guildford.—House Surgeon. Salary £150 per annum, with board, residence, and laundry. Applications to the Secretary.

Bolton Infirmary and Dispensary.—Second House Surgeon. Salary £200 per annum, with apartments, board, and attendance. Applications to Albert E. Briscoe, Secretary.

Appointments.

MAYSTON, J. H., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory and Workshop Acts for the Hackney District of the county of London.

MERRICK, W. J., M.B., Ch.B. Dub., Certifying Surgeon under the Factory and Workshop Acts for the Castleknock District of the county of Dublin.

COCHRANE, S. T., M.D. Durh., D.P.H., District Medical Officer of the Burton-upon-Trent Union.

GORDON, F. J., B.A. Camb., M.R.C.S., L.R.C.P., District Medical Officer of the Horncastle Union.

GRAVES, A. J., M.R.C.S., L.R.C.P., District Medical Officer of the Whitehaven Union.

HARRY, W. B., L.S.A., District Medical Officer of the Neath Union.

LEONARD, T. J., L.R.C.P. and S.I., Certifying Factory Surgeon for the Glaslough District, co. Monaghan.

NALLIAH, N. R., L.R.C.P., M.R.C.S., Assistant House Surgeon to the West Bromwich and District Hospital.

Births.

FOULKES.—On March 5th, at 62 Croydon Road, Beckenham, the wife of Peter Foulkes, M.B., Aveley, Purfleet, of a son.

LEA.—On February 25th, at Inglewood, Denmark Hill, the wife of Captain E. T. H. Lea, R.A.M.C., a son.

ORME.—On March 3rd, at Amphil, Bedfordshire, the wife of R. Henry Orme, of a daughter (still-born).

PANKRIDGE.—On March 2nd, at Petersfield, Hants, the wife of W. P. Pankridge, M.B., M.R.C.S., L.R.C.P., of a son.

Marriages.

PHILLIPS—GANBRILL.—On March 3rd, at the Parish Church, Edgbaston, Birmingham, Capt. Alfred Percy Phillips, R.A.M.C., third son of G. A. Phillips, Esq., J.P., of Hardwick Lodge, Streety, to Norah, third daughter of N. S. Ganbrill, Esq., Brockley, S.E.

THOMSON—FREAM.—On February 29th, at St. James's Church, Paddington, W., Thomas Theodore Thomson, M.B., Ch.B., of the London Missionary Society, Jammalamaduga, South India, to Philippine, daughter of Ralph Fream, Esq., of Gloucester.

TOLLER—COURT.—On March 1st, at St. Peter's Church, Malvern Wells, Charles W. E. Toller, M.D., of Ilracombe, only son of the late C. H. Toller, Esq., late Commissariat Dept., to Ella Milward Court, of Shelsley, Malvern Wells, elder daughter of the late Philip Wathen Court, of Tankatara, Port Elizabeth.

Deaths.

BERDOE.—On March 2nd, at 121 Bishops Road, Victoria Park, N.E., Dr. Edward Berdoe, in his 79th year.

BLASSON.—On March 2nd, of pneumonia, Thomas Blasson, M.R.C.S., L.S.A., of Billingboro', aged 81.

COLLINS.—On March 2nd, at Redstede, East Grinstead, suddenly, Charles Edward Collins, M.R.C.S. Eng., L.R.C.P. Lond.

MAXWELL.—On March 6th, after an operation, Richard Drummond Maxwell, M.D., F.R.C.S. (Dick), of 7, Devonshire Street, W., Junior Obstetric Surgeon to the London Hospital.

MOORHEAD.—On March 1st, at Kyrle, Bathaston, while on sick leave, Brevet Colonel A. H. Moorhead, I.M.S., A.D.M.S.

NICHOLLS.—On February 22nd, in India, from accidental gunshot wound, W. Howard Nicholls, Captain, R.A.M.C.

STANDERT.—On March 3rd, after a few days' illness, at 12 Montrell Road, Streatham Hill, S.W., Arthur Wyndham Standert, M.A., M.B., Corpus Christi College, Cantab., in his 69th year.

WATSON.—On March 4th, William Tyndale Watson, M.D., D.P.H., of Roslin, Grove Park, S.E., aged 76.

WILLS.—On February 25th, at Bexhill-on-Sea, Joseph Pearce Wills, M.D., aged 63 years.

WINTERBOTTOM.—On March 1st, at 1 Ella Road, Crouch Hill, N., Annie, second daughter of the late E. J. Winterbottom, of Sloane Street, S.W.

WORTH.—At Johannesburg, S. Africa, Francis James Worth, M.D., of Winton House, Basingstoke.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, MARCH 15, 1916.

No. 11.

AT THE PERIPHERY.

"*Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer.*"—BEAUMARCHAIS.

THE Central Medical War Committee, having shown what it can accomplish in the way of offensive circulars is now apparently settling down to render itself ridiculous—a

A Circular.

task which is well within its otherwise limited capacity. On page 592 of the *Lancet* of March 11th there appears the text of a circular which has been issued by the Central War Committee to canvassers. I am surprised and shocked that our grave, respectable and highly-esteemed contemporary should display such skittishness as to publish a circular which was clearly intended for *Punch*. The war is having a curious effect upon many, but no one ever supposed that it could move the *Lancet* to levity. It would have surprised me less to see an archbishop on a tight-rope.

Objections.

THE circular deals with certain "stock objections against enrolling" which the canvasser "may have to meet with brief answers." Thus:

Objection (a): I am physically

unfit. *Answer:* That is no reason why you should not have your proper certificate of enrolment, which will be proof that you are willing to go if the War Office needed and would take you.

Objection (b): I have financial liabilities which make it almost impossible to go. *Answer:* So have probably two-thirds of the men who enrol.

Objection (c): I have a partner or assistant who is on military service; or I am doing work for a neighbour on active service. *Answer:* Enrol all the same. Your position is bound to appeal to the Central and Local War Committee when they decide who are the men who should be asked to go.

Objection (j): I have special experience or qualifications, and I don't care to join unless *I shall be sure* (the italics are mine) they will be used.

Answer: It is impossible to give a guarantee that every man will be used only in the special line to which he has been accustomed." These objections and answers are faithfully transcribed, but the answers are not complete. In each case, however, the quality of the whole, both as to wording and purport, may be gauged by the sample.

I DON'T know how the canvassers who are expected to purvey this sort of sweet reasonableness are likely to be dressed, but they would be well advised to don a steel helmet and

Pleasantries.

some adequate protection for the gluteal region. The canvasee is not at the moment in a jocular mood, and however funny it might in ordinary circumstances appear to him, a medical man, to be

told that physical unfitnes is no barrier to military employment, that it will relieve his own financial liabilities to know that others have made sacrifices, or that a Central or Local War Committee is a better judge than he is as to whether he can be spared from his present employment, he is liable at present to regard such pleasantries as singularly ill-timed, and may easily be incited thereby to a form of badinage which is more vigorous than polite.

Pertinent.

BUT the reply to the very reasonable and most pertinent objection that the objector has special experience and qualifications is really the gem of this collection of comicalities. *Entre parenthèse*, I may be allowed to express the hope that the objector, when objecting, will express himself in English more grammatical than that which the Central Medical War Committee puts into his mouth. To say "that it is impossible to give a guarantee that every man will be used only in the special line to which he is accustomed" is the most complete confession of bungling ineptitude which could possibly be imagined. But it is typical of the British Medical Association and all its works. The public, naturally enough, regard all medical men as "doctors"; they cannot be expected to realise the enormous gulfs which separate the knowledge, experience, and efficiency of specialists in the various branches, not only from each other, but from what may be called ordinary medical practice. But the British Medical Association is fully cognisant of these distinctions, and the paramount importance of intelligent differentiation between doctor and doctor where military services are concerned ought not to be beyond the scope of its appreciation. And yet its reply to this very cogent objection is the typically Prussian "It is impossible"

Impertinent.

BUT what is it that is impossible? It is impossible to give a guarantee that a man will be given suitable work to do; that a surgeon will be given surgery; an oculist eye work; an anæsthetist, anæsthetics; a radiologist, X-ray work. These and other specialists have seemingly but one simple duty before them—that of delivering themselves bound hand and foot to the tender mercies of a committee of an Association which has ever been conspicuous for its jealousy of, and paltriness towards, experts and specialists. To dare to know more than your neighbour on any particular subject has always been a sure passport to the distinction of being belittled by this muddling mush of mediocrities.

In peace time that is a laughing matter, but in war time it is a serious one. The profession as a whole, and each man in it, is anxious to do the best possible under the trying circumstances; and what is the help or guidance which they are offered? Having, by some extraordinary *maladresse*, on the part of the War Office, succeeded in obtaining official recognition, this Committee immediately adopts the tone and language of the Jack-in-office. "Objections? Difficulties? Nonsense! Go and enrol!"

Credit.

The circular says: "The credit of the whole profession is at stake in making this enrolment scheme a success." The credit of the profession is not at stake. The credit of the profession, always high where charity, loyalty and self-sacrifice are concerned, has been more than abundantly vindicated since the outbreak of war. Whoever else has faltered or failed, the doctors at any rate have been true to their traditions and have staunchly upheld the dignity and responsibility of their calling. The credit of the profession is not and never was in danger. And it never will be in danger unless and until it becomes confused in men's minds with the credit of the British Medical Association. The British Medical Association is, and has for years been discredited, and it is apparently seeking to rehabilitate itself by the curious expedient of brow-beating and bullying the members of the profession, and by mismanaging affairs with which it ought never to have been entrusted.

An Interview.

QUITE recently some dozen medical men representing various branches of the profession went as a deputation to the Central War Committee earnestly seeking to be enlightened about some of the important matters which are exercising the minds of many. The conference was not a success. If I am correctly informed, the questions asked by the visitors evoked more heat than light from the members of the Committee. The questions were definite, but they appear to have been met in the first instance by vague, high-sounding generalities, patriotism and belated balderdash of that kind; but when replies as definite as the questions were pressed for, the vagueness disappeared and the sound became predominant. Voices were raised, the table was thumped, but the stalwart dozen stood firm. The only answer which they seem to have elicited took the form of a peremptory order to each one to enlist at once under pain of being regarded and treated as a blackleg. Here, indeed, are courtesy, tact, and diplomacy, as these things are understood and practised at Potsdam.

Dissatisfaction.

It is really high time that the Director-General took notice of the deep and growing dissatisfaction which the Central War Committee and its methods have created in the profession at large. I repeat that there is not a man in the medical profession who is not willing at whatever sacrifice to respond to the call of the country as expressed by the properly constituted authorities. If Sir Alfred Keogh and Mr. Tennant tell him he is wanted, every medical man of military age, or even of more than military age, will cheerfully do the work which is allotted to him. But the mouthpiece of these officials must be something other than this self-elected Committee of the B.M.A., which has succeeded in irritating everyone and in satisfying no one. The profession demands a body to whose judgment, impartiality, sympathy and loyalty it can pin its faith, a body in whose hands it can place its affairs with confidence that the interests of the profession at large and not those of the British Medical Association will be the first consideration.

The B.M.A.

We have always contended in the MEDICAL PRESS AND CIRCULAR that work of this national character and serious import should be entrusted to a national and not to a sectarian body. We suggested the General Medical Council as a suitable authority, ready to hand. It was then pointed out that there were serious, and even insuperable difficulties in the path of such a scheme, and we were told that the British Medical Association, having the necessary organisation, and having obtained the necessary recognition, was practically the only available body. Now, it is perfectly obvious that the British Medical Association is quite unequal to the task which it has arrogantly assumed. In the full height of its wasting disease it was seized with the grandiose notions of the general paralytic; its speech became blurred, its vision impaired, its gait ataxic, its manners atrocious. The diagnosis is no longer in doubt. The pettifogging suburban attorney masquerades in the hired robes of a Lord Chancellor and persuades himself that he is a great and respected National Institution. And the devil of it is that he has managed to persuade others.

Substitute.

Now, it is quite obvious that this mockery and mummery must cease. The obvious difficulty of finding a suitable substitute should not be left to the Director-General to solve. He has already enough to occupy him. The difficulty, nevertheless, must be solved, and solved quickly, and I suggest that an *ad hoc* representative committee from the two Royal Colleges of Physicians and Surgeons of London for England should be appointed at once. Such a body would command the instant and complete confidence of the profession, and even if it did not immediately take over the work of the Central War Committee, it would act as a Court of Appeal from the ill-digested decisions and the clumsily expressed suggestions of the last-named. The Councils of the two Royal Colleges have an opportunity of saving the profession from a very real and pressing difficulty, and it is sincerely to be hoped that they will realise their responsibility. The appointment of such a committee would necessarily and inevitably be followed by official recognition, and its existence would bring a sense of peace and security to the profession as a whole.

JUST as we are going to press, a letter has arrived from Dr. Maurice Central Medical Hayes, the Secretary of the Irish War Committee. Medical War Committee, enclosing some correspondence between himself and Sir Alfred Keogh. It is too long for insertion in this issue, but it will appear next week. I shall then deal fully with the subject to which it refers. In the meantime I wish to make it quite clear that my remarks concerning the English Central Medical War Committee have no reference to the Irish Medical War Committee, or to the body which acts in a similar capacity in Scotland. I have criticised the English Central War Committee, both as to its constitution and its methods. I have not referred to the Irish Central War Committee either directly or by implication. I know nothing about its constitution, and I am quite ready to believe that it brings to its task of recruiting, the good sense, the tact, and the sympathy which have been so conspicuously wanting in the body which sits at 429 Strand, London. It seems necessary to add, curious as it may seem, that I have never sought to discourage medical recruiting. My object has been to further it, and to that end I have ventured to suggest a change of personnel and method, not in Ireland, but in England, and particularly in London. SINAPIS.

OF BLOOD PRESSURE.

It is not so very long ago since the profession, as a whole, came to the realisation that the estimation of blood pressure was a clinical measure of considerable importance. In the beginning of its evolution skilful observers would record the impression given by the pulse to the examining finger, and a "hard" pulse was regarded as an indication for blood-letting. Sir Thomas Watson (1792-1882), in his celebrated "Lectures on the Principles and Practice of Physic," first published in 1843, says: "The quality of the pulse which bespeaks the necessity for bloodletting is hardness. The hardness is ascertained and measured by the resistance which the throb of the artery makes to your finger. The pulse is sometimes said to be incompressible; which means that although you apply your finger with considerable firmness, the blood still forces its way through the vessel beneath it." The first attempt at the instrumental, that is the accurate measurement of blood pressure, was made by Vierordt in 1855, and he was followed at various intervals by Von Basch, Marey, Potain, Riva-Rocci, Leonard Hill and George Oliver. "The history of the successive methods," says Janeway, "is a long one, not always free from rancour and jealousy, when a cherished instrument had done its best service in the unexpected way of suggesting a better one." That inventors should have their jealousies is not surprising, for that is the way in which they display their superiority over ordinary mortals. What is surprising is that there should be clinicians to-day who cling to and hold fast by the digital method of estimating blood pressure, and decline altogether to admit that a manometer can afford them any information which is not to be obtained by the primitive palpation of the radial artery. And yet such, alas! there be. But in spite of them the general practitioner has learnt to use the manometer; the handling, reading and interpreting of it are easy; it impresses the patient; occasionally, and often unexpectedly, it yields information of paramount importance. Like its forbear the sphygmograph, too much was at first expected of it, and there were puzzlements and disappointments leading in some cases to impatience and even abuse. It remains, however, and will always remain an instrument of precision, whose assistance no conscientious practitioner can afford to neglect.

There are various instruments on the market, all of which may be trusted for substantial accuracy. The selection is therefore a matter of taste and convenience. For portability the pocket instrument devised by Leonard Hill must be given the first place, but it has inconveniences which with many people outweigh this advantage. There are several spring instruments and many mercurial, some of which are portable and some suitable only for the consulting room. For very accurate observations, such as are necessary to physiological investigations, a mercurial instrument is said to be preferred. It is unfortunate that most of the good blood pressure instruments should still be rather expensive, but that is a matter which time alone can remedy.

The sensation of a "hard" pulse, especially if as

well as hard the vessel seems small, is recognised as a direct invitation to the use of a manometer, but it is less often recognised that a loud, especially a clanging second sound at the aortic cartilage should remind the physician even more forcibly that an accurate reading is required. Nervous patients, especially when being examined for the first time or for life assurance, often present this noisy second sound, the real significance of which the manometer will readily reveal to the really skilled observer.

But the recognition and accurate recording of so-called high tension is by no means the only service which an efficient manometer may render to the practitioner. For even when he has discovered and measured a blood pressure which is above the normal limits he may be powerless to reduce it. He may even be foolish in attempting to do so. For high blood pressure may threaten the integrity of the arteries—in the long run it must do so—but there are even worse things than menaced vessels. If the conditions be such that in order physiologically to feed the medulla the general pressure must be raised, then the raised pressure cannot obviously with safety be reduced. With the medulla starved, or even for a moment deprived of its due share of circulating food, the whole machine drops inevitably and without hope of recovery into eternal silence. High tension is a potential danger, but really low tension is a present and pressing jeopardy. To reduce a high reading, as may easily be done with amyl nitrite, to what in ordinary circumstances would be a normal reading, may, in the circumstances be an extremely risky measure, for the high reading may indicate a defensive position deliberately adopted by the medulla; and the reduction, though it may look normal as measured in mm. Hg. may represent in reality a position of collapse, from which, if the patient is to be rescued, it can only be by raising the pressure which we have been at such pains to reduce. As Goodman puts it, "High blood pressure is often a necessary accompaniment of altered function and structure, and were it not for this raised blood pressure, life could not be carried on with these functional or organic changes." The manometer is now extensively used in assurance work, and it has frequently afforded the examining officer an excuse for loading a life which formerly his unaided clinical instinct incited him to load, for which recommendation he was nevertheless often at a loss for a reason which would satisfy his Board.

The manometer, helpful and even essential as it is, must nevertheless not be regarded as comprising all the law and the prophets. There are circulatory diseases of a very deadly description, forms of arterial degeneration, for example, in which manometer readings might easily lull the examiner into a false sense of security, for it would record neither hypertension nor hypotension. Like everything else in clinical medicine, it offers no royal road. It is an admirable servant, but an atrocious master. Its revelations must be seen in their due perspective with other findings, but to decline to profit by its assistance is no longer in consonance with the dignity of a self-respecting practitioner of the healing art.

CURRENT TOPICS.

Royal Edinburgh Mental Hospital.

WE have received a copy of the annual report of the above hospital for the year 1915, being the one-hundred-and-third since the opening of the institution. It is a record of strenuous endeavour, of good work accomplished under serious difficulty, and reflects the greatest credit on the able physician-superintendent, Dr. G. M. Robertson, and his staff. The number of patients during the year increased from 800 to 889. The number of admissions was 462, of discharges, 238, and of deaths 135.

Referring particularly to the West House, which accommodates patients of the poorer class, Dr. Robertson points out that the number of admissions is almost exactly two-and-a-half times the average admission rate of the previous six years. This is entirely due to the magnanimous and public spirited offer of the managers to receive all cases of occurring insanity in the city of Edinburgh. By this means, Banjou Village Asylum was relieved, and set free to be converted into one of the largest and best equipped military hospitals in the country. To add to the difficulties of such a large increase, three out of four of the assistant medical officers have joined the forces, while nearly half the staff of matrons and assistant matrons have taken posts in military hospitals. The superintendent points out that as he has always selected for these important positions fully-trained hospital nurses, they were eligible for military posts. He pays a tribute to those officials left behind to carry on the arduous work of the institution.

An interesting point in the report is the statement that "there is a definite fall in the amount of insanity traced to alcohol as an exciting cause in the case of both men and women, the percentages being 10 for the former and 3 for the latter, the total being 6.3 per cent. This is decidedly below the normal, and if it be the case that there is increased drinking among women who receive separation allowances, it must be of such a nature that it does not tend to produce insanity. It is well-known that not occasional drinking bouts, but the habit of constant nipping is the form which is most deleterious to the nervous system." Dr. Robertson does not think that the war has increased the amount of insanity. Of soldier cases admitted, the majority had not been to the front. In a small number, alcoholic excess was assigned as the cause of insanity. Two types of insanity stood out prominently in the military cases. There was first a considerable number of cases of simple mental excitement or mania. It would appear that in these cases the excitement produced by their new environment and military duties, and the high tension under which they lived had overstepped the normal. They were perfectly lucid in intellect, but very exalted in feeling.

The second group of cases consisted of high-grade mental defectives. These men had passed the physical tests when they enlisted, and had answered the few questions addressed to them without displaying their mental deficiency. It was very soon found, however, that owing to their low level of intelligence they were quite unfit to be trained as soldiers or to realise their responsibilities. The physician-superintendent shrewdly observes that had the Mental Deficiency Act been in force for some years, no doubt they would all have been known to the authorities. Dr. Robertson pays a graceful tribute to the worth and work of his distinguished predecessor, the late Sir Thomas Clouston.

The whole report spells efficiency, and no greater tribute can be paid to the physician-superintendent and his staff than to express the belief that the work of the late distinguished head is being worthily carried on.

Doctors on Active Service.

THE majority of the medical men in Partick and district have accepted a scheme for attending to the practices of their fellow practitioners who are on active service.

Each doctor going on active service appoints a representative to transact all business (financial and other) with the secretary. Where no special arrangements have been made by the doctor, his panel patients will be distributed by the Society according to locality. Private patients may make their own arrangements with any member of the Society for attendance which will be given on behalf of the doctor on service; and practitioners remaining at home pledge themselves not to accept patients of absent doctors as their own during the war, or within one year of the doctor's return, without his consent. Payments in respect of panel patients will be divided on the basis of 60 per cent. to the doctor on service, subject to the deduction of clerical expenses, and 40 per cent. to the acting doctor. Fees for private patients are to be equally divided, with the exception that the acting doctor shall retain the whole fee in the case of midwifery cases and miscarriages, administration of general anaesthetics, removal of tonsils, and like operations, lunacy and life insurance certificates, legal reports and court attendance, and notification of infectious diseases. Accounts will be rendered half-yearly by the acting doctor, who will make a half-yearly statement and settlement to the representative of the absent doctor.

Should the doctor die on service or be incapacitated, or remain permanently in the army, the Society undertakes to assist in the advantageous disposal of the practice. Each acting doctor will hand to the representative the list of panel and private patients he has attended, and in the event of patients of a deceased or disabled doctor desiring to retain the services of the acting doctor, the latter shall pay to the representative half the fees paid for work during the ensuing year, with the exception of those enumerated above.

Public Health of Middlesex for 1914.

THE annual report for 1914 of Dr. C. W. F. Young, the Medical Officer of Health for Middlesex, includes also a summary of the annual reports of the District Medical Officers of Health in the county. The county is very populous. The area of the administrative county is 148,700 acres. By making necessary corrections a statistical population of 1,235,065 is obtained, and it is this figure upon which the various county rates are calculated. The number of births for the county in 1914 was 28,147, as compared with 27,719 and 27,576 in 1913 and 1912 respectively. This number is equivalent to a birth-rate of 22.8 per 1,000 persons living as compared with 23.0 and 23.6 in the two previous years. It is the lowest rate recorded since 1900. In 1901 the birth-rate was 28.1 per 1,000, and in 1904 it was 29.7, but since the latter date there has been a steady and continuous decrease. The decrease is not limited to Middlesex, but has been noticeable in the country generally. The birth-rates vary considerably in different parts of the county. The lowest—viz., 17.0 and 17.5—are recorded in the Boroughs of Hornsey and Ealing respectively, whilst the highest occurred in Brentford 28.0, Edmonton 27.4, Friern Barnet 26.4, and Tottenham and Wealdstone 86.0 each.

The corrected number of deaths is 12,564. In the three previous years, 1913, 1912, and 1911, the number was 12,405, 11,685, and 13,262 respectively. The death-rate for 1914 is 10.1. Compared with previous years it is lower than any rate since 1900.

The diseases which contributed to make up the total of 12,564 deaths were:—Heart diseases, 1,278 or about 1-10th; tuberculosis (all forms), 1,219 or about 1-10th; cancer, 1,190; pneumonia, 920; congenital debility, malformation and premature birth, 862; bronchitis, 838. Of the deaths from tuberculosis, 957 were registered as due to the pulmonary form, and of these, 633 were deaths amongst persons between the ages of 15 and 45 years.

The total number of deaths of children under one year of age, after correction, was 2,172, equal to an infant mortality of 77.2 per 1,000 children born. This is the lowest rate since 1900. Ever since the year 1906, when the rate was 121, it has steadily decreased, and has been below 100, except in 1911, when the rate was 119.

Neo-Biology.

THIS is from Carrick, where they breed men. An elderly naval man, grizzily bearded, with Bell's palsy causing his words to come out where his buccinator ought to be, but wasn't, spoke thuswise, of course in Doric.

"We're fearfully and wonderfully made: we irr that. But dinna rin awa' wi' the notion that natur' never makes mistakes. Noo, luk here, what's the sense in pittin' your shin-bane in the front o' your leg? It's fair, clotted nonsense. Ye see, it's always in front you get the dunts, like when you're rinning along the deck at night. Wouldn't it be far mair sensible if the calf of your leg was in front? The saft padding wouldn't feel the blow. And there would be a heap less sveerin'.

"That's no a' eyther. Noo, jist look at a cat's face. It's no use whatever for catching mice. When a mouse gets into a hole the cat is fair on her beam-ends: she's stuck. But if she had a neb like a whaup (a bill like a curlew)." etc., etc.

The argument from design has not the grip on Covenanted Carrick that it had in the days of Sawney Peden.

The Severity of Typhoid Fever.

WE have been accustomed to regard paratyphoid fever as a comparatively mild disease, rarely giving rise to serious symptoms or leading to a fatal result. So few, indeed, have been the recorded deaths that there has been little opportunity for *post mortem* research, and our knowledge of the pathology of the disease has been scanty. Fatal cases have, however, been observed, and in the current number of the *Quarterly Journal of Medicine*, Drs. Bertrand Dawson and T. H. Whittington give us a careful study of seventeen such cases which have come under their notice. Two were cases of infection with paratyphoid A, and fifteen with paratyphoid B. In severe cases the disease so closely resembled typhoid that a diagnosis could only be made by laboratory findings. The respiratory system suffered in nearly every case, in degrees varying from "congestion" to acute gangrenous pneumonia. The spleen does not appear to have been enlarged with at all the same frequency as in typhoid. The lesions found *post mortem* in the intestines seem to have been quite as severe as in typhoid, but the large intestine was more frequently affected than in typhoid. In three cases the appendix was gravely affected. As might be expected from the severity of the intestinal lesions diarrhoea was frequent, and hæmorrhage occurred in several cases. The

observers noted a tendency to the formation of pus, abscesses of the spleen, of the liver, and of the lung being noted. It is clear that although paratyphoid is usually comparatively mild, it may reach to any degree of severity.

New Hospital for the West of Scotland.

ACTIVE steps are being taken to found a hospital somewhere in the West of Scotland for such soldiers and sailors belonging to the district as have lost a limb or otherwise been disabled. It is to do the same kind of work as the present hospital at Roehampton. It is meant to be directly under the control of the War Office and the Admiralty conjointly. That there is need for such an agency is evident from the fact that over a thousand names are on the waiting list for the Roehampton institution. The presence on the Committee of the names of Lord Provost Dunlop, the Marquis of Ailsa, the Marchioness of Bute, Sir William Macewen, Prof. and Mrs. Archibald Barr, Messrs. David McCowan, Reid and Yarrow, connotes business energy and professional knowledge ample to carry out the measure well and speedily. The Committee were sympathetically received by both military and naval authorities. Which is right, for this summer is certain, unhappily, to increase very largely the waiting list above referred to.

Pedology.

STUDY of our American contemporaries impresses us with the thoroughness of transatlantic treatment in the case of the subnormal, deficient, or hypoplastic child. Clinical manifestations which amongst us receive scant attention, or which, from continual occurrence, have come to be regarded as well-nigh inseparable from childhood, in the hands of these pedologists develop into phenomena of significance. From stuttering to skull deformity stretches a chain of infantile aberrations, all stigmata of a subnormal constitution, in the widest sense of this latter. Causation, in the opinion of these experts, appears to lie mainly in perversion of internal secretion. The treatment suggested, therefore, is organo-therapy, so far as drugs are concerned, but such plays a minor role in comparison with the ordering of the small patient's life. We read of prolonged sun baths, the eyes alone protected from the beneficent rays; of swimming in open pools, a similar procedure indoors being considered useless; of nights passed sleeping under the stars. This for the case of obscure ætiology. Congenital organic taints, such as lues, receive in addition their specific remedies. While finding nothing but praise for all attempts to mould child life to its absolute possibilities, we incline to regard such efforts as mainly symptomatic. They merely give the little human animal an extenuation, what is surely his by absolute right of birth. The small boy, for instance, leading a normal life in proper surroundings, instinctively takes his swim and sun bath without any suggestion that he should do so. So long as overstrain and overcrowding, and absence of contact with the earth and the clear air encasing it is denied by giant circumstance to fathers and mothers, so long will they continue to produce the child which the Americans class as hypoplastic.

Presentation to Dr. J. Power, Ardfinnan.

WE are glad to learn that the presentation to Dr. J. Power, to which we called attention some weeks ago, is receiving generous support. As we are sure that there are many others who would wish to subscribe, we would remind them that it is intended to close the list on the 25th inst.

ORIGINAL PAPERS.

THE BLOOD PRESSURE IN TYPHOID FEVER.

By J. D. ROLLESTON, M.D.

Assistant Medical Officer, Grove Fever Hospital, London.

HISTORICAL NOTE.

HUCHARD (10), in 1889, was the first to draw attention to the tendency of typhoid fever to cause a fall in the blood-pressure, and showed that this hypotension could be recognised in the absence of any special apparatus, not only by the diastolic and compressibility of the pulse, but also by the weakness of the aortic diastolic sound and foetal rhythm of the heart.

Alezais and François (1), in examination of 150 cases of typhoid fever with Verdin's instrument, confirmed Huchard's views, and showed that hypotension, which sometimes occurred at an early stage, might be present in mild or abortive attacks as well as in severe or moderate cases; while, on the other hand, very severe cases might retain to the end a relatively high blood-pressure.

Potain (14), who did so much to popularise the use of the sphygmomanometer in clinical medicine, laid down that typhoid fever lowers the blood-pressure more than any other acute disease. He pointed out, however, that the blood-pressure did not appear to bear any relation to the severity of the disease, as in a series of 116 cases the average blood-pressure of the fatal cases was about the same as of those who recovered.

Teissier (17) examined twelve cases in adults or adolescents with Potain's instrument. He did not find the irregularities of the blood-pressure at all extensive, but attributed the oscillations noted by Alezais and François to the character of their instrument. He concluded that a normal or raised blood-pressure in so regularly hypotensive a disease as typhoid fever was of bad significance, and indicated a complication or some pathological factor existing prior to the attack of typhoid.

Reynaud (15) examined 66 adolescent and adult typhoid cases with Verdin's instrument. Like Teissier, he found that far from presenting daily irregularities, the sphygmomanometric curve showed only slight oscillations in most of the cases which recovered. The highest tension he found coincided with the fall of temperature to normal, or sometimes preceded it by a few days. In convalescence the rise was always slow. Even after mild attacks, a large number of patients left the hospital between the 40th and 50th days without having regained their normal blood-pressure.

In fatal cases the terminal rise of the pulse-rate was always accompanied by extreme hypotension. In favourable cases the blood-pressure soon began to rise again, either as the result of treatment or spontaneously.

Durand-Viel (6) examined ten cases in children aged from 7 to 14 years with Potain's instrument, and found considerable hypotension even at the earliest stage of the disease. The older the child, the more marked was the hypotension. The blood-pressure remained low during convalescence, and only very slowly resumed its normal level.

Durand-Viel followed Potain in the view that there was no direct relation between the gravity of the attack and the fall of blood-pressure, as very low readings were found in quite mild cases.

Crile (5), in 1903, drew attention to the value of hypertension in the diagnosis of typhoid perforation. According to observation on 115 cases of typhoid fever with Riva-Rocci's instrument, the highest systolic pressure in uncomplicated cases was 138 mm., and the lowest 74 mm., whereas in 20 cases of acute peritonitis, five of which occurred in typhoid fever, the highest systolic pressure was 208 mm., and the lowest 156 mm.

Cook and Briggs (4) also found an early and striking rise of pressure in typhoid perforation and peritonitis during the period of peritoneal irritation, the hypertension being followed by rapid and profound depression.

Carrière and Dancourt (3) examined 41 cases in children with Potain's instrument. They found that moderate hypotension was the rule, but that hypertension sometimes occurred. Thus, three children had a pressure above normal throughout their disease, and in ten others, although the average blood-pressure was below normal, the tension at one time or another exceeded the normal.

A high blood-pressure was always met with one or more days before the occurrence of intestinal hæmorrhage, and fairly frequently accompanied pulmonary congestion, violent delirium, pericarditis, and sometimes myocarditis.

Weigert (19) examined 63 cases with Riva-Rocci's instrument. He found that the extent of the fall sometimes, though not frequently, depended on the severity of the attack. Hypotension was not entirely absent in mild cases. In severe cases which terminated favourably records as low as 72 mm. or 70 mm. were met with, apart from intestinal hæmorrhage or other serious complications. The rise of pressure in convalescence was very gradual, and subject to considerable oscillations, so that a normal blood-pressure was very seldom observed, in spite of a very long stay in hospital. Weigert did not attach any prognostic importance to the blood-pressure in typhoid fever.

Barach (2), in 1907, reported on 81 cases in which the records had been taken by the nurse four times daily with Stanton's sphygmomanometer. His main conclusions were as follows:—

(1) The blood-pressure falls from normal in typhoid fever after the patient has taken to his bed, stays down till convalescence is established, and then returns to normal.

(2) Typhoid is a disease with a pressure below 100.

(3) The diagnostic and prognostic value of the blood-pressure in typhoid fever is slight.

(4) No opinion could be given as to the value of sphygmomanometry as a guide to treatment in typhoid fever.

Koessler (12) (1913) examined thirteen girls and seven boys suffering from typhoid with Pachon's oscillometer, and confirmed the findings of her predecessors to the effect that typhoid fever was a definitely and strongly hypotensive disease. Though hypertension due to the fever might sometimes be met with at the onset, the rise was merely temporary, and only affected the maximum tension and

was constantly followed by a fall. The minimum tension always remained below normal. Recent monographs on blood pressure dwell on the importance of sphygmomanometry in typhoid fever. Thus, Faught (7) (1913) states that "daily estimations of the blood-pressure are an absolute necessity to the proper and intelligent conduct of a case of typhoid fever, and a chart should be carefully prepared and followed." G. W. Norris (13) (1914) also devotes several pages to the subject.

Considerable interest attaches to observations made on the blood-pressure of old typhoid fever cases. Thayer (18) (1904) examined the systolic blood-pressure of 189 persons whose attacks of typhoid had occurred at periods ranging from one month to thirteen years previously, and found that their average blood-pressure was uniformly higher than in healthy individuals who had never had the disease. Thus, whereas the highest record in 276 healthy persons was 180 mm., among the old typhoid cases there were 27 with a reading above 180, and 10 with a pressure of 200 or more. Another striking feature in Thayer's old typhoid cases was the frequency with which the radial arteries were palpable.

Similar observations on post-typhoid hypertension have recently been made by Groedel (9) (1915) with a "Tykos" sphygmomanometer on 275 convalescent typhoid soldiers at Spa in Belgium. One hundred and twenty-nine cases, or 46 per cent., showed hypertension, and only 37.5 per cent. gave a normal blood-pressure. Tachycardia was frequently associated with the hypertension, and also symptoms such as pain in the chest, palpitation, and shortness of breath. Groedel suggests that these symptoms may have been due to over-action of the thyroid gland in convalescence following the disturbance of its function during the acute stage of the disease.

As it will be seen from this *résumé* of the literature, considerable attention has been paid to the blood-pressure in typhoid fever on the Continent and in the United States, but no monograph, to my knowledge, has appeared on the subject in this country. The present paper is based on the study of 58 cases of typhoid fever admitted to the Grove Hospital in the course of the last two years (October, 1913—October, 1915). The clinical diagnosis in each case was confirmed by Widal's reaction. The blood-pressure was taken with C. J. Martin's modification of Riva-Rocci's sphygmomanometer. As in my previous studies of the blood-pressure in diphtheria and scarlet fever (16), the systolic pressure measured by the disappearance of the radial pulse was alone taken into consideration. As far as possible, the measurements were taken at the same time each day between 10.30 a.m. and noon—i.e., from one and a-half to three hours after food. During convalescence, comparative observations were made on the different readings in the recumbent and erect positions. Apart from the early fatal cases, the total period of observation ranged in the severe cases from six to seventeen weeks, in the moderate from five to ten weeks, and the mild from four to nine weeks.

AGE AND SEX.

Table I. shows that all the patients except 14 below the age of 15 were adolescents or adults. The youngest was aged 2 years, and oldest 61; 39 were males, 19 females.

Contrary to what was noted in the sphygmomanometry of diphtheria and scarlet fever, in which there was no apparent difference in the blood-pressure of any two individuals of different sexes, but of the same age and suffering from attacks of equal severity, the tension of the females showed a decided tendency to keep at a lower level than that of the males.

NORMAL BLOOD-PRESSURE.

As the blood-pressure of the patients prior to their attack of typhoid was not known, their readings must be compared with those recorded by other observers on normal individuals. According to Cook and Briggs, the normal blood-pressure of children up to the age of two years, as measured by their modification of Riva-Rocci's instrument, is from 75 to 90 mm., and of children above that age 90 to 110 mm. As regards adults, Fisher's (8) figures compiled from 19,339 records in two insurance companies may serve as a guide.

TABLE II.

NORMAL BLOOD-PRESSURE IN ADULTS.

Age.	Average Blood-pressure.
15—20 years.	119.85 mm. Hg.
21—25 "	122.76 "
26—30 "	123.65 "
31—35 "	123.74 "
36—40 "	126.96 "
41—45 "	128.56 "
46—50 "	130.57 "
51—55 "	132.13 "
56—60 "	134.76 "

Blood-pressure in Typhoid Fever.—Of the 58 cases under consideration, 54, or 93.8 per cent., showed for varying periods a subnormal pressure, as judged by Cook and Briggs' standard for children and Fisher's for adults. The four cases in which the blood-pressure was not lowered were all mild or moderate cases in children aged from 2 to 12 years. None showed any degree of hypertension in the acute stage, in convalescence, or in any of the complications of the disease.

Not only was the actual percentage of cases in this series showing a fall of blood-pressure much greater than that among my cases of diphtheria and scarlet fever, in whom it was 35.1 and 25 per cent. respectively, but the degree and duration of the fall were always much more pronounced. As will be seen below, the varying degrees of depression bore a direct relation to the severity of the attack. No less than 22 patients, or 45.8 per cent., who were discharged at periods varying between the 5th and 23rd weeks of disease, never regained the normal blood-pressure for their age while in hospital.

In every case the first reading was considerably the highest, probably owing to the emotion caused by the application of an unfamiliar instrument.

The course of the blood-pressure was progressively downwards, no rise being noted before hæmorrhage or at the onset of perforation, as observed by some writers. A slight rise might sometimes occur at the onset of a relapse or on the occurrence of certain complications (*v. infra*), but was always of short duration.

A comparison of the maximum pressures observed during the febrile period with those regis-

tered during apyrexia gave the following results. The record taken on admission in each case was excluded. Among 42 cases in whom these comparative readings were made, the maximum pressure in convalescence was higher than in the acute stage in 27, lower in 11, and the same in 4.

Out of 49 cases in which the blood-pressure was taken daily throughout their illness, in 42 it fell at some period below 100 mm., and remained above

The greatest fall below normal noted in this class was 50 mm., the least 10 mm., and the average 29.9 mm. The difference between the highest and lowest readings in an individual case was most marked in this class, the greatest difference between 52 mm. and the average 27 mm. In 9 cases, or 39.1 per cent., the blood-pressure was still subnormal on discharge from hospital between the 67th and 155th days.

TABLE III.
BLOOD-PRESSURE IN SEVERE CASES.

Age.	Sex.	Day of Disease on Admission.	Blood-pressure on Admission.	Subsequent Records.
42	Male	19th	130	110, 92, 90, 88, 78. Death from peritonitis on 32nd day.
24	Male	21st	104	94, 96, 90, 90, 60. Death from myocarditis on 41st day.
21	Male	13th	114	110, 104, 100, 90, 70. Death from hæmorrhage on 31st day.
17	Male	8th	106	98, 96, 94, 80, 96, 100, 94, 100, 110 on discharge on 72nd day.
41	Male	11th	100	92, 90, 88, 80, 76, 90, 120 on discharge on 70th day.
31	Male	13th	110	100, 98, 96, 90, relapse, 96, 100, 106, 102, 2nd relapse, 106, 110, 104, 92, 84, 80, 90, 96, 98, 102, 108 on discharge on 155th day.
49	Female	23rd	106	100, 98, 96, 90, 100, relapse, 102, 104, 106, 100, 90, 86, 84, 100 on discharge on 114th day.

100 mm. in 7 only, 5 of whom were vigorous young men aged from 21 to 29, 1 a gouty man of 38, and 1 an arterio-sclerotic man of 51. In only two cases, men aged 23 and 54 respectively, did the blood-pressure rise above 130—viz., to 140 and 144, in each case on one occasion only. In only three others, all males, aged 15, 23, and 29, did the blood-pressure reach 130. The extent of the fall below normal varied from 10 to 50 mm., and the duration of the fall ranged from periods of 20 to 60 days.

Apart from the fatal cases, the blood-pressure

Class 2.—The fall of pressure, though decidedly less than in Class 1, was still considerable. In only one case was no hypotension noted. The cases given in Table IV. are typical.

The greatest fall below normal noted in this class was 40 mm., the least 0, and the average 21.6 mm. The greatest difference between the highest and lowest readings in a given case was 30 mm., and the average 17 mm. In 8 cases, or 44.4 per cent., the blood-pressure was still subnormal on discharge from hospital between the 48th and 77th days.

TABLE IV.
BLOOD-PRESSURE IN MODERATE CASES.

Age.	Sex.	Day of Disease on Admission.	Blood-pressure on Admission.	Subsequent Records.
6	Male	9th	110	100, 98, 94, 80, 86, 88, 90 on discharge on 44th day.
17	Female	8th	90	80, 76, 80, 86, 88, 90, 92, 100, 114 on discharge on 41st day.
24	Male	19th	114	110, 104, 102, 100, 102, 104, 108, 110, 120, 130 on discharge on 61st day.
27	Male	6th	122	116, 110, 108, 106, 110, 100, 96, 100, 110, 122 on discharge on 51st day.

fell to 80 mm. or below in 16 patients, 10 of whom were children aged from 2 to 14 years, and 6 adolescents or adults aged from 17 to 41. The lowest record, obtained in a patient who recovered, was 70 mm., which was noted during a period of ten days in a boy aged 8 years during a relapse.

Classification of Cases.—According to the severity of the attack the cases were grouped in three classes—Class 1 "severe" (23 cases), Class 2 "moderate" (18 cases), Class 3, "mild" (17 cases). Hypotension was present in all the severe cases (100 per cent.), in

Class 3.—The blood-pressure was least affected in this class. Three, in fact, showed no hypotension at all. The greatest fall below normal was 30 mm., the least 0, and the average 16.8 mm. The greatest difference between the highest and lowest records in a given case was 22 mm., and the average 14.2 mm. In 6 cases, or 35.8 per cent., the blood-pressure was still subnormal when the last observation was made between the 31st and 53rd days. Table V. shows typical readings.

Date of Highest and Lowest Readings.—Owing

TABLE V.
BLOOD-PRESSURE IN MILD CASES.

Age.	Sex.	Day of Disease on Admission.	Blood-pressure on Admission.	Subsequent Records.
12	Male	8th	104	100, 94, 100, 98, 108 on discharge on 41st day.
8	Female	10th	82	80, 80, 80, 78, 78, 90 on 46th day.
17	Female	15th	120	108, 100, 110 on discharge on 45th day.
23	Male	20th	120	116, 112, 110, 108, 116 on discharge on 52nd day.

whom it was also most pronounced; in all but one of the moderate cases (94 per cent.); and in all but three of the mild (82.3 per cent.).

Affection of the Blood-pressure in each Class.—Class 1: The hypotensive effect of typhoid fever was most marked and of longest duration in this class, in which every member was affected. The readings in Table III. may be regarded as typical.

to the difficulty of making a diagnosis of typhoid fever at an early stage of the disease, and to a reluctance to send cases to hospital before any other cause could be detected for the continued fever, comparatively few patients were admitted until the second week. Table VI. shows the date of admission in 48 cases in which the time of onset could be determined:—

TABLE VI.

DATE OF ADMISSION TO HOSPITAL.	
1st week	... 4 cases
2nd "	... 23 "
3rd "	... 12 "
4th "	... 8 "
5th "	... 1 case
	—
	48

In the great majority—viz., 35 cases, or 72.9 per cent., the highest readings were the first records taken. In the remaining 13 the highest records were not obtained until convalescence. In the great majority—viz., 51 out of 58 cases, or 87.9 per cent., the lowest readings were obtained before the end of the fourth week.

Except in three cases of relapse, the lowest readings were never found during the first week of the fever.

Comparative Readings in the Erect and Recumbent Positions.—The readings in the erect and recumbent positions in 44 patients in whom comparative observations were made were as follows:—In 6 the readings were the same, in 35 the blood-pressure was higher in the recumbent than in the erect position, and in 3 higher in the erect than in the recumbent, when the patient was first allowed to get up. Thus, in 41 patients, or 93.1 per cent., the reversal of the normal relations between the two records was found. The occurrence of this so-called "hypotension of effort," which I have already illustrated in the case of diphtheria and scarlet fever, in whom it was found in 77.6 and 48.4 per cent. respectively, is another proof of the hypotensive effect of typhoid fever. It is also of interest that whereas in the diphtheria and scarlet fever cases the normal relation was finally established before the patient left hospital, in six of the typhoid patients the hypotension of effort persisted until discharge. The hypotension of effort is often associated with other signs of cardio-vascular depression, such as weakness of the first sound, tachycardia, cyanosis, and coldness of the extremities. As I pointed out in my paper on the blood-pressure in diphtheria, the practical significance of this hypotension is to indicate that resumption of muscular work in such patients should be gradual, and should be accompanied, if necessary, by the administration of cardiac and vascular tonics.

Effect of Relapses and Complications on the Blood-pressure.—The occurrence of relapses had little effect upon the blood-pressure. Of 12 cases in which they occurred, in 5 there was no change at all, in 5 there was a transient rise of from 10 to 14 mm., and in 2 there was a fall of from 4 to 10 mm. It is noteworthy that in 4 cases the blood-pressure rose from 2 to 10 mm. one to four days before the onset of the relapse.

Intestinal Hæmorrhage occurred in nine cases. With the exception of three cases in which the hæmorrhage was slight and no change in the blood-pressure took place, there was a marked drop varying from 18 to 30 mm. In none was there any rise of blood-pressure prior to the hæmorrhage, as noted by Carrière and Dancourt.

Perforative Peritonitis.—Only two cases occurred. In neither was there the rise of pressure noted by Crile and by Cook and Briggs, but on the contrary a decided fall.

Albuminuria.—Twenty-seven cases showed this complication, but its occurrence did not appear to influence the blood-pressure in any way.

Pleurisy.—A case which developed this complication three days after admission showed a slight rise of tension, which temporarily interrupted the usual downward course of the blood-pressure.

Myocarditis occurred in one case, which showed a drop of 30 mm. in 24 hours.

Of the complications which developed in convalescence—viz., otitis (3 cases), periostitis (2 cases), myositis (2 cases), phlebitis (1 case), cholecystitis (1 case), none showed any influence on the blood-pressure except cholecystitis, which caused a rise ranging from 4 to 16 mm. for ten days.

A comparison of my results with those summarised in the historical introduction shows that my figures mainly confirm the investigations of previous observers.

The study of the blood-pressure in typhoid fever, as in other acute infections, adds to the interest of the disease, and is especially suitable for hospital practice, but it cannot be said to afford much guidance in diagnosis, prognosis or treatment. In this connection the recent pronouncement of Janeway (11) in a paper entitled "Important Contributions to Clinical Medicine during the past Thirty Years from the Study of the Human Blood-pressure," deserves to be quoted:—"In the early days of blood-pressure study, I, like most physicians interested in this field, hoped that it would furnish most important indications in acute infectious disease. That hope has been disappointed. I think that most of us must now agree with the conclusions of Kurt Weigert from his extensive studies of the acute infections, and which have been confirmed for scarlet fever by Rolleston, that the value of the blood-pressure measurement for prognosis in the acute infectious diseases is slight. It is an additional factor which is occasionally useful, as in typhoid patients with hæmorrhage, but for the most part the simpler observations made by our predecessors in clinical medicine of the facies, the tongue, the pulse, and the heart sounds, and the state of the nervous system, make the prognosis equally well without a knowledge of the blood-pressure curve."

SUMMARY.

(1) In a series of cases of typhoid fever the blood-pressure was found to be subnormal in 93.8 per cent., the extent and duration of the depression being, as a rule, in direct relation to the severity of the attack.

(2) The blood-pressure of the female patients showed a decided tendency to keep at a lower level than that of the males.

(3) A considerable percentage (45.8 per cent.) of the patients who were discharged at periods ranging from the 5th to the 23rd weeks of disease never regained the normal blood-pressure for their age during their stay in hospital.

(4) In the great majority of cases the blood-pressure fell below 100 mm. at some period of the disease.

(5) In the majority of cases the blood-pressure was higher in convalescence than in the acute stage.

(6) In 93.1 per cent. of the convalescent cases the readings in the recumbent and erect positions were the same, or the recumbent was higher than the vertical record until convalescence was firmly established, this "hypotension of effort" in some cases persisting until the patient's discharge.

(7) The only complications which affected the blood-pressure were intestinal hæmorrhage and myocarditis, which caused a considerable fall, and cholecystitis and pleurisy, which were accompanied by a transient rise.

(8) Though not essential for the successful management of a case, sphygmomanometry furnishes interesting illustrations of the profound effect produced on the cardio-vascular system by the toxins of typhoid fever.

HARVEY, DESCARTES, AND MOLIERE.*

By GEORGE PERNET, M.D.

It is well known that the publication of Harvey's "Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus" led to a great deal of virulent opposition on the part of the medical faculty. The circulationists and the anti-circulationists formed two contending camps, and, needless to say, the latter were far and away in the majority. But among the defenders of Harvey's ideas stood Descartes, one of the acutest thinkers of any time, and whose "Discours de la Méthode"—quite a small work, by the way—was destined vastly to influence philosophical thought and direct it into modern channels. René Descartes was born at La Haye, in Touraine, in 1595, and died at the age of 54, at Stockholm, in 1650. In his earlier years he travelled in various countries, as was the wont of those days, and took part in the siege of La Rochelle as a volunteer. I am indebted to a recent monograph by Professor Le Double, an anatomist of Tours, entitled, "Bossuet: Anatomiste et Physiologiste" (published in 1913), for the fact that Descartes paid a visit to England in 1631, not long, therefore, after the appearance of Harvey's *magnum opus* (1628), which revolutionised, slowly it is true, our conceptions of the blood-stream and its mechanism. It is probable that the French philosopher met the physician of Charles I. on that occasion, though there is nothing in the available correspondence of Descartes on the point. In any case, it was about that time that Descartes repeated Harvey's experiments and demonstrated them to friends in order to establish the truth of the new doctrine which so scandalised the medical and scientific world of that time. In his "Discours de la Méthode" (1637) Descartes refers to the circulation of the blood as ascertained by Harvey. In his second reply to Riolan, Harvey dwells on the support given to his doctrine by Descartes, to whom he refers as *vir acutissimus ingenio pollens*.

It may be asked how it came about that the great Bishop of Meaux, Bossuet—best known as the eloquent preacher of stately funeral orations—dabbled in anatomy and physiology. In the seventeenth and eighteenth centuries the Court, the Church, and the nobility and gentry (as runneth

the advertisement) took an interest in philosophy, especially that which went by the name of natural philosophy, and medicine. In England we need only recall, in passing, the Hon. Robert Boyle, Sir Christopher Wren, and the Rev. Stephen Hales, who conducted scientific experiments. In the Church have we not also Berkeley, the philosopher Bishop of Cloyne, who was not above writing on the virtues of tar-water? But of him more another time. In "Le Malade Imaginaire" Molière satirically refers to the anatomical dissections and demonstrations which were attended by the great—by the Dauphin of France himself, one of whose masters was Duverney, the anatomist. Molière was fond of ridiculing the faculty, as we all know. His Diafoirus was Guy Patin, one of the most bitter opponents of Harvey and the "circulators." Molière puts in the mouth of Diafoirus the following words in praise of his son, who had written a thesis against the new ideas: "Sur toute chose ce qui me plaît en lui et en quoi il suit mon exemple, c'est qu'il s'attache aveuglément aux opinions de nos Anciens et que jamais il n'a voulu comprendre ou écouter les raisons et les expériences des prétendues découvertes de notre siècle touchant la circulation du sang et autres opinions de la même farine." But it must be remembered, according to Dr. Le Double, that Molière's landlord was Dionis, a doctor and a pupil of Duverney. Between them there existed a bitter "landlord *versus* tenant" feud, which, no doubt, was the cause of the shafts of satire, which the comic writer so frequently aimed at the medical faculty. It should be added that Dr. Le Double's work contains, *inter alia*, a portrait of Descartes; but there is a better one, to my thinking, in Professor Bayliss's "Principles of General Physiology," just published (p. 38).

NOTE ON A NEW MEDIUM FOR PYELOGRAPHY.*

By ADAMS A. McCONNELL, F.R.C.S.I.,
Surgeon to the Richmond Hospital, Dublin.

It is a commonplace that the time for diagnosis of a disease is when the earliest evidence of its presence can be found, and that the diagnosis should include not only the gross pathological fact but also those finer details—subsidiary, causative or secondary—which may influence treatment and prognosis.

In most regions of the body we find that classical symptoms indicate an advanced pathological process, so advanced in many cases that surgery becomes a palliative rather than a curative measure.

When hydronephrosis has developed to the extent of causing reactive or atrophic changes in the renal tissue the symptoms are clear, and the presence of a tumour waxing and waning with corresponding decrease and increase in the amount of urine passed renders the diagnosis definite. But such a diagnosis is of infinitely less value than one arrived at before such pathological changes in the kidney have taken place. I believe that a diagnosis of hydronephrosis can be made at an early stage of its development only by special methods, the chief of which is the injection of the pelvis of the ureter with a substance opaque to X-rays. By this means the position, form, size, and capacity of the pelvis can be determined more accurately than by any other method, and variations can be discovered before permanent pathological damage has resulted.

The suspicion of early hydronephrosis is, perhaps, the chief indication for injecting substances into the

* Reprinted from the *West London Med.-Chir. Journal*.

*Read before the Section of Surgery in the Royal Academy of Medicine of Ireland, December 3rd, 1915.

pelvis of the ureter, for the symptoms may be of a very vague character; the chief symptom I have personally come across has been vague pain in the right side, sometimes behind the renal region, sometimes in front and simulating the pain produced by chronic appendicitis, stone in the gall-bladder and Jackson's membrane. The most marked hydronephrosis of which I have a picture was sent to hospital with the diagnosis of tumour of the stomach. If the right kidney is movable in such cases, it is, I think, imperative to determine whether hydronephrosis is present or not before removing the appendix or rendering the ascending colon more mobile or more fixed or removing it. In the literature several cases are reported in which the appendix, ovary, ascending colon, and gall-bladder have received surgical attention, when the real cause of the pain was hydronephrosis.

Pyelography is not only indicated when hydronephrosis is suspected, but in many other conditions the photograph obtained gives useful data for the elaboration of a diagnosis. Amongst my own cases I have two of tumours in the right loin, both of which possibly had their origin from the right kidney. By injecting the pelvis and taking an X-ray photograph, the kidney was seen to be distinct from the tumour; at operation one case proved to be cancer of the hepatic flexure of the colon, and the other to be a chronic abscess of the appendix.

Pyelography may, on occasion, therefore, save a patient an exploratory laparotomy or an exploration of the kidney.

I might quote the indications for pyelography from Thomson Walker thus:—

(1) As a means of making a diagnosis of early hydronephrosis, and of determining whether a movable kidney requires operation or not.

(2) In order to determine the relationship of the kidney to any doubtful abdominal tumour.

(3) In cases of unilateral hæmaturia to determine whether there is a growth in the kidney, for such a growth would probably modify the form of the pelvis of the ureter.

(4) In order to establish the relation between a supposed stone in the urinary tract and the renal area.

For some years collargol, a colloidal silver preparation, has been used as the medium for pyelography. Although other substances have been tried, such as iodide of silver, nothing until recently proved so generally satisfactory as collargol. I have used it in several cases without mishap, and have obtained many satisfactory results.

Before the war collargol was expensive, and since then it has become almost unprocurable. For this reason I cast about for a substitute on the English and American markets, but failed to find anything but silver iodide, which, in my hands, did not give as satisfactory results. So I interviewed Professor Caldwell, of the Royal College of Surgeons, Ireland, asking him for a salt opaque to the X-rays, harmless to the kidney, and capable of being injected along a fine ureteral catheter into the renal pelvis. Professor Caldwell said he thought he might be able to give me such a substance in the form of a bismuth compound. I pointed out, however, that various bismuth eruptions had been tried and failed, because bismuth became precipitated in the pelvis of the ureter, and might therefore form the basis of calculi. He told me that the preparation he would give me had never been tried, because it had never been made—that it would be of the consistency of milk, and that the whole amount would be washed out of the pelvis by the urine before precipitation could take place. I tried some of this in the case of a patient suffering from a vague pain in the right side, and obtained a picture of an early hydronephrosis. I used a 10 per cent.

solution of the substance, to which the provisional name of Skirol is given. It gives a better picture than any I have obtained with collargol, it has not caused any irritation in any of my patients, and has given me much useful information.

Several fatal results have been recorded after the injection of collargol into the pelvis. In some cases it has penetrated into the substance of the kidney and formed areas of necrosis. This has occurred most often when strong solutions (25 per cent.) have been used, and it is possible that collargol is an irritant when it comes into contact with the renal tissue. It is, however, not irritating to the mucous membrane of the pelvis and ureter.

From its constitution one would not expect the bismuth preparation, Skirol, to possess any irritating properties, and I have certainly found none on using it. The fatal results of collargol were in all probability due to rupture of the calices, by injecting the fluid at too great pressure; it should be allowed to flow in by gravity, not injected by force.

In my experience Skirol disappears from the pelvis more rapidly than collargol—a fact I consider advantageous. Collargol has been found in the pelvis from one to several weeks after injection. I have had some cases X-rayed one or two days after the injection of Skirol, and have not found any shadow.

The *technique* is simple. The patient is brought to the X-ray room and placed on a couch; a catheter is passed into the ureter and up to the pelvis, the X-ray plate is adjusted, and everything got ready to take the photograph at the right moment.

The fluid is then allowed to flow from a syringe held not more than 12 inches above the level of the kidney into the ureteral catheter.

The patient is told to say when pain is felt in the kidney—at that instant the injection is stopped and the photograph taken. The fluid is allowed to run out, and the catheter removed.

SOME IMPRESSIONS OF THE REPORT OF THE ROYAL COMMISSION ON VENEREAL DISEASES.

By WILLIAM A. BREND, M.D. (STATE MED.),
Lecturer on Forensic Medicine, Charing Cross Hospital.

THE Royal Commission on Venereal Diseases has carried through a most useful piece of work. It has collected information relating to these maladies from a large number of authorities, including medical men, statisticians, Government officials, and social reformers, and has set out this information in two large volumes of evidence, which form a most important compendium of knowledge on the subject. These volumes are really of greater value than the Report itself, and should be read in conjunction with the Report by all who associate themselves with the movement for the diminution of venereal diseases. The Report is also a valuable document, provided it be borne in mind that its authors did not consist of a body of exclusively scientific men directing their attention towards the elucidation of a scientific subject from an entirely unbiassed standpoint. The Commission consisted of some very eminent doctors, some of whom possessed strong views on the subject before their appointment, representatives of religious organisations, Government officials, and persons who have specially interested themselves in matters relating to women's welfare. The measures advocated, therefore, represent the views of a body of persons of very diverse character and experience, as to what can practically be applied to the community, regard being paid to considerations of moral and social importance besides those of a purely medical

nature. This is, of course, quite in accord with the object for which the Commission was appointed, and it is a tribute to the broad-mindedness of the members that they should have been unanimous in all their more important recommendations. Nevertheless, the inseparable association of moral questions with the prevalence of venereal disease, and the impossibility of arriving at unanimity on moral questions preclude the Report from being regarded as outside the domain of controversy, and already the opinion has been expressed that the Commission has failed to examine certain matters which may be of importance in reducing venereal disease.

THE PREVALENCE AND EFFECTS OF SYPHILIS.

The Commissioners have evidently and rightly been impressed with the magnitude of the evil, but it is doubtful whether this has been altogether an advantage, for it is impossible to read the Report and the evidence without gaining the impression that the Commissioners have painted an unjustifiably sombre picture, particularly as regards syphilis. It is true they point out that the statistical information is unreliable; nevertheless, they come to the conclusion that the number of persons who have been infected with syphilis, acquired or congenital, cannot fall below 10 per cent. of the whole population in large cities. It is impossible here to examine the evidence for this unexpectedly high estimate, but it does not seem conclusive. The figures were drawn mainly from not very satisfactory statistics relating to poor law, prison and asylum populations, but they were supplemented by special investigations undertaken by Sir John Collie, who found 9.36 of positive Wassermann reactions among 500 employees referred for medical report, and by Dr. Fildes, who found 8 to 12 per cent. of positive reactions among adult males, and 3 to 7 per cent. among adult females, in 1,002 patients and their friends who attended the London Hospital "for reasons wholly unconnected with syphilis." But neither of these can be regarded as typical samples of the whole population, and when the children are added, even allowing for congenital syphilis, it is difficult to see how the estimate of 10 per cent. is justified. Then the Commissioners say "infant deaths returned under 'congenital debility' and other headings are largely due to syphilis." But this is not at all in accord with the evidence of Dr. Stevenson, who pointed out that the distribution of infant deaths under the headings congenital debility and premature births is quite unlike that due to syphilis, and that whatever might be the number of deaths really due to syphilis, they were swamped by the very much larger number of deaths from other causes. Again, the Commissioners say that probably at least half the registered still-births are due to syphilis, referring for support to the views of Sir Thomas Barlow, Dr. Florence Willey and Dr. Frances Ivens. But admitting that the populations are not exactly comparable, Prof. Whitridge Williams found that syphilis was only responsible for 14 per cent. of foetal deaths among white women admitted to the Johns Hopkins Hospital, and there is reason to think that other researches now in hand will show this to be the more accurate figure. It is perhaps unfortunate that the Commissioners should have taken any line which may give colour to the statement that they have exaggerated the extent and effects of syphilis, as in any case the evil is of sufficient magnitude to justify all the measures in the way of increased facilities for diagnosis and treatment which are recommended.

HAS SYPHILIS DECLINED?

The Commissioners, after examining the evidence

relating to the prevalence of syphilis during the earlier decades, express their doubt as to whether there has been any reduction in the mortality justly attributable to syphilis in recent years. On the other hand, Dr. Stephenson, of the Registrar-General's office, was inclined to believe that there has been a genuine fall, and the reasons he gave for this view seem very convincing. The recorded mortality from syphilis shows a steady decrease, amounting to nearly 50 per cent. in the last 35 years. There is no doubt, of course, that the figures very substantially understate the actual mortality from syphilis, but there seems to be no reason to suppose that the error has varied much from year to year, and if it has not, then the statistics do show that there has been a very considerable fall. On this point, Dr. Stevenson pointed out that if the real incidence had remained constant, there are several important factors which would have made for a rise instead of a fall in the recorded deaths. In the first place there has been improvement in diagnosis, secondly, there has been a large increase in the proportion of deaths which occur in institutions, and these are much more likely to be accurately certified, and, thirdly, there has been a very large increase in the proportion of the urban population, and since syphilis is essentially a disease of large towns, this should have markedly increased the death rate. We may add to this the impression of nearly all the medical witnesses—many of them men of wide and long experience—that syphilis has shown a marked decline both in extent and virulence during the last two or three decades. It is not easy to see why the Commissioners should have hesitated to accept this view, supported as it is by the analogy presented by many other diseases which gradually wear themselves out in a community either by a process of widespread immunisation, or more probably, in consequence of a decline in the virulence of the infecting organism.

Associated with this question is the decrease in the number of recruits for the army rejected for syphilis, the rate having been 16.5 per 1,000 in 1873, 6.3 per 1,000 in 1890, and 1.4 per 1,000 in 1911-12. The Commissioners do not regard this as conclusive indication of decreasing prevalence of syphilis among the civil population, their reasons being that the signs of the disease are better known than formerly, and that men recognising these signs may not offer themselves as recruits; that recruiting sergeants, seeing that candidates are diseased, may tell them to get cured before presenting themselves for medical examination; and that there has been some confusion between soft chancre and syphilis. But as regards the first of these reasons, the signs of the disease to the non-medical affected individual are the same as they always were, and for the second it is difficult to believe that out of every thousand men, containing a dozen or so suffering from syphilis, who present themselves for enlistment, the recruiting sergeant is now able to detect all but one or two of the sufferers and send them off to be cured. Had the decline been slight, the reasons might have sufficed, but it is difficult to regard them as adequate, even collectively, to explain the great fall which has occurred.

The assessment of evidence is necessarily a matter of idiosyncrasy. Before I read this Report, I held the view, generally accepted I think among medical men, that there has been some decline in the virulence and probably in the prevalence of syphilis. The effect of reading carefully all the evidence, so far from leading me to the conclusion come to by the Commissioners, has been to strengthen my original view and induce the belief that the fall has been very much greater than I

had previously imagined. It must be pointed out that if there has been no decline in syphilis, then there is very little hope for the future. The Commissioners do not propose any new measures, but merely an extension of existing methods of dealing with the disease, such as increased facilities for diagnosis and treatment, greater instruction and warning of the young and so forth. Now while these services and influences are admittedly inadequate, they have by no means been non-existent in the past. Knowledge of methods of treatment has been steadily increasing, many parents warn their sons of the dangers of immoral behaviour, some teachers have private talks with their pupils, lock hospitals, general hospitals, rescue homes, leagues, associations of young men, etc., etc., have all been dealing with different aspects of the disease for many years, and if all these influences have had no effect in reducing the incidence of the disease in the past, we cannot expect their extension to have any greater effect in the future. If the Commissioners are right, we may well be pessimistic. If there has been a real fall, as I believe, we could have no greater encouragement to redouble our efforts and can look forward confidently to an eventual eradication of the disease.

PROPHYLAXIS.

A question of great importance is that of prophylactic measures against venereal diseases. Several of the witnesses considered that such precautions have been or may be of great value. Mr. Frank Kidd, for instance, said that if every adult male were to be instructed in precautionary measures against gonorrhœa, and followed the instruction, the disease would be stamped out in a few years. A certain number of lay persons, he added, have already learned this method, and for this reason alone the disease is becoming slightly less common amongst certain classes. Similar methods have been encouraged in the Navy, and in the opinion of competent authorities have had a substantial effect in reducing syphilis among sailors. It is interesting to note that since 1911 the Board of Trade has been supplying medicaments for this purpose to merchant ships. The German soldier is compelled to adopt prophylactic treatment after risk of infection, and venereal disease in the German Army is remarkably low. These facts, collected from the evidence and appendices, are sufficient to show that a critical examination of the value of prophylaxis and a discussion of the arguments for and against popularising these methods would have been of great utility. But the Commissioners completely avoid the subject in their Report. One can only infer the motives for this course, and it is easy to believe that they found themselves in a position of some difficulty. The objection would certainly be urged against these methods that by making illicit intercourse safer they were encouraging immorality, and it was therefore undesirable that the knowledge should be spread. But to discuss the question in the Report at all, even if they came to an adverse conclusion, would actually have the effect of giving the very publicity that was not desired. Hence, one must presume that for this reason it was decided to ignore the question altogether. This attitude will be approved or not, according to views of morality held, but it was quite a sound attitude for a Commission so constituted to adopt. The point really illustrates the great difficulty already referred to of dealing with a question in which medical, moral and social considerations are so closely interwoven. Possibly events may show that the Commission has made a mistake in not boldly facing the difficulty, for now that public attention has been called so strongly to the whole question, the banned knowledge is almost certain to spread. Again, the Com-

missioners urge that warning lectures should be given in factories and workshops, but though the lecturers may carefully avoid this subject, they are certain to be questioned about it by individuals after the lecture. According to Prof. Blaschko's evidence, the German Society for the Prevention of Venereal Diseases has found itself obliged to include prophylactic measures in the instruction given to adult men, and it is possible that lecturers in this country might by force of circumstances be compelled to take the same course.

PROSTITUTION AND SYPHILIS.

Many facts of great interest are brought out in these volumes, but space precludes more than a cursory examination of a few of them. The Commissioners were quite unable to find out where habitual prostitutes obtain treatment for venereal diseases. The medical officers of lock hospitals, general hospitals and infirmaries were all closely questioned, but in every case they stated that prostitutes only formed a very small proportion of their patients. It is difficult to believe that these women do not get treated, for we should probably then see many more neglected cases about: nor is there any reason to believe that they go in large numbers to quacks. The view may be put forward that the "professional" prostitutes are really much freer from active syphilis than is generally supposed. The great reservoir of this disease among women is probably the class of girls engaged in shops and other occupations, kept women, and others who might be termed "amateurs." These become infected while young, and when they drift into the regular ranks have largely recovered from the active and infecting stages of the disease. Continental experience shows that venereal diseases are mainly spread by the young clandestine prostitutes.

HOUSING AND VENEREAL DISEASE.

In their general conclusion the Commissioners say, "We are also conscious of the fact that overcrowded and insanitary dwellings indirectly contribute to the spread of venereal disease, and from improvements in this direction, we should expect some diminution of its prevalence." This is an interesting statement in view of the attitude and action of the police authorities towards prostitutes, which tends everywhere to drive them into the poorest quarters of the towns. Strong evidence to this effect was given as regards Dublin, by Dr. Meldon, representing the Royal Colleges and Universities of Ireland. He said "What has happened of recent years is that these poor, unfortunate women have been driven from pillar to post. Wherever they get a resting place, they are driven on, and the consequence is that they are now in the worst insanitary condition. They are practically living in any of the houses that will probably be condemned in a few weeks' time, and they are then driven from that to another, and they have no means of keeping themselves clean. . . A woman who has no chance of keeping herself clean very soon loses any shred of self-respect she has." Here, our social arrangements seem to have led to a vicious circle. In the interests of morality, we drive the women into the very quarters where, in the interests of health, they are least to be desired.

INCIDENCE OF THE COST OF TREATMENT.

The Commissioners propose that free treatment for venereal diseases should be made available for all classes of the community, and that of the cost thereof, 75 per cent. should be met by imperial grants, 25 per cent. being raised locally. But it is clearly established that the incidence of venereal disease is very much higher in urban than in rural districts, hence the effect of paying 75 per cent. of the cost out of general taxation would be to impose

an unfair burden upon rural districts. In the case of Ireland, for instance, it would mean that all the rural part of the country which is extraordinarily free from venereal disease would pay for the sickness in Dublin and Belfast. There are several Acts under which we practically penalise healthy villages for the benefit of unhealthy towns. Sometimes this is justifiable, but it seems to me that in regard to venereal diseases a very strong case exists for requiring all the cost of treatment to be borne locally.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

IS GONORRHOEA A BLOOD DISEASE?

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Royal Commission's Report on Venereal Diseases contains much illuminating matter, but it sets forth a couple of statements which will excite controversy.

It concludes that gonorrhœa, though a local disease at its inception, becomes, at least when long continued, a blood disease. Toxins are assumed to be absorbed into the blood from the gonococci, and, circulating therein, to give rise to a species of purulent polyarthritis, or gonorrhœal rheumatism. A further manifestation is a species of backache, or lumbago, due to the absorption of the toxins, which are supposed to affect the fibrous tissues of the back.

It seems to me that affections of the joints, and of the back, subsequent to gonorrhœa, have become more prevalent of late years. It is the fashion to ascribe every disease of whose ætiology we are ignorant either to a micro-organism or, if that cannot be found locally, to the toxin derived from it. Still, gonorrhœa has hitherto been held to be a strictly local disease, and one is not prepared to give up a favourite superstition without a protest.

The Report makes light of the chancroid sore, stating that the serious ones are generally the result of mixed infection. This is partly true, but one has seen undoubted chancroid followed by suppurating bubo which racked the patient with pain and exhausted him physically and financially, leaving him a helpless wreck in bed for weeks, and not a man but a malady—a huge suppurating sore for months after—and still no sign of syphilis. In fact, one often sees far more disablement and pain from chancroid than from either syphilis or gonorrhœa.

I am, Sir, yours truly,
J. C. McWALTER, M.D., F.R.F.P.S.

Dublin.

VENEREAL DISEASE AND DIVORCE LAW REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The final report of the Royal Commission on Venereal Diseases is now before the public, and perhaps nothing in it is more significant than that it confirms and endorses the recommendations of the late Royal Commission on Marriage and Divorce on this subject. The more the social sores come under examination, the more evident it becomes how intimate is the connection between them and the present marriage and divorce laws, and how urgent is the need for their reform. This reform, so long overdue, cannot with safety to the nation be longer delayed, when we consider the many

thousands of married women suffering from this terrible scourge, who, believing that they have no remedy, suffer untold agonies in secret, and go on producing tainted children, or are sterilised. The common mistake is too often made that women neither know nor think of these things. With the higher education, wider reading, and the growth and power of the woman's movement, women have come to look upon this question as one of the supremest importance to them, their offspring and the race, and it is good to see that a body of men and women have at last made definite and strong pronouncements, which cannot be ignored.

Perhaps now that the country needs new life, the British people will insist that their representatives in Parliament shall set about safeguarding the nation by making venereal disease a ground for divorce.

I am, Sir, yours truly,
MAY L. SEATON-TIEDEMAN,
Secretary.

Divorce Law Reform Union,
19 Buckingham Street,
Strand, W.C.

INFANTILE MORTALITY: THE POPULATION QUESTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your excellent editorial paragraphs, together with Dr. Fothergill's suggestive letter, serve to keep this question to the front. It has been discussed fully in your editorial and correspondence columns on many occasions during the past thirty years. It has now gained wider consideration than ever before in consequence of the exposure of fundamental facts by the present war. Never before has there been made so glaringly visible the fact that these islands in the matter of population must be looked upon as the motherland of our vast empire; and never before has there been so clearly exposed the false position of the band of zealots or fanatics who have in late years gone about preaching the doctrine that restriction of population is the one sole remedy for most of our graver social maladies. These people have taught virtually that these islands form tight compartments from which no overflow of population is possible and that therefore it becomes merely a question of time when want and famine shall result from the overcrowding. They have not been able to recognise the extent of our vast Dominions and Colonies, which, not to speak of India and Burma, contain lands with untouched virgin resources suitable for British settlers in extent as great as three Europes. They forget that vast areas of sub-tropical and tropical lands have, thanks to medical science, now been made habitable by Europeans, and where, as, for example, throughout Central Africa there exist table-lands and hill-country, the climates are the most splendid in the world. These remarks apply to the lovely islands in the West Indies and those in the Pacific, some of which latter of great size we have lately taken from the Germans. We have also just taken German S.W. Africa, and there can be no doubt that German E. Africa is now falling into our hands. Besides these additions to our Dominions we shall probably have a share of the Cameroons and the other forfeited German colonies—lands in extent equal to two or three times the British Islands. It is evident that if extensive infantile mortality could be put an end to—as it surely can be—if the general death-rate could be further decreased; if the marriage-rate were to be increased, and if no undue restriction of the family were practised, there would still be room within our Empire for the whole of our surplus during at least some

hundreds of years. Our Dominions and Colonies are crying out for population, and there can be no doubt that one result of the closer union of the Empire, which this war is bringing about, will lead to the formation of an Imperial system of emigration, through which our increase will be distributed throughout the lands where they are most needed and paternally guarded there till established. The task before us at home is to raise the level of our lower strata so that they may be physically and ethically fit to act their part as empire builders. Science has now given to mankind the power to mould as they please their physical, moral and ethical future; but it must be true science, and the science must be directed by leaders inspired by true morality and really high ideals. Germany is showing us what is the result of science applied to national development when unguided by true morality. The end of the war is coming; a small ray of light is now visible on the dark horizon, which must slowly or quickly widen out until the sky becomes fully illumined by the dawn of peace. In the work of social regeneration, the fruits of which can alone offer any compensation for the vast mass of human anguish and misery which the war has inflicted, the medical profession will have the opportunity of taking the lead—they will not surely fail in this duty.

I am, Sir, yours truly,
A STUDENT OF SOCIOLOGY.

March 11th.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN
IRELAND.

SECTION OF MEDICINE

MEETING HELD FRIDAY, FEBRUARY 4TH, 1916.

The President, JAMES A. LINDSAY, M.D., F.R.C.P.,
in the Chair.

EXHIBITS.

CASE FOR DIAGNOSIS.

DR. NESBITT exhibited a young man who had complained for the past eight or nine months of increasing shortness of breath on exertion and swelling of the abdomen. A large, painless, and non-tender mass was found, apparently connected with the liver, irregularly rounded and semi-elastic, giving no percussion thrill, and moving freely with respiration. There was considerable cyanosis and venous congestion of the face (but not of the arms), which were much aggravated by stooping. On X-ray examination a very broad heart shadow was revealed, with masses about the root of the lung, and some evidence of scattered pulmonary fibrosis. The urine and blood were normal; Wassermann test negative. The difficulty in diagnosis lay mainly in trying to group such diverse findings under one heading. He considered the liver condition either hydatid cyst or a large angioma, and was forced to conclude that the pressure signs in the thorax were due to some independent factor—*e.g.*, mediastinal glands.

ACUTE GENERAL TUBERCULOSIS, WITH LEFT OCULO-MOTOR PARALYSIS, AFTER MEASLES.

Sir JOHN MOORE reported the case of a little girl, aged four and a half years, who had measles nine weeks before her admission to the Meath Hospital on January 5th, 1916. Her attack was followed by "broncho-pneumonia," and suddenly and finally by complete paralysis of the left oculo-motor nerve.

On admission, the axillary temperature was 96° F., the pulse rate 86, and the respirations 28 per minute. The child was conscious and intelligent. She answered questions more by gestures than by speech. Her tongue was thickly coated. There was complete paralysis of the left third nerve. The fourth and sixth nerves seemed to be unimpaired in power and function. Dr. Euphan Maxwell examined the child's eyes on Saturday, January 8th, and again some two days later. Her report ran as follows:—

"O.D.—Pupil dilated and immobile; muscular movements apparently normal (external).

"O.S.—Complete third nerve paralysis.

"Ophthalmoscopic Examination:—O.D.—Chorioid very thin; disc apparently normal, except for some congestion of the inferior veins.

"Examination of the left fundus:—Disc somewhat pale. I could detect no congestion. Isolated patches of chorioiditis. Chorioid very thin as in O.D."

Dr. Maxwell suggested congenital syphilis as a possible cause of the condition, but there was no history to point in such a direction, and the diagnosis, already arrived at, of tuberculosis, was adhered to. The child's strength failed rapidly. Vomiting set in, and finally complete unconsciousness ended in death on January 15th. Dr. Brontë, pathologist to the hospital, furnished the following note as to the *post mortem* findings:—
"Disseminated tuberculosis of both lungs and also of the mediastinal glands. Very profuse tuberculosis of the pericardium, diaphragm, liver, kidneys, spleen, and peritoneum. Extensive basal meningitis."

The question as to the exact cause of the pronounced left oculo-motor paralysis must remain unsolved. After hardening, a detailed histological examination of the nucleus of each third nerve was made by Dr. Brontë, but no evidence of direct tuberculous mischief was forthcoming at that point or in the intra-cranial course of either oculo-motor nerve. As the left eyeball was not removed, it was not possible to state what was the condition of the corresponding oculo-motor nerve in the orbit, or within the area of its final distribution.

Dr. LITTLE thought that the child was probably on the eve of a tuberculous outbreak before she contracted measles. In his early experiments with guinea-pigs he had noticed an invariable infection of the bronchial and mediastinal glands in the animals which died of tuberculosis, and he had constantly observed the same association in autopsies on cases of tuberculous meningitis.

Dr. EUPHAN MAXWELL said that the signs in the left eye—namely, complete third nerve paralysis and commencing optic atrophy—were obviously due to the pressure of the exudate at the base of the brain. The patches of chorioidal atrophy in the left eye probably marked the site of previous metastatic tuberculous inflammations. The thinning of the chorioid in both eyes was possibly a congenital abnormality, and had no bearing on the case. The signs in the right eye—namely, internal third nerve paralysis and slight congestion of the inferior veins at the disc margin—were probably also due to basal pressure. Although theoretically the involvement alone of this small portion of the third nerve, in which also ran the fibres to the inferior oblique, seemed strange, it would seem that clinically it was not uncommon.

NOTES OF A CASE OF CHYLURIA.

The PRESIDENT read notes of a case of the above, for which see MEDICAL PRESS AND CIRCULAR, March 1st, p. 192.

Dr. WALTER SMITH said this condition was one of the rarities as well as mysteries of medicine. He showed a specimen of urine which he had had in his possession for a number of years, and which still retained its original characters. Fat in the urine in minute quantities was a common occurrence—*e.g.*, fatty casts. Lipuria was also common in certain animals, such as the dog and cat. There was, however, no real connection between lipuria and chyluria. In chyluria the fat was present in a very fine emulsion, and the condition was independent of diet. It had been observed in very diverse conditions—for example, pregnancy and cancer of the stomach. In lipuria the fat occurred in more massive form, and did not remain in emulsion. Lipuria had been found in obesity, diabetes, hæmatoporphyria, etc. A third very interesting form in which fat might be found was as liquid crystals, which could be differentiated only by means of polarised light.

Dr. PEACOCKE referred to a case of lipuria formerly under his care, in which the condition seemed to have been brought about by taking a preparation of liquid paraffin. When this drug was stopped the lipuria ceased, but started again when it was resumed.

Dr. BEWLEY said he had a case of chyluria some years before in which the urine was exactly similar to the specimen shown. On some occasions the urine solidified into a jelly in the vessel in which it was placed. He had found all forms of treatment quite useless.

Dr. ROWLETTE mentioned a case the urine of which he had examined on several occasions at the Rotunda Hospital. The patient was a negress who had never been abroad. She was in good health otherwise.

The PRESIDENT, in reply, said he thought it a mistake to give a fatty diet, as had been recommended in several text-books. His patient was a strong, vigorous man, and he advised abstention from fat and reduction of exercise.

old Teachers and Master Apothecaries, or anybody else.

Likewise, to do all that in my power lies to increase the honour, glory and majesty of Medicine.

Likewise, never to divulge the secrets and mysteries of Medicine to idiots and unworthy persons.

Likewise, never to undertake anything rashly without the advice of a Physician, or for filthy lucre.

Likewise, never to administer purgative remedies to patients suffering from acute maladies without first seeking counsel from some learned Physician.

Likewise, never to uncover the sexual organs of a female unless it be absolutely necessary, that is, for the application of remedies.

Likewise, never to betray any secrets which may have been confided to me.

Likewise, never to administer poison to anyone, nor to advise anyone to have recourse to it, even for their greatest enemies.

Likewise, never to administer any abortive potion.

Likewise, never to attempt the removal of the fruit of the womb, except by order of a Physician.

Likewise, to execute faithfully "secundum artem" all prescriptions of Physicians without adding or subtracting anything.

Likewise, never to substitute any drug without first consulting some wiser person than myself.

Likewise to disown and to shun like the plague the scandalous and totally pernicious practice of empirical charlatans and alchemists, who carry on their trade to the greater shame of the magistrates who allow them to do so.

Likewise, to always give aid and succour to such as need my services.

And, finally, never to keep worthless and obsolete drugs in my shop.

May the Lord continue to bless me as long as I observe these things.

SPECIAL REPORTS.

MEDICAL ANTIQUITIES.

DR. DORVEAUX has lately published in the "Bulletin des Sciences Pharmacologiques" an interesting account of the *Oath of the Christian Apothecaries, fearing God*, which has been compared to the "Hippocratic Oath" of physicians.

This oath was supposed to have been first used in the reign of Philippe de Valois in 1336, but Mr. Dorveaux shows that it was composed in 1608 by Jean de Renon, Counsellor and Physician to the King. It is naturally couched in old French, and the following is its equivalent in modern English:

"Oath of the Christian Apothecaries, fearing God."

I swear and promise before God, Author and Creator of all things, Unique in Essence and distinguished in Three Persons, everlastingly blessed, to observe in every point the following articles:

And first I swear and promise to live and die in the Christian Faith.

Likewise to love and honour my father and mother to the best of my ability.

Likewise to honour, respect and render service as far as I am able to do, not only to Doctors and Physicians who have taught me the knowledge and precepts of Pharmacy, but also to my Preceptors and Master Apothecaries, under whom I have learnt my profession.

Likewise, never to speak disparagingly of my

TORQUAY AS A HEALTH RESORT.

TORQUAY, from its situation, is eminently suited for the cure of invalids; being built on a series of hills overlooking the sea, it is possible to get almost any aspect suitable to individual cases. Owing to its situation it enjoys probably the most equable temperature in England. With a mean winter temperature of 44.7° and a mean summer temperature of 55.7°, it will be found to average higher in the winter and lower in the summer than almost any health resort in this country. In 1912 the meteorological report issued by the Borough of Torquay gives a maximum and minimum mean temperature for January at 44.2°, and for August 57.2°; whilst the maximum shade temperature on the hottest day for twenty-five years up to 1909 was 79.0°, which has only been exceeded twice since: the maximum at highest being 83°, at a time when there were several resorts in England with a maximum of 97° and 100°.

Summer visitors are often astonished to find Torquay much cooler than their homes in Yorkshire and the midlands. From the foregoing it will be seen that from its temperature Torquay should be classed as a summer as well as a winter resort. It has for many years been popular as a winter resort, and has a great reputation in the treatment of lung disease, in chronic bronchitis, in invalids recovering from acute lung disease, and in a large number of patients with early phthisis the cure of these conditions being due to the equable temperature, the excellent drainage due to the limestone soil and

the slopes of the hills, both conducive to rapid drying of the streets after the heaviest rainfall.

The invalid is better catered for than in past years. Not only has the hotel accommodation increased, but there are more amusements. The Pavilion, opened a few years ago, is supplied with an excellent orchestra, and the programme of music is of the best. Motors have made it easy to visit the numberless beauty spots on Dartmoor and neighbourhood.

Within a very short period the Torquay Council will have opened their new bathing establishment, which will provide a variety of invalid baths and a large sea-water swimming bath. There is also already in the town provision for those invalids requiring different forms of electrical treatment.

The water supply of the town is excellent. It is probably unequalled for softness and freedom from contamination of any sort; any invalid who wishes for a water free from calcium salts cannot do better than drink it at Torquay.

Patients who require a bracing climate will find a great difference in Babbacombe, which is only a mile from Torquay. It is placed high on the cliff with a N.E. exposure, looking out as it does on the Exmouth to Portland coast. A decided asset to this health resort is the splendid service of express trains run on the Great Western system, whereby the 200 miles journey from or to London are run in four hours; equally fast services being maintained from the Midlands, Yorkshire, etc., via Exeter.

OBITUARY.

Dr. R. D. MAXWELL, M.D., F.R.C.S., LONDON.

The death occurred on March 6th, after an abdominal operation, of Dr. Richard Drummond Maxwell, assistant obstetric physician to the London Hospital. He traced his descent from an old Scottish border family. He had a strong regard for Scotland's ancient ally, France, and he always evinced interest in military matters. Educated at the London Hospital, he graduated M.B. London in 1897 and M.D. in 1904. In 1907 he took the F.R.C.S. Eng. In the S. African War he acted as civil surgeon. He was elected physician to Queen Charlotte's Lying-in Hospital, and later became assistant obstetric physician at his old hospital, where he was also lecturer on midwifery to nurses. He wrote largely on his speciality and edited the new edition of "Diseases of Women," originally written by his old chief, the late Dr. Herman.

A man of great ability, Maxwell has died while practically only on the threshold of a great career. He was deservedly popular with his colleagues and students, and will be deeply regretted by a wide circle of friends.

SURGEON-GENERAL LANDALE, M.D.,
L.R.C.S. Edin.

As the result of an accident, Deputy Surgeon-General James Landale has died at Dunboyne, Cheltenham, in his 80th year. While on his way home, General Landale was misled by the darkness into entering the gateway of the house next to his own. In endeavouring to retrace his steps, he fell, and was later found by his wife lying on the public footway. He was apparently uninjured and seemed to recover from the shock, but passed away during the night.

General Landale qualified M.D., L.R.C.S. Edin. in 1856. He entered the army in 1857, served in the Indian Mutiny campaign as officer in charge of medical quarters of the 90th Foot. He retired in 1890. He leaves two sons, both officers in the Indian Army, and now serving in Mesopotamia.

MR. HIGHTWAY JONES, of Salop, left £100 to the Salop Infirmary.

REVIEWS OF BOOKS.

SLEEPING SICKNESS IN THE ISLAND OF PRINCIPE. (a)

THE significance of this well-produced volume does not lie merely in its narrative, although this is of great interest. As will be seen from a "Translator's Note" enclosed as a leaflet (its importance demands that in any future edition of the book it should be included as a foreword), the book is really a plea for justice to Portugal. Colonel Wyllie, the translator, in a statement possessing a brevity and lucidity not always present in military despatches, relates how the Teutonic tentacle nearly closed round Principe. The story, which sheds a new light on the Congo Reform question and the agitation over the San Thomé slavery, cannot be reproduced here; but could Shakespeare's Antonio have beheld Germany, stained with a record of ill-treatment of natives "quite as ruthless in brutality as anything established against the Belgian Congo régime," tenderly pleading the cause of the alleged ill-governed inhabitants of San Thomé and Principe, he would have assured Bassanio with a still stronger conviction that "the devil can cite Scripture for his purpose," and would have exclaimed yet more bitterly, "O, what a goodly outside falsehood hath!"

As we read this "Record of Four Years' War against Sleeping Sickness in the Island of Principe," and discern between its lines the skill, pertinacity, endurance, and devotion of the four men waging the warfare, we cannot avoid the feeling that the present world-struggle would be further advanced had our cause been marked by the same admirable adaptation of means towards ends, the same grasp of situation, and, the British taxpayer will ruefully add, the same economy.

Thanks to the translator, who adds to clear diction a system of cross-heading and paragraphing that makes the narrative more readable than an ordinary novel, we are carried step by step through the campaign with never-flagging interest. The sanitary history of the Island (herein we read that some 25 per cent. of the total population was found to be infected with the trypanosomes in the period 1907-1911; this fact alone indicates something of the task which confronted the dauntless four); its physical characteristics with the flora and fauna; the Glossina; the War and its Results; the Sanitary Future of the Island—all are fully treated of, yet never tediously, and the book concludes with a detailed study of the trypanosomes, etc., concerned. As an example of the ingenuity employed, reference may be made—considerations of space alone prevent many other such references—to page 103, "Use of a Viscid Paste to Trap the Fly," a story not without an element of humour. This paste was spread on a cloth of dark colour and worn on the backs of a certain number of contracted labourers, the glossinæ settling freely on the paste. So much did this contribute to the eradication of the fly, that we find that whereas in 1911 nearly 204,000 were trapped by this means, the number of flies on the island in 1914 had so decreased that only 34 were caught, although the number of catchers employed had risen. All this was but one phase of the activity of the "Official Sanitary Brigade," organised in 1911, and at first composed of 43 men only, "all prisoners of war and delinquents sentenced to penal servitude"! Even up to March, 1913, the strength was only 100, increasing to an average of 300 from February, 1914. Other steps were the clearing of jungles, the draining of swamps, the extermination of fauna harbouring the trypanosomes or even "suspect" of doing so (even 2,000 civet cats being done to death, although no evidence existed that they were guilty of being carriers), the killing of all infected animals, and the injection of atoxyl into all infected inhabitants until repeated examinations showed the absence of trypanosomes from the blood. Thus did our Ally translate into action Mr. Kipling's "Song of the English":

(a) "Sleeping Sickness in the Island of Principe." Pp. xii, 260; plates, 70 plain and 5 coloured; 3 coloured maps. Royal 8vo. London: Baillière, Tindall and Cox. 1916. 7s. 6d. net.

"Keep ye the Law—be swift in all obedience—
Clear the land of evil; drive the road and bridge
the ford.

Make ye sure to each his own,
That he reap where he hath sown."

Indeed, this last line may be quoted with special aptness, considering the bearing of all this work upon the agriculture of the island, so severely threatened by the malady fought against. From page 123, we find that Portugal, whose reputation has been so industriously blackened by her huge enemy, spent in one half-year alone (1914) nearly \$157,000—say, over £36,000, in this righteous war. Severely restrained though the tone of the narrative is, we cannot but think that the authors must have begun the third part with the heading of the first section as "Disappearance of the Glossina from the Island," with a touch of entirely justifiable pride.

The translation, as we have said, is most easy reading, although on page 5 the translator speaks of the "autochthonous" population; surely "aboriginal" would serve. English readers would have been grateful to him if he had, at some little trouble, translated the foreign measures, etc. It is difficult to think in terms of hectolares, kilometres, and degrees Centigrade. This has evidently occurred to him, for he converts in one place a sum of Escudos into English money. On the other hand, an excellent glossary is prefixed. It would also have been very serviceable if the coloured plates and maps at the end had been bound in with blank inner leaves, to allow of pulling out for reference when reading the pages to which they refer, while the magnification has not been stated in the trypanosome plates.

The 70 photographs are beautifully printed; we do not remember to have seen photographs so well reproduced on paper which is not sized or glazed: the various landscapes, etc., are a continual artistic delight. We cannot conclude without making mention in honour of the four leaders in the war, whose successful labours are recorded: Drs. B. F. Bruto da Costa, J. F. Sant' Anna, A. C. dos Santos, and M. G. de Araujo Alvares.

PHARMACOLOGY. (a)

WE are reminded in the preface to the sixth edition of this comprehensive text-book on the action of drugs in health and disease that "the insistence on numberless preparations of drugs of questionable value has discouraged interest in therapeutics." It is, of course, true that even the new "British Pharmacopœia" contains several remedies that are comparatively seldom used by medical practitioners, whereas other old friends are not to be found within its pages. Nevertheless, the individual prescriber will still continue to be influenced in his choice of drugs by experimental work and by careful observation and comparison of the experiences of investigators in the field of pharmacology. In deciding what remedy shall or shall not be retained in any official list much depends upon the degree of success that has been obtained with it in the hands of those responsible for the compilation of such a schedule. Indeed, the personal factor enters largely into our prescribing, and, whether we choose to admit it or not, into our therapeutics as well. On these grounds it is difficult to criticise any work that professes to deal in an unbiased manner with the study of pharmacology. It would be better, therefore, to risk a little extra bulkiness of volume rather than exclude all mention of many drugs which have proved themselves useful in the hands of practising physicians. We should have expected in this edition to have found some account of the recent work in connection with the antiseptic action of hypochlorous acid, of the effects of chlorine gas when inhaled—as illustrated by numberless cases that have recently occurred among soldiers—of the "twilight sleep" produced by the administration of scopolamine, while we also look in

(a) "A Text Book of Pharmacology and Therapeutics." By Arthur R. Cushny, M.A., M.D., LL.D., F.R.S., Professor of Pharmacology in the University of London, etc. Sixth edition, thoroughly revised. With 70 engravings. Pp. X., 703. London: J. and A. Churchill, 1915. Price 15s. net.

vain for any mention of leeches, garlic, scarlet-red, the non-staining preparations of iodine, or casein as an ointment-basis. Much more might have been said about chaulmoogra oil, which is dismissed in four lines. We note that the use of the glycerophosphates is stated on p. 684 to be nil; yet these salts enter largely into many of the so-called reconstructive nerve-tonics and foods, and are prescribed largely by the profession. A description of the dermatitis from plants strikes us as being hardly relevant to a work on therapeutics. The use of carbon dioxide snow in the treatment of nævi does not appear to be mentioned, only a general statement occurs on p. 79. A good deal of space is devoted to such theoretical considerations as lime starvation of the tissues, the action of nicotine, the nature of counter-irritation, and the effects of the various animal extracts upon the circulatory and other systems. The book teems with German references, but we note that it was "printed in America." As the work of a scholar and a sound teacher it may be safely commended to the notice of senior students and practitioners who desire to possess a good standard text book of pharmacology and therapeutics.

MANUALS FOR NURSES (a).

WE have received three very useful books which may be recommended to nurses. Miss Pope's work on *Anatomy and Physiology* gives an excellent *résumé* of these two subjects in simple language. The illustrations, some of which are in colour, form a special feature of this really delightful volume. The "Quiz-Book of Nursing" should be in great demand with nurses desirous of revising their knowledge prior to examinations. The writers of these two books are nurses of great experience as lecturers on the subjects with which they deal, accordingly we find their work is thorough, practical and helpful. They give just the kind of information which the nurse requires to know during her period of training. The "Handbook of Massage" is written specially for those who are beginning to study the subject. It is, therefore, distinctly elementary in its scope, and is largely based on the author's well-known text-book. Besides chapters dealing with various forms of massage in a variety of diseases, there is one on its use in cases of bullet and shrapnel wounds, frost-bite, and traumatic neurasthenia. A useful account of medical electricity is also given at the end of the volume. The book is very fully illustrated by some ninety figures in the text. It may safely be recommended to nurses and others desirous of knowing something about this useful therapeutic aid.

APPLETON'S MEDICAL DICTIONARY. (b)

WE wonder why the medical dictionaries found in most consulting rooms are of American origin. Surely the countrymen of Dr. Johnson can hold their own at dictionary-making with Webster's compatriots. The rapid development of medical science involves a steady growth in terminology, and we confess to the need of frequently consulting a medical dictionary. The work under review appears thoroughly up to date, though it is well remarked—what must be the case with such a volume—"it is impossible that the matter of this book should be fixed and perfected." The book contains an appendix of over 50 pages which should prove very useful. The List of Undesirable Terms framed by the American Medical Association is of value to every medical man, whilst Prof. Warren's article on "Analyses of Body Fluids," gives, in condensed, yet readable form, sufficient matter to fill a text-book.

The type is clear and easy to read. The book is bound in flexible leather, and will form a very useful addition to the professional bookshelf.

(a) "Anatomy and Physiology for Nurses." By Amy Elizabeth Pope. Second edition, revised and enlarged. \$1.75. New York and London: G. P. Putnam's Sons, 1915. "A Quiz-Book of Nursing." By Amy E. Pope and T. A. Pope. Second edition, revised and enlarged. \$1.75. New York and London: G. P. Putnam's Sons, 1915. "Handbook of Massage for Beginners." By L. L. Despard. London: Henry Frowde and Hodder and Stoughton, 1915.

(b) "Appleton's Medical Dictionary." Pp. 945. New York and London: D. Appleton and Co. Price 15s. net.

LITERARY NOTES.

A NEW volume entitled "More Minor Horrors," by Dr. A. E. Shipley, is now in the press, and will be published by Messrs. Smith, Elder and Co. in the early spring. It is, in a sense, a sequel to the "Minor Horrors of War," a third edition of which is now in course of preparation.

* * *

FROM *The Prescriber* offices, Edinburgh, comes a shilling booklet by Mr. Thos. Stephenson, entitled "Incompatibility in Prescriptions and How to Avoid It." It gives a very good account of this important and practical subject, which is apt to be greatly neglected in these days. It ought to be carefully studied and its teaching borne in mind by every practitioner of the healing art.

* * *

THOSE interested in the surgical advances made in the war will welcome a *résumé* of the subject. "Surgery in War," by Major A. J. Hull, F.R.C.S., R.A.M.C., is an attempt in this direction. Sir Alfred Keogh, K.C.B., has written the Preface, and Lieut.-Col. E. M. Pilcher, D.S.O., the Introduction. Numerous X-ray plates and diagrams elucidate the text. The book will be published immediately by Messrs. J. and A. Churchill.

* * *

THE announcement that Dr. W. Blair Bell, Gynæcologist to the Liverpool Royal Infirmary, will shortly publish through Messrs. Baillière, Tindall and Cox an original work, with 50 plates, coloured and plain, on "The Sex Complex," has excited considerable interest, it being the first definite attempt to deal systematically with the subject. The same firm have just issued the 4th and final part of Mr. Jackson Clarke's work on "Protozoa and Disease." This new part is specially devoted to *Rhizopod Protozoa*, and is a complete monograph in itself; the author's investigations and observations on the origin and causes of cancer will be found most interesting.

* * *

THOSE who are lured by its attractive title to a perusal of Dorothy Cator's "In a French Military Hospital" (By Dorothy Cator. London: Longmans, Green and Co. Price, 2s. 6d. net.), are condemned to serious disillusionment. From considerable experience in France during the present war, of such hospitals and personnel as she describes, we are led to quite contrary conclusions, and would suggest that a wider knowledge of the hospital work abroad would have prevented the impulsive and untrained authoress from rushing to record in print her hastily formed impressions. The slipshod English of these 99 pages is probably the style most suitable to the matter—hurried notes full of trivial personalities and criticism—which we sincerely trust may never reach the eyes of our gallant allies.

* * *

WE have received the "Wellcome Photographic Exposure Record and Diary, 1916." This little volume maintains its reputation as a concise encyclopædia of photographic information, ranging from simple routine operations to the developments of the higher photography.

It informs and advises on photography by night and the correct quantities of flashlight powder; on green, or sepia, or blue toning of bromides, or warm tones on gaslight papers; on time and factorial development, the intensification of colour plates, exposures for interiors, the speeds of bromide papers, the staining of prints, etc., etc. Not one of the varied aspects of the art appears untouched, and besides all this there are instructive tables, simple formulæ and a multitude of useful hints.

The illustrations have always been a feature of this publication.

This year the photographs reproduced are of more than usual interest.

The meeting of H.M. King George V. with the King of the Belgians in Flanders, as recorded by the camera of Mr. J. Wilson Parker, will be appre-

ciated both for its high quality and its historic interest, as also will the fine example of the photographic work achieved on Sir Douglas Mawson's Antarctic Expedition; while nothing could be finer than the two photographs of actual fighting in the Dardanelles, by Mr. Ernest Brooks, the official photographer to the Expeditionary Forces.

Of the "Wellcome" Photographic Exposure Record and Diary, three editions are published—for the Northern hemisphere, the Southern hemisphere, and for the United States of America.

The "Wellcome" Exposure Record can be obtained from all photographic dealers and booksellers. Price in the British Isles, one shilling.

MEDICAL NEWS IN BRIEF.

King and Queen at Star and Garter Home.

THE King and Queen visited the Star and Garter Hospital for Disabled Soldiers at Richmond on March 9th. They were received by Sir Frederick Treves and Lord Farquhar, and Major J. L. Dickie, R.A.M.C., the medical superintendent, and Miss Lawrence, the matron, were presented to Their Majesties. There are at present 36 soldiers in the home, and the King and Queen, who made a thorough tour of the hospital buildings, visited each ward and spoke to each patient. Their visit lasted over an hour.

Sir W. Hartley's Gifts to Hospitals.

SIR WILLIAM P. HARTLEY in remembrance of his seventieth birthday, and in recognition of his debt to the public, has decided to transfer £15,000 of his Four and a Half per Cent. War Loan to twenty-two London and Liverpool hospitals, £10,000 of this would be transferred to London hospitals, the remaining £5,000 to Liverpool hospitals.

The London hospitals benefited are:—Bermondsey Medical Mission and Surrey Dispensary, £100 each; Queen's Children's (Hackney) and Throat and Ear Hospital (Golden Square), £150 each; Evelina Children's Hospital, Metropolitan Hospital, London Homœopathic Hospital, General Lying-in Hospital, Royal Eye Hospital, Cancer Hospital, Consumption Hospital, Brompton, £250 each; St. George's Hospital, Waterloo Hospital, Charing Cross Hospital, Westminster Hospital, London Temperance Hospital, St. Thomas's Hospital, £500 each; Royal Free Hospital, £750; King's College Hospital, Middlesex Hospital, Guy's Hospital, London Hospital, £1,000 each.

Surgical Operations at the Front.

IN a Parliamentary answer on the subject of abdominal operations at the front, Mr. Tennant says:—"The arrangements in France have the full approval of the consulting surgeons and of others most competent to judge. I have quite recently received a report from Sir Frederick Treves in which he states that in many cases a man in need of a grave operation has found himself on the operating table within three or four hours of his being shot, and that he was informed of cases in which operations upon the skull and the abdomen had been carried out within two-and-a-half hours of the receipt of the wound; and he adds that such prompt attention could not be obtained by a wounded civilian in any rural district in England."

Chester Royal Infirmary.

THE report submitted at the annual meeting of the governors of the Chester Royal Infirmary, held on March 9th, stated that the number of patients treated during last year was 7,804, as compared with 8,067 in 1914. The average cost per head was £73 16s. 5d., against £72 8s. 10d. in the previous year. The total receipts, including £1,221 in legacies, amounted to £8,076 15s. 2d., and the total expenditure to £8,148 18s. 4d., against £6,718 os. 7d. in the previous year.

By arrangement with the war authorities, 140 beds were to be reserved for sick and wounded soldiers.

The total expenditure for the year exceeded the income for the same period by £355 18s. 5d., against £2,378 18s. 2d. for 1914. The overdraft on the revenue account was now £6,312 9s. 2d. The aggregate of the King Edward Memorial Fund was now £39,384 1s. 6d., and the amount due to the contractors was £47,791 9s. 10d.

Two visiting surgeons had joined the R.A.M.C. It was announced that Sir Owen Philipps, M.P. for the city, had sent a cheque for £250 as a donation to the King Edward Memorial Fund for the extension and renovation of the Infirmary.

Medical Science in Shakespeare's Time.

THIS was the subject of a lecture delivered on March 7th to the members of the Dundee Naturalists' Society by Dr. A. H. Millar. The lecture was a sequel to one delivered last session by the doctor on "Natural Science in Shakespeare's Time." Shakespeare, Dr. Millar pointed out, began to write at a time of transition in medical science, when the old empirical system was passing away and writers like Vesalius, Fallopius, Fabricius, and Harvey were revolutionising prevalent ideas as to anatomy and physiology. In a series of quotations from the dramas the lecturer showed how aptly Shakespeare could diagnose the symptoms of a disease, and how he almost anticipated Harvey's great discovery of the circulation of the blood, and certainly suggested trying the effects of drugs upon the lower animals with all the eagerness of a modern vivisectionist. In conclusion, Dr. Millar said the study of this subject served to intensify the mystery that surrounded the myriad-minded Shakespeare.

Dundee Infant Mortality.

At a meeting of the Public Health Committee of Dundee Town Council on March 7th, a suggestion was made that the Medical Officer's annual report on the health of the city (already referred to in our columns), in so far as it dealt with the question of infant mortality, should be remitted to a Committee for consideration, the duty of the Committee being to frame definite recommendations for the consideration of the Town Council.

Reference was made to the seriousness of the problem, and suggested that the subject be discussed at a special meeting of the Town Council. It was proposed that the question should be tackled in a broader way, and that the issues which had been presented by Dr. Templeman fairly and frankly should be taken up by Dundee in conjunction with the larger Corporations in Scotland, and sent to the Local Government Board. While they might carry out something on the lines suggested by Dr. Templeman, he remarked that that was only touching the fringe of the problem.

Bequest to Ramsgate General Hospital.

It was announced at the annual meeting of the Ramsgate General Hospital that Miss J. Stancomb-Wills, who last year gave £1,000 invested in War Loan stock, for the endowment of the "Lord Winterstoke bed," has now presented an Exchequer bond for £1,000 for the endowment of a woman's bed to be named the "Lady Wills of Blagdon."

Lancashire County Medical Officer.

OWING to the continued absence from duty, through illness, of Dr. Sergeant, the county medical officer of health, the Public Health Committee have, in conjunction with the Midwives Act Committee, recommended that Dr. J. J. Butterworth, the school medical superintendent, be appointed to act as temporary assistant county medical officer of health, at a salary at the rate of £200 per annum. "Your committee desire it to be clearly understood that in the event of a permanent assistant county medical officer of health having to be appointed in the future, or of a vacancy occurring in the office of the county

medical officer of health, the temporary appointment now proposed will not confer on Dr. Butterworth any right to be appointed to either of such offices."

Medical Treatment of Leith School Children.

LEITH School Board has decided to obtain the services of a local medical practitioner or practitioners for three hours on two afternoons per week, or two hours on three afternoons per week, to continue the work of medical treatment of school children, as it was carried on by Dr. Walker immediately prior to his leaving Scotland on military service. An amendment, which was defeated by 6 votes to 5, was put forward that the Board should appoint a lady doctor to act as Medical Officer to the Board during Dr. Walker's absence, and to devote her whole time to the Board's medical work.

Doctors' Outstanding Accounts.

At the monthly meeting of the Staffordshire Insurance Committee held at Stafford on March 4th, Dr. Bull referred to a minute of the Medical Benefit Committee, which stated that a letter had been received from a medical practitioner, complaining of delay in settling the amounts owing for 1914, and asked when the doctors might expect a settlement of their accounts for this period. He went on to speak of the hardships of country doctors, amongst these being the increased cost of living, the double cost of petrol, and the increased income-tax. The state of the country practitioner was now really terrible.

The Clerk said that regarding the doctors' accounts, he had just received the necessary information on which to proceed to a settlement, and that work was now going on.

Buxton Military Hospital.

ARRANGEMENTS have been completed at Buxton to convert the Peak Hydro Hotel into a hospital for wounded Canadian soldiers. Over 300 patients are expected, and facilities have been granted to them by the Town Council to have the Buxton waters and treatment, special hours being arranged so that they may not interfere with the general public.

Large Gift to Bristol Infirmary and Hospital.

SIR GEORGE WHITE, presiding at the Bristol Local Infirmary annual meeting on March 7th, announced that it had been arranged, under the will of the late Mr. Francis Cape, of Bristol, that the infirmary and the general hospital should each receive £45,000, free of all charges.

Against L.G.B. Advice.

At a meeting of West Bromwich Guardians on March 6th, the General Purposes Committee reported that they had considered the question of the appointment of a woman assistant medical officer, as suggested by Dr. Fuller of the Local Government Board. They recommended the Board not to fill the position during the continuance of the war. The report was adopted.

Doctor and Petrol Supply.

At a meeting of the Worcestershire Insurance Committee on February 26th, the Chairman said a doctor at Moreton-in-Marsh, who was responsible for the care of patients at Blechley had written stating that a petrol supply company had refused to supply him with petrol, and therefore he hoped the committee would not consider him responsible for the neglect of patients. The Chairman said the committee could not relieve him from his engagement for that reason. The doctor could travel by train, or obtain petrol from another place.

Liverpool Maternity Hospital.

THE Liverpool Maternity Hospital, the annual meeting of which was held on March 6th, is extending its usefulness in a direction which is bound to have important beneficial results. A scheme was foreshadowed for the establishment of maternity centres for ante-natal and pre-maternity work, and for the

opening of a rest home for cases of this character. The report showed that during the year, 1,185 patients were attended in the districts, against 1,301 in the previous year, the services of the district medical officers being called for in 131 cases, and 640 patients were admitted to the hospital, as against 646. The hospital had again been continuously full during the year, and 55 women had been refused admission owing to lack of accommodation. In the School of Midwifery 74 pupil midwives were trained, and 67 were successful in passing the examination. The institution was continuing its work of infant welfare, and there was an average attendance of 60 mothers with their babies at the weekly consultations.

Spectaclemakers and the War.

It has been brought to the notice of the Spectaclemakers' Company that some of its diploma-holders having attested, and being about to join the forces, there is a danger of enforced closing of their businesses. The company is now offering to any nominee of a diploma-holder, free of charges, the services of the official instructor for a course of instruction in optics in London, with a view of his taking his place and continuing his business.

Fewer Suicides in Paris.

SUICIDES in Paris have dropped to about two a week, as compared with an average of fifteen to twenty in ordinary times.

A wag suggests that everyone is so anxious to see off this war will end that they cannot bear to shuffle off this mortal coil until victory crowns the day.

It is just possible that suicides are fewer now because so many favourite means of going to one's long account are not readily available. For instance, from the first moment that war was declared all gunsmith shops were closed up, and neither arms nor munitions of any kind can be bought. No one is allowed on any of the great public monuments, so that jumping off bridges or the Arc de Triomphe is no longer possible.

Asylums Board Economy.

At the meeting of the Metropolitan Asylums Board on March 4th, estimates to meet the expenditure for the half-year ending September 30th, 1916, were adopted which show a reduction of £32,750 compared with the corresponding period of 1915, and involve a rate of 3d. in the pound, or one-eighth of a penny less. The finance committee reported that the decrease is mainly due to three hospitals having been taken over by the military authorities, and to the exercise of the strictest economy in all the Board's institutions.

Father Higley drew the Board's attention to the fact that there were 500 vacant beds in three of the Board's institutions for children, and that there were 229 paid officers for 534 children in these three schools—three officers for every seven children.

British Steel Casques tested in Action.

A report from British Headquarters, France, dated March 6th, states that the new British steel casque has had its first great test in the assault upon the Ypres Bluff on March 2, and the results are more than satisfactory.

The correspondent says: "I was this morning shown a batch of casques from wounded men, which have been collected from the field. In all cases the men who were wearing these were either unscathed or suffering from slight concussion or mere scalp wounds. It is believed that had they not been wearing these helmets they would either have been all killed or dangerously wounded. One of the casques bears an indentation from a heavy blow with the butt-end of a German rifle. The man thus struck bayoneted his assailant and was none the worse for the assault.

Another casque bears distinct evidence of a direct hit with the business-end of a shell. Several of them are rent by fragments of shrapnel casing, manifestly

with the force which against a cloth cap would have been quite sufficient to cause fracture of the bone. Others are pitted by shrapnel bullets. Most of the men who wore these state that except for a rattling like a hail storm sweeping over a galvanised roof, and a sudden compression around the rim of the helmet, they were unaware that they were being struck."

Chinese Decorations for British Doctors.

THE KING has been pleased to give and grant unto the undermentioned gentlemen his Majesty's Royal licence and authority to wear the following decorations which have been conferred upon them by the President of the Republic of China in recognition of valuable services rendered by them:—

Fourth class of the Order of the Excellent Crop: David Duncan Main, Esq., L.R.C.P., L.R.C.S., Church Missionary Society's Hospital, Hangchow.

Fifth Class of the Order of the Excellent Crop: Sidney Gerald Kirkby-Gomes, Esq., Medical Officer, Peking-Mukden Railway, Peking.

A Medical "Conscientious Objector."

A CONSCIENTIOUS objector at Wallesey was the house surgeon of the largest hospital in the borough. His father testified to the sincerity of the applicant's religious convictions, stating that he was converted at the age of twelve at a Torrey and Alexander mission, and had dedicated his life to Christian service. In answer to the Chairman, the surgeon declined to join the R.A.M.C., as that would mean joining the Army, but he said he was delighted to attend to soldiers at the hospital. The Chairman: If we put a label on you and say: "This is a civilian," you would help the wounded. If we put you in khaki, you would not?—That is so. A member of the tribunal told the applicant that his conscience must be very elastic, and that he was evidently prepared to give attention to the wounded so long as he was far enough away from the firing line. Exemption from combatant service granted.

Rheumatism as an "Accident."

JUDGMENTS were delivered in the House of Lords on March 6th, dismissing the appeal of the Glasgow Coal Company (Limited) from a decision of the Second Division of the Court of Session in Scotland on a case stated by the sheriff substitute of Lanarkshire under the Workmen's Compensation Act. The respondent, a workman named Welsh, had been employed in one of the appellants' pits, and when the pit became flooded he was sent to bale out the water. He was engaged in this work for eight hours, standing in the water up to his chest. He afterwards suffered from rheumatism, which prevented him from earning full-rate wages. The sheriff substitute found that the rheumatism was an injury caused by accident arising out of and in the course of the man's employment, and made an award in his favour.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s. post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our official appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice

to the publisher or printer before the type has been distributed. This should be done when returning proofs.

CLINICAL LECTURES, PAPERS, ETC., RECEIVED.

In addition to those announced in our last week's issue as received, the following have also come to hand, and are hereby acknowledged with thanks:—

CHAUFFOND, PROFESSOR, of Paris. "Posterior Friction Sounds, associated with Large Effusion in the Pericarditis of Bright's Disease."

KIRMISSON, PROFESSOR, of Paris. "Inherited Syphilis in the Production of Bone Lesions."

PERSLOW, DR., Birmingham. Clinical lecture on "Extra-Uterine Gestation."

GLADSTONE MEMORIAL AT CHESTER INFIRMARY.

LORD BRYCE will on April 15th open the Gladstone wards of Chester Royal Infirmary, which are to form part of the Hawarden memorial to the late Lieutenant W. G. C. Gladstone, M.P., Royal Welsh Fusiliers, who was killed in action in Flanders in April last year. Lieutenant Gladstone served for a time on Lord Bryce's staff at Washington.

ANTONY (Bedford). Fatal street accidents in the City of London and the Borough of Southwark were 17 more in 1915 than in the previous year.

MAKING ASSURANCE DOUBLY SURE.

OLD LADY: What precaution do you take against water infected by microbes?

Soldier: Well, mum, we boils it—

Old Lady: Yes?

Soldier: The we filters it—

Old Lady: Yes?

Soldier: Then we drinks beer.—*The Bystander.*

R.A.M.C. (Manchester).—The little book recently issued by Capt. Begg, entitled, "The Selection of the Recruit," will probably answer your requirement best. It contains a mass of information for rapid reference for those engaged in the medical examination of recruits.

AN UNREGENERATE LAY.

Froth, a magazine published at the Pennsylvania State College, contains the following:—

Tobacco is a dirty weed,

I like it;

It satisfies no normal need,

I like it;

It makes you thin, it makes you lean;

It takes the hair right off your bean;

It's the worst darn stuff I've ever seen,

I like it.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 15TH.

ROYAL SOCIETY OF MEDICINE (1 Wimpole Street, W.).—*"History of Medicine"* at 5 p.m. Books, MSS., etc., on view at 4.30 p.m.: Mr. R. R. Steele: "A Note on the Scientific Writings of Roger Bacon." Mrs. Charles Singer: *Plague Manuscripts*. Sir William Osler, Bart., F.R.S.: *The MSS. of the Religio Medici*. Captain T. A. Malloch, C.A.M.C.: Sir John Finch and Sir Thomas Baines

ROYAL MICROSCOPICAL SOCIETY (20 Hanover Square, W.).—8 p.m.: Professor J. A. Thomson: *Original Factors in Evolution*. Sir E. Ray Lankester, K.C.B.: *The Supposed Exhibition of Purpose and Intelligence by the Foraminifera*.

THURSDAY, MARCH 16TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF DERMATOLOGY) (1 Wimpole Street, W.).—5 p.m. Exhibition of Cases at 4.30 p.m.: Dr. George Pernet: (1) *Dermatitis Herpetiformis in a Boy*; (2) *Staphylococci in a Girl with Xeroderma (Staph. en nappe et en foyers à progression excentrique)*.

FRIDAY, MARCH 17TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF ELECTRO-THERAPEUTICS) (1 Wimpole Street, W.).—8.30 p.m.: Discussion on Experiments and Experiences with the Coolidge Tube. Opened by Dr. Knox on Experiments with Rotatory and Fixed Tube. Sir James Mackenzie Davidson, Dr. Orton, and Dr. Finzi will also speak. Members wishing to take part in the Discussion will kindly communicate with Dr. Gilbert Scott, 6 Bentinck Street, W.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE (11 Chandos Street, Cavendish Square, W.).—5.30 p.m.: Paper:—Captain H. J. McGrigor, R.A.M.C.: *Some Experiences in the Treatment of Syphilis in the Army, with Special Reference to the Administration of "606" in Concentrated Solutions*. Dr. H. Bayon: *Short Demonstration of Sections and Cultures of Skin Diseases, with some Remarks on the Treatment of Syphilis in African Native Tribes and among the Workers in the Rand Gold Mines*.

Vacancies.

Leeds Public Dispensary.—Lady Resident Medical Officer. Salary £130 per annum, with board, residence, and laundry. Applications, with copies of three recent testimonials, to be addressed to the Secretary of the Faculty Public Dispensary, North Street, Leeds.

The Guest Hospital, Dudley.—Assistant House Surgeon. Salary £120 per annum, with residence, board and washing. Applications to the Secretary.

The Guest Hospital, Dudley.—Senior Resident Medical Officer. Salary £150 per annum, with residence, board and washing. Applications to the Secretary.

The Royal Surrey County Hospital, Guildford.—House Surgeon. Salary £150 per annum, with board, residence, and laundry. Applications to the Secretary.

Bury Infirmary.—Junior House Surgeon. Salary £150 per annum, with board, residence and washing. Applications to the Honorary Secretary, Infirmary, Bury, Lancashire.

Victoria Hospital, Burnley.—House Surgeon. Salary £160 per annum, with residence, board, and washing. Applications to F. A. Hargreaves, Hon. Sec., 7, Grimshaw Street, Burnley.

Downs Sanatorium.—Assistant Medical Officer. Salary £250 per annum, with usual residential allowances. Applications to the Clerk to the Board, Office of the Board, Embankment, E.C.

Cambridgeshire Asylum, Fulbourn, near Cambridge.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, washing and attendance. Applications to the Medical Superintendent.

Nottingham City Asylum.—Senior Assistant Medical Officer. Salary £300 per annum, with apartments, board and laundry. Applications to the Medical Superintendent.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Bishop's Stortford, Herts; Brighouse, Yorks., West Riding.

Births.

BEATTIE.—On March 9th, at 3, Ellison Place, Newcastle-on-Tyne, to Dr. and Mrs. Thomas Beattie, a daughter.

BURTON.—On March 7th, at 13, Prince's Gate, S.W., the wife of Lieut. Hugh Leonard Burton, M.B., R.A.M.C., of a son.

CRAIG.—On March 12th, at 113, Albany Street, Regent's Park, N.W., to Dr. and Mrs. Jas. C. Craig, a daughter.

FRAZER.—On March 8th, at 33, Colville Square, W., the wife of Prof. J. E. Frazer, F.R.C.S., of a son.

HIEBER.—On Jan. 18th, at Leh, Western Himalayas, to Dr. and Mrs. A. G. Hieber, a daughter (prematurely, owing to pneumonia, who survived only three hours).

KING.—On March 6th, at Royal Marine Infirmary, Deal, the wife of Surgeon W. H. King, R.N., of a daughter.

MATHEWSON.—On March 3rd, at "Caradoc," Clun, Shropshire, to Dr. and Mrs. J. W. Mathewson, a son.

PRIDHAM.—On March 5th at Woolston Lodge, Woolston, Hants, the wife of Gerald H. Pridham, M.R.C.S., of a son.

SEQUEIRA.—On March 5th, at Woodburn, South Queensferry, the wife of Fleet-Surgeon W. S. H. Sequeira, R.N., of a daughter.

Marriages.

EAST-MOMBER.—On March 7th, at the Priory Church, Great Malvern, Charles Harry East, M.D., of St. Clare, Malvern, to Mabel, wife of the late Lt.-Colonel Momber, K.O.Y.L.I., of San Remo, Italy.

FENTON-FERGUSON.—On March 7th, at St. Matthias, Earl's Court Square, W. J. Fenton, M.D., F.R.C.P., of 58a, Wimpole Street, W., and L. O. C. Ferguson, only daughter of Major H. and Mrs. Ferguson, of 10, Glazbury Road, Kensington.

HARTRIDGE-WILSON.—On March 7th, at the Parish Church, Kegworth, Hamilton Hartridge, Lt., R.N.V.R., M.A., M.B., Fellow of King's College, Cambridge, elder son of Henry and Sophy Hill Hartridge, of 19, Palace Court, London, W., to Kathleen, the only daughter of Hugo and Annie Wilson, of Springfield, Kegworth, Leicestershire.

MOLESWORTH-GRIFFITH.—On March 7th, at St. Anne's Church, Eastbourne, Surgeon Eric M. Molesworth, R.N., to Ethel A. Griffith, daughter of Mr. and Mrs. Isaac Clark Griffith, of The Chace, Eastbourne.

SMERDON-WHITE.—On March 7th, at the Church of St. Mary Magdalene, Enfield, Edgar Wilmot Smerdon, M.D., F.R.C.S., Lieut., R.A.M.C. (T.C.), son of Colonel and Mrs. F. G. B. Smerdon, of Oaklands, Binfield, Berks, to Hilda Mercedes, daughter of the late Mr. John White and Mrs. White, of Valencia, Spain, and "Alameda," Palmerston Creseent, London, N.

Deaths.

BARNES.—On March 6th, at Merstham, Surrey, Arthur Richard Barnes, M.D., aged 65.

BARNICOT.—On March 10th, at Queen Street, Hitchin, Joseph Barnicot, M.D. Cantab., of typhoid fever.

BENNETT.—On March 5th, at "Hillside," Upper Lydbrook, Ross-on-Wye, of pneumonia, Edward Bennett, L.R.C.P. and L.R.C.S. Edinburgh, son of the late Edward Augustus Bennett, of Marsden Hall, Nelson, Lancashire.

BIRD.—On March 10th, at Sutton Oak, Charles Thomas Grant Bird, M.A., M.B., Ch.B., son of Canon Bird, aged 32 years.

GRANT.—On March 8th, at Reay House, Inverness, Lieut.-Col. R. A. P. Grant, late 43rd Light Infantry and Army Medical Service.

HAYES.—On March 6th, at Highfield House, Basingstoke, Hawkesley Roche Hayes, L.R.C.P., J.P., aged 80.

LANDALE.—On March 8th, at Dunholme, Cheltenham, Deputy Surgeon-General James Landale, M.D., late R.A.M.C., in his 80th year.

PITTOCK.—On March 5th, George Mavris Pittock, M.B. Lond., F.R.C.S., F.R.M.S., of Winton, Canterbury, formerly of Margate, aged 84.

RIDGE.—At "The Platanes," Denmark Hill, Captain Percy Brewster Ridge, R.A.M.C. (T.), aged 33 years.

THOMSON.—On March 6th, at Oxford, suddenly, Theodore Thomson, C.M.G., M.A., M.D., late Assistant Medical Officer, Local Government Board, aged 57.

UNDERHILL.—On March 10th, at Mountjoy, West Bromwich, Thomas Underhill, M.D., J.P., in his 93rd year.

WHITE.—On March 5th, at 59, Victoria Road, South Southsea, Thomas Charters White, M.R.C.S. Eng., &c., late of Belgrave Road, S.W., in his 88th year.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX"

VOL. CLII.

WEDNESDAY, MARCH 22, 1916.

No. 12.

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

THE correspondence between Dr. Dr. Hayes and Maurice Hayes, the Secretary of the Sir A. Keogh. Irish Medical War Committee, and Sir Alfred Keogh, to which I briefly referred last week, will be found on page 266 of the present issue. Dr. Hayes calls the Director-General's attention to the following two paragraphs taken from the "Periphery" of March 8th:—

"That neither the one nor the other of these responsible and well-informed officials" (Sir Alfred Keogh and Mr. Tennant) sees any present need for increasing the existing number of officers in the R.A.M.C."

"On the one hand we know on unimpeachable authority, that the Director-General does not want any more medical officers, a fact which, on the face of the numbers enrolled, must be perfectly obvious to any thinking person."

In the course of his letter Sir Alfred Keogh says "The statement is entirely false. It is very far from anything I have ever said." I had, of course, no desire to misrepresent the Director-General, still less had I any object in so doing. The error, if error there was, was one of interpretation of an apparently unambiguous official statement. I take from the Parliamentary Intelligence on page 274 of the *Lancet* of January 29th the following: "Thursday, January 20th. Supply of Medical Men for the Army. Mr. Tennant (Under-Secretary for War), answering Mr. Lynch, said, 'Thanks to the patriotism of the Medical Profession, there is no present anxiety regarding the supply of doctors for the Army,' " a statement which must clearly be taken to reflect the view of the Director-General.

Now, Sir Alfred Keogh has himself been understood to use very similar words to those employed by Mr. Tennant, and he certainly uses them in the letter which appears on

The Facts. page 266: "There is," he says, "no present necessity for increasing the number of doctors with the armies abroad," a sentence which, in the absence of the modifying clauses which follow, could only be taken to mean what Mr. Tennant was understood to mean and what Sir Alfred Keogh has himself been quite honestly and sincerely taken

to mean by many in search of information. One occasion on which this meaning was put upon his words must surely be within the recollection of the Director-General. The expressions, "entirely false" and "very far from anything I have ever said," are thus clearly, to say the least, very inappropriate. It is not necessary to pursue this matter beyond expressing the opinion that, as qualifying clauses appear to have been necessary, it is a pity that they were not used, and insisted upon, before this letter was written.

The Atmosphere.

BUT it is never just to characterise a statement apart from the atmosphere in which it is made, any more than it is fair to criticise a sentence without reference to its context. What I said in the above-quoted paragraphs must be considered in connection with the question with which I was dealing. On the one hand there was Mr. Tennant's answer in the House, which said that there was "no anxiety" about the supply of medical men for the army; on the other, there was what I ventured to describe as "the shrill hysterical minatory shriek of the Central War Committee which enjoins upon all and sundry the urgent necessity of immediate attestation." The "no present anxiety" of Mr. Tennant and "The credit of the profession is at stake; go and enrol at once" of the Central War Committee create two atmospheres which are mutually exclusive; the one brings the other into high relief. Being a simple-minded, law-abiding person, I naturally preferred the official atmosphere.

An Important Estimate.

It now looks, however, as if the shriek were nearer the true tone than the note of confident official equanimity which, on January 20th, was sounded from the Treasury Bench. Government Departments have a way of withholding information which, while seemingly of no value to the enemy, would be immensely helpful to those at home. A good instance of this is provided in Sir Alfred Keogh's letter. He now tells us for the first time—I think I am right in saying that it has never before appeared in print—that he requires 150 doctors a month in order to make up

for what may be called normal wastage—i.e., sick, wounded, and time-expired men. This is a very important estimate, the explanation of which, inasmuch as it puts a totally different complexion upon the calls for enrolment which have been issued by the Central Medical War Committee, is more important still. An earlier official statement to this effect would have prevented much misunderstanding and have saved much trouble. Such an estimate as this is both intelligible and reasonable, and will do more to encourage enrolment than many circulars.

The Medical War Committee had this estimate of the Director-General's behind them, their tone of urgency would certainly seem to be justified.

Nevertheless, I still think that some of the methods employed to emphasise that urgency were regrettable. In the "Periphery" of March 8th, to cail attention to a threatening note which I deplored, I italicised a passage from one of these circulars which hinted that certain privileges might be withheld from "those practitioners who fail to enrol with our committee." With the same end in view I now italicise a passage from a printed post-card circular sent out from 429, Strand, dated March 11th, 1916. "*Men holding the Certificate of Enrolment may be employed in part time military work, irrespective of their age, whereas other men will not be employed on such work unless they are over 45.*" The fact here stated is, of course, correctly stated, but no one can pretend that it is tactfully stated. Such are not among the best methods of persuading the reluctant.

In this connection I may perhaps suitably deal with the laconic enquiry of a correspondent who writes to me saying, "What is the matter with the Central War Committee, and why do you gird at the British Medical Association?" The proper answers to these two questions are very much intermingled, but I will endeavour to unravel the rather tangled skein. In the first place I would wish to make it quite clear that not only have I nothing against a Central War Committee as such, but that, if properly constituted, I regard such a body as, in this crisis, essential to the interests not only of the profession but of the nation. If, in my view, there be anything "the matter" with the Central War Committee, it is not inherent in the principle. On some questions of detail I confess to the opinion that the existing organisation might be very much improved, and the direction in which I feel that improvements might be effected I will now endeavour to indicate.

Personal Grievances. But let me say at the outset that I do not in any way associate myself with the rather paltry personal grievances which have appeared in the *Daily Chronicle* and elsewhere.

The young gentlemen who don the King's uniform for service abroad must be made to realise that they take service, not for their own honour and glory or for the purpose of enlarging their opera-

tive experience, but in order to serve their country in its hour of need. If Mr. Jones, with the blushing honours of the F.R.C.S. freshly placed upon his brow, is asked to wash bottles or to dress ulcers he must understand that such is, for the moment at any rate, the job which has been allotted to him, and however *infra dig.* he may conceive it to be, he is there to perform it to the best of his ability. If he is a patriot and a gentleman he will do it uncomplainingly, in the full confidence that he will, as soon as possible, be given something to do which is more in consonance with his special training and his proved abilities. In all human endeavour grievances are sure to occur, and it is bound to happen that some talent is wasted; but these individual cries of distressed vanity find no sympathetic echo in, at any rate, one breast.

By this I must not be understood to mean that I regard all doctors as **Discriminate.** merely doctors. I have in these columns frequently urged the opposite opinion, and I adhere very strongly to the views that I then expressed. But what can be done and ought to be done after eighteen months of experience is a very different thing from that which has to be done when the nation is surprised into a species of warfare for which, rightly or wrongly, no provision had been made. Sir Alfred Keogh and his coadjutors did the best they could under very trying conditions, and though that best may not have been the ideal best, it was, in the circumstances, a very good one. Let us in such matters refrain from wild and weak complaining, and "forgetting those things which are behind and reaching forth unto those which are before," do what we can to retrieve our initial mistakes.

To return to the Central War Committee and the B.M.A., "The **C.M.W.C. and B.M.A.** matter" with the former is that it is too much tainted with the latter.

Without in any degree derogating from my general disapproval of the past record of the B.M.A., it is but bare justice to admit that this Association was the only one which had the machinery promptly and effectively to deal with the present emergency. That the Association cast itself into the breach, disbursed its money, showered its facilities and lavished the time and experience of its officials, it would be ungenerous and even churlish to deny. But it did more: it graciously co-opted several distinguished leaders of the profession, some of whom represent bodies of known antagonism to the Association. But even so, it did not do enough. It may seem a hard thing to ask of an Association which has done so much, to go further and efface itself entirely. In any other set of conditions such a demand would amount to an impertinence, but matters being as they are, it is the only course open to a patriotic body to pursue.

Pledges. THE enrolment form which doctors are now being urged to sign is an undertaking not to the King or to the Government, but to the Central Medical War Committee. It is

a pledge that the signatory will act in a certain way if and when he is called upon to do so. Now, I need not say more than that in the matter of pledges, as in the matter of diplomacy, the B.M.A. has an unfortunate record, and so long as the Central Medical War Committee is associated in men's minds with the B.M.A. so long will the reluctance to give this particular pledge be manifest, and very reasonably so. If the Central Medical War Committee is to secure the full confidence of the whole profession, which it is most desirable that it should do, it must shake itself free from this atmosphere. It must ask of the B.M.A. that the latter should consent to remove the remaining marks of identification between the two bodies and enable the Central Medical War Committee clearly, definitely and convincingly to announce that it has no connection whatever with the British Medical Association.

Now, what is going to convince the profession on this point? The answer is plain enough. Three things. The first is an assurance that the B.M.A. will be reimbursed for the money which it has patriotically expended on this scheme. The second is an intimation that the Central War Committee has arranged to hold its meetings elsewhere than at the offices of the Association, 429 Strand. The third and, in one sense, by far the most important, is an announcement that the present Secretaries of the Central Medical War Committee, one of whom is a Secretary of the B.M.A., and the other a very active and prominent, but not a very tactful, member of the Association, have been replaced by two Secretaries, preferably laymen, but certainly not members either of the Central Medical War Committee or of the British Medical Association. The first two points present no real difficulties; it is the third which is the crux. Dr. Cox and Mr. Bishop Harman are admittedly "British Medical" men, and the secretariat of the Central War Committee has unfortunately shown itself typically "British Medical" in its methods. If these two gentlemen would consent to be persuaded by their interpretation of the word "patriotism" into recognising that they are not diplomatists, and by giving effect to that recognition by resigning their present posts to make way for more acceptable occupants, they would do a great deal to retrieve the errors for which they are held responsible.

The Reason. THE necessity for securing the full confidence of the profession in the Central War Committee cannot be too strongly emphasised, and no sacrifices are too great, if by making them, this end can be securely attained. Every member of the profession of military age is being invited to enrol; that is to say, he is being invited to place himself, his family, his professional prospects, and his financial position unreservedly in the hands of a certain body of professional men. If he is convinced that this body will give a sympathetic ear to his difficulties and will bring a judicial spirit, an understanding mind, and a tact-

ful manner to the solution of the immensely complex and delicate problems which it will be called upon to decide, then he will have little or no hesitation in accepting the invitation to sign the enrolment pledge. If, however, he continues in a condition of serious doubt on these points, he will remain elusive, though unmoved. And, let it be quite clearly understood that, rightly or wrongly, his confidence in the British Medical Association is at the best not of the quality which will move him to refer doubtful and intimate points to the jurisdiction of a body so closely connected with the Association as the Central Medical War Committee is now reputed to be.

A Strong Committee. THERE are other reasons why the Central Medical War Committee should be so constituted as to command the unqualified approval and complete confidence of the profession. There is at present no organisation which exists for the purpose of voicing the views and defending the interests of medical men *vis-à-vis* the public. We are not adequately represented in Parliament, and although the House of Commons is taking a great interest in our affairs at the moment, this interest will certainly prove to be as evanescent as the other spasmodic signs of appreciation which during the last twenty years have occasionally manifested themselves in the same august assembly. The civilian medical men are now supplying 90 per cent. of the doctors employed by the military authorities, and yet there is no recognised body—recognised, that is, either by the doctors or the authorities—which can urge upon the latter the views or the claims of the former. A Central Medical War Committee which derives its strength not only from its *personnel*, but also from general professional approval, could undertake such functions with great advantage to both parties.

An Example. THERE have, for example, been complaints of the application of undue military rigidity in dealing with those civil doctors who are engaged on war service. There is very little doubt that many of these complaints are quite reasonable. The military reply is, however, equally reasonable. It is very human and, in a sense, very logical. It says that as soon as a man is in military uniform he must bend his neck to the military yoke, and do as he is bid. Now, if there were a really strong Central Medical War Committee it could, and would, see that this rigidity in suitable cases would be transformed into a certain degree of elasticity. But until pressure is brought to bear upon the military arm, it is not likely to alter its traditional methods. I understand that Sir Alfred Keogh, who is always a doctor first, and a soldier afterwards, has done his best to introduce some elasticity, and in individual cases he has succeeded; but what is one among so many?

SINAPIS.

A MILITARY hospital to accommodate 400 patients is to be erected at Bognor.

THE PSYCHOLOGY OF THE CONSCIENTIOUS OBJECTOR.

WHENEVER the governing authority decrees that for the good of the country certain things must be done although they may involve a degree of discomfort, dislike or hardship upon some individuals, the conscientious objector is sure to make his appearance. So we have conscientious anti-vaccinationists, anti-inoculationists, anti-compulsionists, etc. It was therefore to be expected that "Conscience" would be invoked to secure immunity from war service by those who prefer to have their own safety at the expense of the lives of others.

And so it has turned out. No consideration of the needs of the country, no appeal from the constitutional leaders, no sense of shame can galvanise these selfish objectors into anything but resistance to being themselves obliged to join and help those who are using their strongest efforts to fend off and annihilate the enemy. Even in countries where universal service has been for years a factor deep-set in the mind of the male population, there are to be found many who wriggle and twist in all conceivable directions to get out of the obligation to serve, but so well are those shirkers known that they have a short shrift, and in only a few instances do they obtain exemption. Of course, they must give a reason for their defection. They cannot claim bad health, for that would be disallowed by medical examination, and so they say that it is against their "conscience," and through fear lest this should be interpreted as cowardice (which in most cases it really is) they base their scruples upon religion with the view of resting their motives on the highest platform which they suppose will help them. Alas! they show a sad ignorance both of Religion and Psychology!

The conscientious objectors base their secession from their fellows on the ground of possessing some special faculty which they call their conscience, or moral sense, or instinct, which regulates and accounts for their conduct. Unfortunately for them there is no such faculty! Modern psychology is in nothing more busied than in showing that this faculty process, the innate presence of a power such as conscience or free will does not exist; it is an exploded theory and is untenable. The objectors are equally wrong on religious grounds when they say that the shedding of blood is against scriptural teaching. Why! the whole of the Christian religion rests upon it! The crucified Christ's body and blood were obliterated for the sins of the whole world! And if these recalcitrants read the Old Testament they will see that thousands upon thousands of men, women and children were killed by Divine command. Where, then, comes in their plea that it is against the Christian religion to shed blood?

What the conscientious objector calls his conscience is simply a strong feeling, conjoined with an idea which leads to action, and the leading motive is the one most favourable to himself. It is, in fact, his character which is the source of both his conscience and his will. For instance, a man feels that in

reality he is a coward; at the same time he knows that it is his "duty" as a citizen to defend his country when called upon; but the feeling of fear prevails over the sentiment of duty, and so he invents excuses and says that his conscience is his authority and prompter, the fact being that he has manufactured a conscience which is in no way an innate moral sense. Circumstances might arise, such as the offer of a lucrative post free from danger, where he would find another conscience which he would say prompted him to enlist! So that he may have no end of consciences, and there is no such thing as an innate guiding conscience faculty—it is entirely a matter of expediency, and a man may have as many "consciences" as he has feelings and ideas. When the feeling is very strong through thinking very intently upon one subject to the exclusion of others, his "conscience" becomes very "clear"; he then becomes a mono-ideist and intolerant of all other obligations. No one cares to risk his life nor to kill others unless he is obliged to do so by patriotic considerations, and as the conscientious objector bases his objection to military service on the ground of not wishing to shed blood, he must accept this alternative, either that he is a coward and is afraid to risk his life when the public and private necessity arises, or else that he is an undutiful citizen when called upon by the State and freed from blood-guiltiness by the articles of the established church of his country.

Many of the conscientious objectors are insane; others are mono-idealists with no sense of logic or ethics in their arguments. They are really Casuists, a Casuist being defined as one who reflects about his duties and tries to bring them into line with some intelligible moral standard. They remind one of Fielding's "Parson Twackem and Philosopher Square," who only took to arguments when they wanted to reason themselves out of some obvious duty, and they bear out Rousseau's dictum that "Conscience is the best of Casuists." Conscientious objectors were well known in Shakespeare's time, for he makes Clarence's murderer say, "Conscience is a dangerous thing, it makes a man a coward," and again in Timon he says that policy sits above conscience.

Those who, being in good health and otherwise eligible, decline to follow the country's call are at the least unpatriotic, and should not be allowed to screen themselves under their selfish objections. Why listen to such invertebrate disciples of Apemantus, who pray for no man but themselves! The State should make them go, just as it makes them pay taxes or light up a bicycle at sunset, or go to prison if they neglect their children. The conscientious objector says he follows his conscience. It is just the other way about; his conscience is his servant, not his guide, and if he thinks he hears it talk he tries to smother it.

T. CLAYE SHAW, M.D., F.R.C.P.

DR. W. H. WILLCOX, M.D., F.R.C.P., Lieut.-Col., R.A.M.C., has been granted the rank of Colonel, on his appointment as consulting physician to the Mesopotamia Expeditionary Force.

CURRENT TOPICS.

Proposed Ophthalmic School in Glasgow.

At a recent meeting of the Glasgow School Board a motion was submitted that immediate steps be taken to provide classes for children of school age having defective sight and myopia, the school to be as centrally situated as possible. It was agreed to remit the motion to the joint consideration of the Special Schools and Medical Inspection Committees.

There is every reason to wish this scheme well. Town children have woefully deficient sight, especially for long distance. Their eyes have not had the necessary training, their field of vision being confined to the streets of a closely built town. It is different with children reared in the country or at the coast. They have the chance of exercising their vision over big distances, with the happiest results.

It seems interesting to watch the development of the School Board, *quâ* School Board. The members thereof (usually Kirk nominees) are strictly forbidden in any way to interfere with the purely educative portion of the school-work. Perhaps as well: their function is to say ditto to whatever is decreed by a gentleman sitting lonesome and "far awa' frae bonnie Scotland." He is called "My Lords." But these energetic gentlemen will not rest: they effloresce: they break out, like a carcinoma, in some new unexpected quarter. Now it is "baths," next it is "clogs," again school clinics, with special stress on pediculi capitis. Oh! they are wonderful. They have heard of the "Mens sana in sano corpore," and as "My Lords" holds on by the "Mens": they look on the "corpus vile"—and the viler the better—as their shekinah. So knowing that the medical profession is easy to exploit they have called in members of our profession to help them in their good work. We have responded—for salaries that we don't boast about.

State Registration of Nurses.

We referred a few weeks ago to the proposed "College of Nursing" of which Mr. Arthur Stanley is the chief promoter. There have been two conferences on the subject at which representatives of those interested in the State Registration of Nurses have been present. It is only right to say that Mr. Stanley has set himself to meet criticisms of his project in a most conciliatory manner, and has shown a desire to have the matter fully discussed. Some of his supporters and advisers have not, it is true, been so judicious, but that may pass. The upholders of State registration will, however, be well advised not to let themselves be persuaded to give up their demand by any show of reasonableness on the other side. The claim for State registration is clear, and it is made not only by the overwhelming majority of trained nurses, but by the majority of the medical profession. A voluntary enrolment will not fulfil any of the purposes of a State register, but it may easily block the way. Over and above this, Mr. Stanley's scheme contains the entirely objectionable condition of government by a self-nominated and irresponsible committee containing an unknown proportion of lay people. Much play has been made by the promoters of the scheme by the misleading analogy of the proposed College of Nursing with the Incorporated Law Society. As a matter of fact, the control of the roll of solicitors is in the hands of the Lord Chancellor and not of the Incorporated Law Society, but, apart from this, we should not envy the man who had the audacity to

propose to the solicitors' profession that the government of the Incorporated Law Society should be given to a self-nominated committee consisting of a mixture of solicitors and well-meaning busybodies, who have no knowledge of law but were interested in the education of solicitors. This would be a fair parallel to what Mr. Stanley and his advisers suggest to the nursing profession.

Treatment of Wounds with Horse Serum.

PROF. LIGNIERES, at the Academy of Medicine, warmly advocated the use of horse serum as a dressing for wounds. He stated that fresh serum can easily be obtained in all large centres. One or more horses are kept from which every 15 or 20 days blood amounting to 10 or 12 litres, according to the size of the horse, may be obtained, the only precaution being to remove half the amount at one time, the half being drawn at an interval of 24 hours.

It is important to note that the second lot is always more active than the first. The serum may be used fresh, without heating, by means of compresses, renewed once or twice in 24 hours. If the serum has to be preserved, the author advises a certain quantity of carbolic acid to be added, but never more than half per cent. The carbolic acid should be added immediately after the serum has separated from the clot, and the preparation is then filtered on sterilised cotton-wool, or allowed to decant in a refrigerator.

School.

THE education question is only one aspect of the entire juvenile problem. It is not to be studied by itself, but in conjunction with such important factors as hygiene, home life, and, so far as is possible, the personal equation of each child in question. A contrast between our own haphazard methods of dealing with the training of the children of the poorer section of the community, and such as that now practised in the United States, reduces one almost to despair. The supervision of bodily health, and prompt rectification of minor disabilities, the efforts made to correlate the exertions demanded of each individual intellect with its own peculiar capacities, present such strong contrast to a cast-iron scheme which appears to regard a number of children congregated together akin to some such natural phenomenon as an autumnal flock of starlings. The merging of the individual in the community is an excellent preparation for adult civic life, but differential treatment, freely granted to such slight constitutions as those of flowers has also strong claims to be employed in the case of the young person. Merely to conform automatically to a fixed standard of dead knowledge should not be sufficient. To educate should comprise the development of mind and body in the true sense of development—should aim at popularising a type in whom mental and physical activities may be displayed as luting in joyful concord, to quote the felicitous words of George Meredith.

Medico-Social Work.

EVERY hospital physician or surgeon has felt how much his work suffers by his inability to keep in touch with his hospital patients once they have left his wards. An attempt to keep up a relation between a hospital and its past patients is being made in certain of the American hospitals, and an interesting account of the work done by the medico-social department of the Boston City Hospital is given in a recent number of the *Boston Medical Journal*. This department was started by

a committee of honorary workers whose duties were to visit patients after their discharge, to see that out-patients attended the dispensaries at regular intervals, and, where necessary, to make use of various charitable institutions on behalf of these patients. This visiting scheme is obviously of great use to the patients, particularly where hospitals are ill supplied with convalescent homes. The hospitals are benefitted in two ways: the patients may often be discharged sooner than would otherwise be possible, and the following up of these cases becomes a comparatively simple task. The importance of this work has been so fully realised that a number of other great hospitals in America have established medico-social departments, and it is stated that the financial support of the work may soon be undertaken by the hospital boards themselves. An extension of this scheme to our hospitals would be of great value. We all have to deplore the disappearance of our patients as soon as they are discharged, partly because we would like to see the after-effects of our treatment, and also because the treatment will often be of little avail if the patients return immediately to their former mode of life. When the war is over there will be thousands of women who have for the first time tasted the joys of regular occupation. Perhaps some members of the V.A.D.'s may take up this more prosaic work for the hospitals later on.

Greenock Doctors' Charges.

THE Greenock Trades' Council regret the action taken by the doctors in desiring to increase their charge for night calls. We like the flavour of politeness embodied in that blessed word "regret"; it is akin to the world of consolation in that blessed word "Mesopotamia." How dare these medical men, who have the wet, inestimable privilege of living in Greenock, ask for additional reward for night work? Every Greenock Black-squadder works for the same sum per hour by night as by day. Perhaps I do not believe that the forbears of the Greenock Trades Council hanged the monkey. That's the tradition. The truth is, to judge from their descendants, they skinned the poor brute.

Principle and Practice.

"It has been decided to invest the funds of the Aberdeen University Peace Society in the War Loan. The funds, the greater part of which were presented by Mr. Andrew Carnegie in pre-war days, stand at present at £200 of stock and £50 in the bank, and the whole of this will be invested in the War Stock. The majority of the members of the society are on military service, including the president, who was called up at the outbreak of war."

There is something Gilbertian in this announcement in the *Glasgow Herald* regarding the proceedings of a Peace Society and its dealings with their funds given them by the great Pacificator, Dr. Carnegie. Yet the awful temptingness of a 5 per cent. investment with guarantees would move more than an Aberdonian to look kindly on war stock. I can quite understand the officials of the society taking up arms (good fortune attend them), because the radical treatment of the problem of most quickly restoring peace is to kill the opponent of peace as swiftly and, if possible, as kindly as circumstances will allow. Perge, puer, and if anybody says you are illogical, you have always by you your city's bludgeon for interfering persons—"They have said: What say they: Let them say."

DR. FRANCIS J. H. BATEMAN has been appointed a J.P. for the County of London.

PERSONAL.

MR. GEO. E. BEAUMONT, B.A., University College, Oxford, has been elected to a Radcliffe Travelling Fellowship.

DR. JAMES HARRISON has received a handsome gift of silver plate from his pupils of the North Shields Nursing Division.

MR. S. W. COLE, M.A., of Trinity College, has been appointed University Lecturer in Medical Chemistry at Cambridge.

SIR A. H. KEOGH, Director-General of the Army Medical Department, has been admitted to the freedom of the City of London.

MAJOR MICHAEL J. MAHONEY, M.D., R.A.M.C., attached to the King's (Liverpool Regiment), has received the Territorial decoration.

THE Scottish Red Cross has completed at Glasgow its first hospital ship for the Mediterranean service. The vessel has been named *St. Margaret of Scotland*.

MR. JAMES BERRY, F.R.C.S., who was taken prisoner in Serbia by the Austrians in November last, whilst in charge of an ambulance unit, has cabled that he has been liberated and is on his way home.

DR. W. W. KEEN, of Philadelphia, the well-known American surgeon, who is Emeritus Professor of Surgery in Jefferson Medical College, has been re-elected president for 1916, of the American Philosophical Society.

THE council of the Royal College of Surgeons have appointed Lieut.-Colonel C. J. Symonds, F.R.C.S., who is serving as a Surgeon to the Mediterranean Expeditionary Forces, to be the Bradshaw Lecturer for the ensuing collegiate year.

DR. T. J. HORDER is at present acting as medical adviser in London to the Anglo-Russian Hospital in Petrograd. He has been unable to join the staff of the hospital in the Russian capital, on account of the absence of Colonel A. E. Garrod, A.M.S.

COL. JAMES MONTGOMERY, C.S.I., has been appointed Red Cross Commissioner for British East Africa. The appointment is made by the Joint Committee of the British Red Cross Society and the Order of St. John, with the approval of the War Office.

SIR ST. CLAIR THOMSON, M.D., the Medical Society of London Orator for the year, has selected for his subject "Shakespeare and Medicine," and this year being the Tercentenary of Shakespeare, it will be of special interest. The date fixed is Monday, May 1st, so as to bring it in line with the official Shakespearian celebrations.

SIR GEORGE NEWMAN has resigned his post as Lecturer on Public Health at St. Bartholomew's Hospital owing to pressure of duties as Chief Medical Officer of the Board of Education. The vacancy has been filled by Dr. R. A. Lyster, of The Castle, Winchester, the Lecturer on Forensic Medicine at the hospital.

WE are very pleased to notice the appointment of Dr. John Gilchrist as Oculist to the Victorian Eye Infirmary, Paisley, in succession to Dr. Cluckie, who has resigned after twenty-six years' yeoman service. Dr. Gilchrist is one of the capable younger oculists of Glasgow, and will be a worthy successor in the post now vacated. In addition to his large experience in eye diseases, he has been in Stobhill Military Hospital during the past year, getting varied experiences and acquiring merit in extra-ocular domains. We congratulate him heartily on his appointment.

ORIGINAL PAPERS.

ON FÆCAL FISTULA OF THE ABDOMEN.

By RUSHTON PARKER, M.B., B.S., F.R.C.S.,

Professor of Surgery in the University of Liverpool; Lieut.-Col., 1st Western General Hospital, R.A.M.C. (T.F.).

FÆCAL fistula of the abdomen can often only be remedied by operation, and a case in point is here related. But all cases do not require operation; in fact, most of those I have met with, having been slight cases arising under my own observation, and capable of being taken in hand before they have become chronic, have closed spontaneously when treated by a reduction of diet to broth, arrowroot, or other similar trifles that produce little or no waste, gas, or other source of intestinal distension.

One somewhat different was that of a youth admitted into hospital having a dozen or more abdominal fistulæ. The case was one of typhoid, mild no doubt, but said to have been treated at home, walking about, and fed on meat and potatoes! Some of the fistulæ were discharging fæces, others pus, and all were judged to be perforations of small intestine. The patient was now fed chiefly on beef tea, and the affected skin was covered with waterproof tissue, daily cleansed and re-applied under a draw-sheet. The sinuses discharging pus soon discharged only serum, those discharging fæces gradually discharged only pus and eventually serum, followed in every case by drying-up. The patient completely recovered, and never seemed to have been seriously ill at any stage of his malady. This is the principle on which I have always treated the few fæcal fistulæ of the abdomen that occurred now and then after operation and reduction of strangulated hernia. One such case, in a woman, discharged through a stitch-hole after umbilical herniotomy. Nothing was done beyond reducing the diet as above described, and washing away the fæcal discharge at the changes of dressing. In this and every case that I can remember the fistula dried up and got well.

Another case caused me much disappointment and anxiety for a time, being a left inguinal herniotomy, for the radical cure, in a healthy male private patient of 72, in July, 1894. The operation wound had practically healed in three days, but later an abscess formed, which was opened three weeks after the herniotomy operation, and became a fæcal fistula ten days later. This took nearly two months to dry up, but did so completely, thanks to the willing co-operation of the patient, who fasted courageously the whole time. The patient lived an active and healthy life, free from hernia and impulse at the scar, and only died in his 90th year. Why the fistula occurred I never knew, but could only imagine that, by some mishap in passing Macewen's blunt hernia needle, with the suture to attach the folded hernial sac to the inner side of the abdominal wall, a piece of bowel, or mesocolon close to the bowel, had been inadvertently perforated. In the other cases the fistula probably occurred through ulceration of bowel at the part nipped in the strangulation; but in the last, not only was there no strangulation, but the hernial contents were omentum only.

CASE TREATED BY OPERATION.

A married woman, æt. 34, was submitted to

median abdominal section by Dr. E. T. Davies at the Samaritan Hospital, Liverpool, in January, 1903, for severe pain in the left groin and hypogastrium. He removed the left ovary, which appeared to be tuberculous, with matted appendages, closely adherent to the upper rectum. The patient was relieved of her pain and most of the wound healed well; but a fæcal fistula formed in it and persisted till the following May, when Dr. Davies transferred her to my care at the Liverpool Royal Infirmary. At this time fæcal liquid issued from the fistula, but nothing from the anus except when she took opening medicine.

On May 25th, 1903, after having had fæces washed out of the rectum, I performed left inguinal colotomy, the sigmoid flexure being attached unopened round the wound. At this operation the position of the fistula was found to be on the front of the upper rectum, at the pelvic brim, as previously ascertained by Dr. Davies. Nine days later the colon in the wound was laid open, flatus issuing. Fæces continued to reach the rectum, which was cleared by enemata from time to time. A fortnight after the colotomy the old fistula in the median scar was scraped and packed with gauze. By July 20th most of the fæces issued by the opening in the colon, and the old fistula was found to be closing. On November 10th the superficial part of this fistula was laid open, scraped, and treated with pure liquid carbolic acid, washed off again with spirit. A fistula of the small intestine was also found, scraped, carbolised, and closed with sutures. By the end of January, 1904, nothing but a small sinus remained of the old fistula, and some fæces now all the time reached the rectum. On February 8th this sinus was scraped and carbolised, also the edges of the colotomy opening, after which the bowel was detached from the integuments, re-united by suture, and dropped into the deep parts of the wound, which latter was dressed with a glass tube and gauze pack. No further fæces issued from the front of the abdomen, and she went home on March 8th, 1904, wearing a small dressing. A fortnight later healing was completed on the issue of a stitch. She continued well, and was seen a year later all right.

On November 3rd, 1915, Dr. Davies sent her to see me, and she was found in every respect well, the scars being white and recessed, and no protrusion anywhere on coughing.

MRS. MARIA LONG, Mother of Captain R. W. Long, R.A.M.C., Queenstown, died on March 13th, at her son's residence, Kilva, three miles from Midleton, aged one hundred and four years. She retained her faculties in full to the end.

DR. THOMAS BUSHBY, M.B., C.M., M.R.C.P., of 47, Rodney Street, Liverpool, assistant physician to the Liverpool Hospital for Diseases of the Chest, hon. physician to the David Lewis Northern Hospital, lecturer on and examiner in clinical medicine at the University of Liverpool, left estate valued at £4,967 17s. 4d. gross, with net personalty £4,897 4s. 3d.

THE NORMAL STOMACH: ITS SIZE, POSITION, FORM, TONE, PERISTALSIS, AND MOBILITY FROM A RADIOGRAPHIC STANDPOINT.*

By C. WINFIELD PERKINS, M.D.,
New York.

DR. JOHN B. DEEVER, the noted surgeon, in his splendid *Anatomy*, describes the stomach as the most dilated part of the alimentary canal, situated in the left hypochondriac and epigastric region, between the œsophagus and the small intestine, and retained in position by the œsophagus and by reflections of the peritoneum. The more capacious extremity of the stomach, which is directed toward the left side of the body, is the cardiac end; the narrow extremity, which is directed toward the pyloric side, is the pyloric end; and the intermediate portion is the body of the stomach. The portion of the cardiac end projecting to the left beyond the œsophagus is the fundus, or great cul-de-sac of the stomach and the slight dilatation of the stomach at the pyloric end is the antrum of the pylorus or the lesser cul-de-sac. The stomach has an anterior and a posterior surface. These surfaces are somewhat crescentic in shape. The upper and the shorter margin of the stomach is the lesser curvature and the lower border is the greater curvature. The part of the stomach occupying the left hypochondriac region is the cardiac end of the stomach and the body, three-fourths of the organ being in that region. The portion of the stomach occupying

and rarely found in women. The common type is the fish-hook or J type. Its axis is vertical and it is found in nearly all women and many men. Tonus is the ability of the stomach to hold its contents firmly. Stomachs are classified by Schlesinger according to the tone, as hypertonic, orthotonic, hypotonic, atonic, or subtonic. The hypertonic is the steer-horn type, the orthotonic the fish-hook or J type, and the hypotonic is broad at its base and the bismuth meal usually settles down, leaving the upper portion partially relaxed. The atonic or subtonic stomach hangs like a loose bag well down into the pelvis with the pars media and the pars cardia collapsed.

The capacity of the normal stomach ranges from twenty-four to thirty ounces, any departure from this being usually abnormal. The only positive fixed point of the stomach is the cardia; the other points or portions should be freely movable on palpation under the fluorescent screen. The gastric outline is smooth and regular. A slight indentation may often be noticed below the cardia, due to the spleen, and should not be mistaken for a deformity; a deeper depression is observed at the pylorus or antrum of the pylorus and also by the peristaltic waves. A peristaltic wave usually begins at the pars media and becomes deeper as it advances toward the pylorus. The wave is always more pronounced on the lesser curvature than on the greater. At the pyloric end it disappears and the food passes into the pars ascendens of the duodenum, usually outlining the bulbus duodeni. This is called a stomach cycle, a functional process that begins over again in the normal stomach in from fifteen to twenty seconds.

Following is the report of the examination of fifty-eight normal stomachs radiographed in the vertical position filled with the bismuth meal (buttermilk and bismuth subcarbonate): Twenty-eight in females, ages from twelve to eighty-two years, thirty in males, ages from seventeen to sixty-six years, or fifty-eight cases in all. Types of stomachs found, males, hypertonic 5, orthotonic 22, two with hypotonic tendency, hypotonic 1. Females, hypertonic 3, orthotonic 13, hypotonic 12. The tendency of the male stomach is therefore toward hypertonicity, while that of the female is toward hypotonicity.

The axis of the stomach is the direction or position of the stomach in relation to the median line.

All the hypertonic stomachs had the axis oblique; thirty orthotonic stomachs had the axis vertical; nine orthotonic stomachs had the axis oblique; ten hypotonic stomachs had the axis vertical; one hypotonic stomach had the axis oblique. The average normal axis of the stomach is, therefore, vertical and parallel to the median line, but it sometimes may be slightly oblique.

We shall now discuss the position of the lowest point of the greater curvature in its relation to the interspinous line; the umbilicus is no longer used as a point of measurement, as it does not remain in a fixed position under the influence of various postures. Thirteen stomachs of the orthotonic type averaged from one to four inches above the interspinous line and from one to two inches to the left of the median line. In nine of the orthotonic type the greater curvature (lowest point) averaged one to two inches below the interspinous line and one to two inches to the left of the median line. In four cases the lowest point of the greater curvature was on the level with the line and one inch to the left. In seven cases the lowest point was above one and one-half inch and median in position. One stomach of the orthotonic type was one inch above the line and one inch to the right. In one case the greater curvature (lowest point) was one inch below and

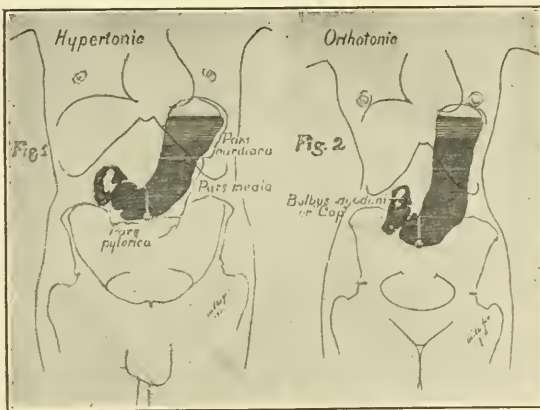

FIG. 1 illustrates the hypertonic type of stomach with its anatomical subdivisions, pars cardica, pars media, and pars pylorica.

FIG. 2 illustrates the orthotonic type of stomach with the filled bulbus duodeni, frequently called "cap," having a similarity to the Liberty cap of the French Revolution. (Drawings after Mills.)

the epigastric region is the pyloric end, and is in contact with the under surface of the liver.

Such is the anatomy of the operating room and the *post-mortem* table. Radiography has given us an entirely new anatomy, that of the living in a normal functioning capacity, and it is my desire in this paper to show the normal position and physiological action of the stomach in comparison with the old anatomical viewpoint. Two types of stomach are in existence (Haudeck's classification), the steer horn and the fish-hook. The "steer horn," as the name implies, resembles a horn of the steer, having a broad base and a narrowing toward the pylorus. Its axis is always oblique in the abdomen. This type is comparatively rare and is usually associated with deep-chested and muscular men

*New York Medical Journal, January 8th, 1916.

one inch to the right. Therefore the position of the greater curvature (lowest point) in the orthotonic type of stomach may be from one to four inches above, at the same level as, or one to two inches below the interspinous line and one to two inches to the left.

The lowest point of the lesser curvature of the orthotonic stomach in relation to the same line was as follows: In twenty-seven cases it averaged from

half inch to two and a half inches above the interspinous line and from one-half to one and a-half inch to the left. In one case the lesser curvature was at the level of the line; in two cases the lesser curvature was at the level and placed in the median line; in one case the lesser curvature was three-quarters of an inch below the line and to the left.

We shall now discuss the relative position of the pylorus, in the orthotonic stomach where the interspinous line is taken as the point of measurement (the measurement was taken at the first portion of the pars pylorica and not precisely at the pyloric ring) was as follows: In twenty-five cases the pylorus was from four and a-half inches to one and a-half inch above and from one to three inches to the right of the median line; in twelve cases the pylorus was placed from two to four inches above the interspinous line and in the median line; in three cases the pylorus was to the left of the median line and from two to three inches above the interspinous line. Therefore, in the orthotonic stomach the average position of the pylorus is from two to four inches above the interspinous line and one and a-half inch to the right or in the median line.

The position of the pylorus in the hypertonic stomach was as follows: In eight cases the pylorus averaged three inches above the interspinous line and from one to three and a-half inches to the right.

The situation of the pylorus in the hypotonic stomach was, in eight cases, two inches above and

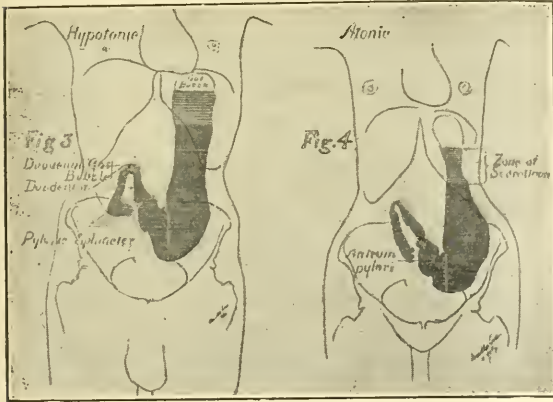

FIG. 3 illustrates the hypotonic stomach with Magen Blase or gas bubble in the cardia, pyloric sphincter, pars ascendens, in the duodenum, and descending portion of the latter.

FIG. 4 illustrates the atonic or subtonic type of stomach, with zone of secretions, and pyloric antrum. (Drawings after Mills.)

one quarter to six and a half inches above the line and one quarter to two and a half inches to the left; in nine cases the lowest point of the lesser curvature was in the median line; in two cases the lowest point two and a half inches above and one-half inch to the right; in one case the lowest point was at the level and to the left. The average position of the lesser curvature in the orthotonic type of stomach may be from one to six inches above the interspinous line and is usually to the left of the median line.

The position of the greater curvature (lowest point) in the hypertonic stomach was as follows: In four cases the lowest point of the greater curvature was from three to four and a half inches above the line and from one to two inches to the right of the median line; in one case the lowest point was to the left; in three cases the lowest point was two and a half inches above the line and situated in the median line. Therefore, the lowest point of the greater curvature in the hypertonic stomach is usually three to four inches above the interspinous line and one to two inches to the right.

The lowest point of the lesser curvature in the hypertonic stomach was as follows: In eight cases the lowest point was placed from two and a half to seven and three-quarter inches above the line and from one to three inches to the right of the median line.

The position of the lowest point of the greater curvature in the hypertonic type of stomach averaged in ten cases from three-quarters of an inch to three and a-half inches below the line and one to two inches to the left of the median line. In one case it was in the median line at the level of the interspinous line. The average position of the lowest point of the greater curvature in the hypotonic variety of stomach is, therefore, from one to three inches below the line and from one to two inches to the left of the median line.

The position of the lesser curvature in the hypotonic stomach in eight cases averaged from one-

FIG. 5.—Typical peristaltic rhythm of the stomach (after Reider and Groedel).

from one-half to three inches to the right; in three cases, two inches above and in the median line; in one case two inches above and one inch to the left. The situation of the pylorus in the hypotonic stomach should be, therefore, from one to two inches above the interspinous line, in the median

line, or about one inch to the right of the median line.

The length and diameter of the three types of stomach were found to be:—

Orthotonic stomach.—In thirty-five cases the length was six and a-half to twelve inches with an average of eight to ten inches; in thirty-five cases the diameter was two and a-half to seven and a-half inches or an average of three to three and a-half inches.

Hypertonic stomach.—In eight cases this averaged seven to ten inches in length, and three and a-half to four and a-half inches in diameter.

Hypotonic stomach.—In thirteen cases it averaged eight and a half to thirteen inches in length. The general average was eleven to thirteen inches. The diameter in the same cases was from two and three-quarters to three and one-quarter inches.

As to the tonus of the different types, in the ortho-

toward hypertonicity, while that of the female is toward hypotonicity.

The stomach is not, as a rule, as high in the abdominal cavity as many textbooks of anatomy teach. There is no structure in the human body, however, that has such variations in form, tone, and position.

The radiographic examination, either by the fluorescent screen or plate, is the only accurate method of ascertaining the anatomical position, form, peristalsis, and mobility of the stomach. Therefore, revolving in mind that the type of stomach fits the patient, a chart of the relative positions of the stomach should be of service to the clinical diagnostician in locating pathological lesions of the organ; that is, if he has not X-ray methods at hand. Such a chart should also be of service to the radiological technician in locating points for radiographic work.

The examinations and accompanying radiographs were made in the röntgenological department of the Post-Graduate Hospital, and I desire to express my appreciation to Professor Hirsch, who is in charge of the laboratory, for his valuable suggestions.

FIG. 6.—Phases of the peristaltic waves of the stomach as visualised with the fluorescent screen or serial plate.

tonic twenty-eight cases were normal, six exaggerated, three diminished; in the hypertonic, two cases were normal, six cases increased and in the hypotonic, three cases were normal, ten cases diminished.

CONCLUSIONS.

Peristalsis does not seem to exert any influence on the tone of the stomach, for we may have exaggerated peristalsis with a hypotonic stomach and diminished peristalsis in a hypertonic stomach.

There are no determined fixed points of any type of stomach in the abdominal cavity, except the cardiac portion.

A stomach may be of any of the types and yet be normal from an X-ray standpoint.

The average normal stomach is orthotonic. The usual position of the orthotonic stomach is as follows: Greater curvature (lowest point) one to two inches above the interspinous line, either median or to the left; lesser curvature (lowest point) three to four inches above the same line, median or one to two inches to the right.

The pylorus is placed two or three inches above the line, in the median position, or one and a-half inch to the right.

The axis of the stomach is vertical and parallel to the median line.

The length is eight to ten inches and the width three to three and a-half inches.

The tendency of the male stomach is always

PLUMBISM AND BRIGHT'S DISEASE.

By PROFESSOR WIDAL, M.D.,

Physician to the Cochin Hospital, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

A MAN, forty years of age, was admitted to hospital complaining of abdominal and lumbar pain. By way of antecedents he remembers having had scarlatina and articular rheumatism at the age of seven, and it is to be noted that from the age of 16 he became a house painter. He is married, his wife has had six children and one miscarriage at about the fifth month. He has had several well-marked attacks of lead colic, the first when 27 years of age, for which he remained under treatment at the hospital for a fortnight; a second at 31 years of age, and a third, not so severe as the previous ones, at 33. He has since continued his calling.

A year and a half ago he again had to take to his bed, on this occasion for very sharp pain in the joints of the toes, especially the big toe. The doctor whom he called in had no hesitation in diagnosing "saturnine gout." He had the urine analysed and found a good deal of albumen, so the patient was put on a lacto-vegetarian diet and theobromine.

Since that date the patient has been suffering from general lassitude and indisposition to work, with oedema of the legs which disappears during the night, lumbar ache and troublesome cramps. Since that time, too, he has been troubled by dysuria, micturition entailing an effort, and he passes barely two pints of urine in the twenty-four hours.

The slightest effort causes shortness of breath with palpitation and sharp pain in the precordial region with a distressing feeling over the phrenic spot, opposite the intersection of the external margin of the rectus and the tenth rib. Then, too, he has been losing flesh.

Lastly, he was a month in hospital under the care of Dr. Oettinger, in September last, when he was given digitalis which greatly relieved him. The blood was examined in respect of urea, which was found to be present to the extent of upwards of one gramme per litre.

He was discharged from hospital but was obliged to return a few days later, and now, after a fresh period outside, he returns to us with the symptoms set forth above.

When we look at him he is seen to be anæmic, his face is puffy and the features are drawn. He is in a state of perpetual torpor. Examination of the eyes shows slight yellowness of the conjunctivæ, but nothing amiss with the pupils.

He is short-winded and his tongue is coated. He has lost his appetite and constantly suffers from nausea with occasional vomiting.

On uncovering the abdomen we find that it is distended, tympanitic, hard on palpation and tender. In the dependent parts, in the flanks, there is partial dullness testifying to the presence of free ascites which shifts its level when he turns on his side.

He also complains of painful attacks of diarrhoea—six or seven stools a day, and these attacks alternate with refractory constipation.

The liver does not come below the margin of the false ribs, but the spleen is enlarged and the liver is tender.

The legs are slightly œdematous over two-thirds of their surface.

Analysis of the urine shows 1 gm. 25 albumen per litre. The urine is pale, frothy, scanty and contains 2.25 grammes of urea to the litre.

Turning to the circulatory apparatus we find that his pulse is hard and the arteries tortuous and resistant. The blood pressure oscillates between 250 and 150 mm. On auscultation we hear the systolic murmur of mitral insufficiency and the lowering of the apex shows ventricular hypertrophy. Lastly, we note undulatory movements over the cardiac region suggestive of pericardiac symphysis.

In the lungs there is partial dullness over the right base corresponding to slight effusion into the pleura.

This patient, as you see, presents a complex symptomatology—he is the subject of lead poisoning, he has heart disease, and he has kidney disease, but the predominant feature is the renal disease, to which the gravity of his case is due.

I may recall that in the course of his plumbic symptoms the patient had an attack of saturnine gout. This fact is interesting enough in itself to fix our attention, because instances of this form of gout are by no means common.

Now it is often a matter of difficulty to ascertain how a given patient has become the subject of Bright's disease. We find that he has renal disease, but the cause escapes us. In this case, however, the origin of the disease is as plain as possible—it is of plumbic origin. He has been handling lead ever since he was 16 years of age, and he has handled it in a particularly dangerous form, in that he had to manipulate white lead. He has had three attacks of lead colic, yet he has had no paralysis—the commonest manifestation of lead poisoning. Since, however, he has displayed another manifestation, vastly more interesting than radial paralysis—viz., an attack of gout localised in the left big toe.

Saturnine gout differs in no particular respect from ordinary spontaneous gout; its course and

its distribution are the same—in fact it only differs in respect of the cause. This patient does not come of a gouty stock, and he has not been a big meat eater. He had his attack of saturnine gout late in life—in fact only eighteen months ago. It came on suddenly and violently, just like ordinary gout, lasted a fortnight and then subsided, leaving behind it certain vague pains that recur from time to time.

Gout may be due to auto-intoxication or to hetero-intoxication, such as lead poisoning, but it is the same gout however caused. A patient who suffers from saturnine gout must therefore be described as having a gouty diathesis.

True spontaneous gout is rarely seen in hospital, simply because our hospital patients do not lead the lives of certain of our private patients, more particularly they are not addicted to a diet rich in meat. On the other hand, the over-fed, rich town dweller does not compensate for his carnivorous habits by adequate expenditure of energy in the shape of physical exercise.

But everyone who fails to burn up his food does not become gouty, because something else is required for the production of gout—viz., the uricæmic soil. Given this soil, then over-indulgence in meat and insufficient exercise will culminate in an attack of gout. The same remark applies to plumbism, which is a cause of gout on all fours with over-indulgence in meat. Plumbism, however, does not always cause gout; on the contrary, plumbic gout is quite exceptional.

Now, this patient was unquestionably predisposed to gout. We may safely assert that if his habits of life had taken the direction of over-indulgence in meat and in abstention from physical exercise he would have had gout quite apart from any lead poisoning. These cases of saturnine gout prove that the influence of a toxic cause such as lead will, in certain subjects, determine an attack of gout, and we are driven to the conclusion that there is a particular soil which predisposes to attacks of gout. Not everyone can become gouty. Plumbic intoxication may be the cause in one instance and over-feeding in another, but this action is only manifested in predisposed subjects.

Now, this patient, at first sight, does not appear to correspond to this description of predisposed persons, for he has lost weight though it is easy to see that he must have been at one time fairly corpulent.

His form of gout suggested an examination of the urine, and we found 1 gramme of albumen per litre. This albuminuria explains certain of his symptoms, such as his shortness of breath, his palpitation and the œdema of the legs. It also explains his headache, for this plumbic headache, which used to be described as a special symptom, is merely a sign of Bright's disease.

We found a heightened blood pressure and a little chloride retention as shown by the œdema. The blood serum contains 2 gm. 27 of urea per litre, so that he is azotæmic in the third degree. It is interesting to note that in September there was only 1 gramme of urea, so his azotæmia is evidently progressive. This point is of considerable importance, because on it turns the prognosis. In these progressive cases we must apprehend a fatal termination within a few months. With 1 gramme the prospect of life may be extended to eighteen months or two years.

Just as he is cardiac because he had acute articular rheumatism in childhood so he is renal because he has dabbled in lead ever since he was 16 years of age. His lead poisoning revealed itself by attacks of lead colic and saturnine gout.

As for treatment, this comprises a diet containing little salt and not much meat. He is to take gr. xv. a day of theobromine and m. xx. of tincture

of squill morning and evening. Theobromine, as you are aware, possesses valuable diuretic properties which, in this case, will afford great relief, but it is useless to disguise the fact that the outlook is unpromising, whatever treatment we adopt.

CHRONIC URETHRITIS, GONORRHOICAL AND POSTGONORRHOICAL: A PLEA FOR ITS CLOSER STUDY.*

By A. STRACHSTEIN, M.D.,

New York.

Attending Genito-urinary Surgeon, Har Moriah Hospital.

OF all affections in the domain of minor urology, that of chronic urethritis stands out pre-eminently as the one which is most trying to the skill and patience of the urologist. Ricord (1) advisedly stated that we know when a specific urethritis begins, but only the Almighty knows when it ends. It is astounding to find so large a number of patients who, for reasons to be considered hereafter, have passed into a chronic state, and because of failure to procure proper therapeutic measures, have become indifferent about their condition and have despairingly abandoned treatment.

My reasons for writing this paper are twofold: First, to arouse a deeper interest among urologists in the subject of chronic urethritis, and, secondly, to impress on the general practitioner that chronic urethritis is by no means a simple affection that will either take care of itself, or end in recovery by the aid of those who are not specially trained in this branch of medicine.

The necessity of the former reason for writing this paper manifests itself when we consider how few are the papers that are read at our section meetings and what lack of consideration is given to this widely prevailing affection. The latter reason—i.e., to impress on the general practitioner how serious a malady chronic urethritis is, will be well understood when we investigate the disastrous effects brought upon the community by improperly cured patients (2).

When is a case considered to be chronic? Casper (3) and others are of the opinion that when a case of acute specific urethritis does not show any tendency toward abatement at the end of the sixth week, it may be said to have passed into the chronic state.

Ætiology.—In order to have a clear understanding of the subject, it is advisable to consider the many ætiological factors that are in varied degrees responsible for this malady. These may properly be divided into causes of local and those of general origin. Among the latter, too irritating or strong injections used during the acute state prolongs the existence of the discharge and finally causes it to pass into the chronic state. It is not uncommon to find patients who have been advised by friends to procure protargol or similar salts, without the physician's prescription or directions for its use. The usual result is that they procure a solution which is from four to eight times stronger than would do good. Then there are patients who do not abstain from sexual intercourse during the course of treatment, because, as they put it, "things come their way" and it is hard to let them pass. Others say that the wife insists upon coitus irrespective of the outcome. The third group of patients of this class simply become freshly reinfected before the previous attack is eradicated. We frequently meet in the clinics patients who cease treatment and consider themselves cured as soon as the discharge is no longer visible at the external meatus, but to their

great disappointment they find that they have erred in their diagnosis and this manifests itself soon after their first indulgence in venery or in alcoholic debauchery. Physical exertion we found to be a repeated factor. Thus, patients whose occupation compels them to walk the greater part of the day or otherwise to be physically active, present invariably protracted cases. For instance, there are patients who get on well when under treatment and a cure is not far off until they attend a dance usually lasting into the early hours of the morning, with the usual effect of not only a setback in the progress of the case, but also of an involvement of the posterior urethra.

Misdirected treatment is perhaps more frequently the cause than all others causes combined (4). Patients are frequently advised to procure a hand syringe for anterior injections, but are not instructed as to its capacity. The result is that they usually procure one that is much too large. This brings about repeated trauma by dilating the acutely inflamed and infiltrated urethra. Intemperance and various debilitating constitutional diseases are among other causes of general origin.

The local causes are as follows: A *narrow meatus*. This condition exists in a large number of patients and its presence prevents free drainage of the continually formed pus in acute urethritis. *Phimosis*, on the other hand, makes it impossible for the patient to carry out proper injections. *Stricture* of the urethra, either congenital or acquired from previous attacks of urethritis, has the same effect as a narrow meatus and is a typical cause of persistency. The existence of a *soft infiltration in the anterior urethra* or a *lacunitis* as well as *patches of abrasion* of the mucous lining of the urethra, especially in the bulb, are further causes. *Paraurethral involvement*, particularly of the glands of Tyson, may prolong a case indefinitely. Finally, *involvement of the prostate* plays an important rôle in chronic urethritis and Casper states it to be responsible for eighty-five per cent. of cases (5).

Bacteriology.—The gonococcus is the underlying cause. When superficially lodged in the urethra it can be easily destroyed when brought in contact with any of the antiseptics at our disposal; but when it penetrates the mucosa into the submucous layer, or when it entrenches itself in any of the glandular annexa that directly communicate with the lumen of the urethra, then the urologist has no easy task to dislodge it. However, Neisser's diplococci appear to die out after a number of months or years and thus convert the gonorrhœal into a postgonorrhœal urethritis.

Secondary infection (6). In many instances the discharge and the filaments contain numerous micro-organisms, either alone or in association with the gonococcus. These are streptococci, staphylococci, bacillus coli, and frequently also a short, thick rod-shaped bacillus appearing in chains. There is a variety of mixed infection in which there exists some relation between the different germs in the sense that one precedes the other and prepares the soil for its fructification. Taking pneumonia as an instance, under the influence of the pneumococcus the pulmonary alveoli lose their epithelium, which is thrown off as exudate and serves as a medium for the tubercle bacillus or other pyogenic germ (6).

Keyes, after considerable study, came to the conclusion that the gonococcus does not live longer than three years in the male urethra (7). The frequency with which gonococci are found in chronic urethritis varies. Thus, Scholtz found them to be present in ten per cent. of cases, while Casper found them in five to six per cent. Brauser found gonococci in ten cases out of a series of 163 (8). I

* Read before the Eastern Medical Society, November 12th, 1915.

have found gonococci in the prostatic smear six years after the original infection and after a seminal vesiculotomy was performed for gonorrhœal seminal vesiculitis. It would be difficult, however, to state whether the patient was not continually reinfected from his wife at more recent dates, although she was considered to be well.

Infectiousness. The absence of gonococci in a scanty smear or in the filaments does not necessarily exclude their presence somewhere in the genito-urinary tract. As stated, they may be hidden in any of the glandular annexa. Hence it may be necessary to cause irritation of the urethra in order to bring the gonococci to the surface. This is brought about either by injecting into the urethra a strong solution of silver nitrate one to 1,000 or one in 2,000, or by the patient's liberal use of beer or other alcoholic liquor on the day prior to the examination. Coitus, while not recommended as a means of irritation, has the same effect in bringing some of the gonococci to the surface. Women who are affected with a latent form of gonorrhœa may not transmit the infection to men to whom they are indifferent during cohabitation, but when the act is performed with a male who pleases her and who is capable of arousing a strong orgasm, it causes a copious secretion of the infected glands, which thus empty their infected contents and expose the partner to infection. Smears of the prostate and vesicles are of paramount importance, not only for search for Neisser's diplococci, but also for pus cells and other micro-organisms. Finger's (9) teachings, which have been accepted by many renowned authorities, are of interest. He holds every case infectious so long as the smear shows the presence of numerous leucocytes, which is an indication that an active inflammatory process is still in progress, even though gonococci cannot be demonstrated. Finger further insists that the following examinations must be resorted to in order to determine the presence or absence of infection: *a*, Daily microscopic examinations of the smear and filaments for from two to four weeks; *b*, there must be absence of pus cells from smear; *c*, absence of gonococci from a provoked discharge; *d*, absence of pus cells and gonococci from the prostatic and semino-vesicular secretions.

Kopp (8) reported seven male patients who had been microscopically examined from sixteen to twenty-two times with negative results, yet all infected their wives soon after marriage. Finger and Tauton had patients in whom repeated examinations by all known methods failed to reveal the presence of gonococci, but soon after a single dilatation gonococci appeared in the discharge. The writer has had similar experiences. Patients affected with chronic urethritis frequently call at the office or clinic with a laboratory report in their pocket stating "negative for gonococci." The patient, as well as his family physician, accepts this to mean that he is free from infection, but the foregoing laborious investigations plainly show what a folly it is to give such an interpretation thereto.

Pathology.—The pathology of chronic urethritis can be best understood when traced back to the very incipency of the infection. When the gonococcus is lodged in the male urethra, it remains dormant for a time (incubation period). Then it begins to penetrate the epithelium of the mucous membrane, working its way into the submucous coat. The leucocytes begin to extravasate by diapedesis from the blood-vessels of the invaded tissue and travel toward the surface of the urethra, and at once a combat begins between them and the gonococci, thus causing a purulent discharge which consists mainly of numerous dead leucocytes having

in their body substance many gonococci. Incidentally the irritation caused by the gonococcus and its toxins brings about a round cell infiltration into the submucous coat, and it is at this point that we reach the parting of the ways. If the acute urethritis goes on toward recovery, regeneration takes place with absorption of the infiltrated cells. If, however, for any reason the irritation persists and the case passes into the chronic state, then the round cell infiltration becomes organised into a permanent structure simulating connective tissue with its usual property of contraction. This newly formed tissue undergoes further changes so that it ultimately resembles dense scar tissue, although not as a consequence of ulceration (10), but rather of hyperplasia. While the process is at first sub-epithelial only, later it penetrates deeper until it reaches the corpus cavernosum.

The intensity of the infiltration and the ultimate degree of contraction of the newly formed tissue are both responsible for the many other varied pathological changes that are found in the urethra. The shrinkage of this tissue around the lacunae pushes them outward toward the lumen or causes their complete atrophy by the surrounding pressure. Littre's glands undergo similar changes. The foregoing changes take place in the pars anterior, but the posterior urethra may undergo similar changes in addition to the following: The colliculus may become markedly enlarged and in many cases may contain numerous small vegetations so that it assumes a raspberry-like appearance. The ejaculatory ducts may become sclerosed at their openings on the floor of the prostatic urethra, causing mechanical obstruction to ejaculation, which explains the cause of sticking pain during that act. The ducts may, as a result, become transformed into numerous diverticula which do not empty themselves during ejaculation; the result is the occurrence of spermatorrhœa brought on with each defecation.

Diagnosis.—Since the failure to localise the focus of disease is largely responsible for the persistence of the lesion (11), it becomes self evident how important it is to determine the exact cause in each case. After a careful history is procured in reference to previous infections, as well as to the mode of treatment of the actual instance, the following examinations should be made.

1. The discharge. This should be repeatedly examined for, *a*, gonococci, *b*, other micro-organisms, *c*, leucocytes as well as their preponderance over epithelial cells. As pointed out above, one or two examinations with negative findings for gonococci should not be considered conclusive. A further search should be made after provocative measures had been resorted to, to bring on an artificial discharge. This can be accomplished by injecting silver nitrate solution one in 1,000 or one in 2,000 and the resulting discharge is examined from three to six hours later.

2. The filaments. The filaments should be spread out on a glass slide with the aid of a platinum wire, and after being properly stained, should be examined microscopically. One should look for leucocytes and gonococci. When they consist of epithelial cells, they may be considered as remains of a postgonorrhœal process.

3. The appearance of the urine is of considerable help, although filaments in the first glass and none in the second do not necessarily mean that the anterior urethra alone is diseased and that the posterior is free from disease. The various glass tests are so ably described in the standard works on urology, that we shall omit them here. Increased frequency will often point to involvement of the colliculus or the prostate, hereafter to be considered.

The meatus should be inspected as to its size and also whether Tyson's glands are involved. A meatus below 20 or 21 F. should be enlarged.

4. The prostate and seminal vesicles. After micturition the bladder is partly filled, either with boric acid solution or with oxycyanide of mercury one to 5,000, preparatory to rectal exploration of these organs. But beforehand, the patient is instructed to pass part of the solution for the purpose of irrigating the entire urethra so as not to contaminate the prostatic fluid about to leak out. The prostate is first palpated as to size, shape, and consistence. It may be enlarged and tender, but a normal size does not exclude the presence of prostatitis. One side may be dense or nodular, while the other may be soft and boggy. Normally the seminal vesicles are not palpable, but when chronically inflamed they may be felt like tortuous cordlike bodies running along the lateral sides of the prostate. The prostate and vesicles having been massaged, a microscopic stained smear is now examined for pus and micro-organisms. Schlingenteit introduced the following macroscopic method of distinguishing between prostatic fluid, seminal fluid, and pus. Normal prostatic fluid disseminates and gives an opalescent appearance to the water, pus sinks to the bottom, and seminal vesicular fluid floats or hangs in the water.

5. Urethral localisation of focal lesions. Having exhausted the foregoing methods of examination, a further search for the cause becomes necessary, since the possibilities for persistence of symptoms are numerous. The aids at our disposal are, *a*, bougies and sounds, *b*, the urethroscope. The bougie-à-boule is of undoubted value as an aid to determine the existence of constricting bands in the urethra or the actual presence of strictures. When resorting to its use, we should select the largest size that the meatus will admit, and note is made as to the size which meets with obstruction as well as the size which passes through, and also the distance of the constriction from the external meatus. The shoulder of the acorn on the bougie-à-boule will show the presence of constriction as it is withdrawn from the urethra. Palpation of the urethra on a sound will frequently reveal periurethral local infiltration or local tender spots, but for these the urethroscope is of more value.

Urethroscopy.—By the proper interpretation of urethroscopic findings, we have at our command an aid of great service to pursue the further search of pathological lesions in the urethra. In the anterior urethra, exploration should be made for, *a*, soft infiltrations, *b*, hard infiltrations and constrictions, *c*, glandular changes, *d*, local denudations.

Soft infiltrations.—When the urethroscopic tube is inserted there may be a tendency to capillary bleeding. The mucous membrane appears considerably hyperæmic and in certain locations like the bulb the epithelial lining may be lacking and replaced by easily bleeding granulations. The pale-white striations observed in a normal urethra are not visible and the lumen, instead of being centrally situated, is displaced toward one side, showing bulging folds of infiltrated mucous membrane. While the openings of Littré's glands may not be visible, the lacunæ of Morgagni are dilated and choked with a visible drop of matter.

Hard infiltrations.—The tube is not easily admitted, the mucous membrane appears pale and presents into the lumen of the tube several thick folds of mucous membrane, but when the process goes on to stricture formation, these folds will no longer be visible. The glandular openings are barely visible.

The posterior urethra.—This part of the canal may show similar pathological changes with additional ones in the colliculus. This structure un-

dergoes changes in many instances, as described under pathology. These changes may be found in cases of non-gonorrhœal origin, and may be due to such causes as masturbation or excessive venery, as is shown in a case detailed by me in a recent article (11).

THE COMPLEMENT FIXATION TEST.

Since the reaction is dependent upon the presence of gonorrhœal anti-bodies, a positive reaction cannot be expected until a sufficient time has elapsed for their development—three to four weeks. Cases that become strictly localised in the anterior urethra do not become positive at all (12).

It must be borne in mind that a negative reaction does not have the same value as a positive one. This test has shown that from ten to twenty per cent. of cases that were considered clinically cured, are still infected (12). Does a positive reaction mean that there still exists a focus of living gonococci somewhere in the body; or that gonorrhœal anti-bodies may persist for a long time after all gonococci are dead? Schwartz and McNeil think it is due to recent activities of living gonococci. A positive reaction has never been found in a non-gonorrhœal patient (13). Gonorrhœal vaccines, when injected, give positive results when the blood is tested.

GENERAL MANAGEMENT.

The general health of the patient should be looked after, since improvement along these lines will aid materially the local condition.

Local Treatment.—The fundamental principle in the treatment of chronic urethritis rests largely upon the nature of the lesion found. Pathology teaches us that this process is characterised by infiltrations that are followed by contractures of varying degree. The need of mechanical dilatation of the urethra therefore becomes apparent in order to bring about absorption of the infiltrate to restore the lumen as far as possible to its normal calibre. The question arises, when to begin the dilatation treatment. Neisser, Janet, and others of equal fame, hold the view that so long as there are gonococci or other micro-organisms demonstrable in the discharge, no instrumentation should be resorted to, and that their extermination should be accomplished by proper methods of irrigation before undertaking mechanical treatment. But as previously shown, the mere absence of gonococci from repeated smears is not proof positive that they are absent, hence Wossidlo thinks that in such cases one must trust to luck and start dilatations. He further states that he observed cases in which gonococci were scantily present in spite of persistent treatment by irrigations, but he caused their disappearance by starting the dilatation treatment, with general improvement finally resulting in cure. We had cases in which gonococci were not found at the end of the second dilatation, and the cases went on to recovery, but the third dilatation brought on a profuse purulent discharge containing numerous gonococci without reinfection from without.

Finger reports similar cases. The following rules may therefore be laid down as to when to begin dilatations:—

1. When repeated examinations show no gonococci.
2. When persistent irrigation treatment fails to remove the few lingering gonococci, especially when the urethroscope reveals the presence of focal lesions in the mucous membrane and when the clinical symptoms show no contraindications.

The extent of each dilatation will largely depend upon the condition of the mucosa as revealed by the urethroscope. If the mucosa is considerably congested, painful, and tender, the dilatation must be started at a low scale and ascend very gradually until the sensitiveness subsides. Should the ure-

thra, however, not be sensitive, we can, from the outset dilate up to No. 28 and in each successive dilatation, ascend the scale from one to two numbers. When hæmorrhage is brought on, it is best not to go higher at the next sitting than half a number, or else remain at the same point as at the previous dilatation—i.e., if the last dilatation was brought up to No. 28 and hæmorrhage occurred, we therefore do not go higher than No. 28 at the next sitting. The frequency of each dilatation will largely depend upon the reaction set up in each case. Should hæmorrhage arise, we must wait for about ten or fourteen days before the next treatment; but in cases where the reaction is mild, the dilatation may be resorted to once in eight or ten days.

The period to be expended on the dilatation treatment will be governed largely by the amount of improvement that follows and by the urethroscopic appearance of the mucosa. The type of instrument to be selected will depend upon the part of the urethra involved. The ordinary sound may be used for the entire length of the canal, and we can gradually rise in size up to a point where further sound dilatation becomes extremely uncomfortable or inadmissible by the external meatus. We therefore resume further treatment by the use of the Oberlander-Kollmann dilators. Meatotomy should be performed when the small meatus proves to be a hindrance to the treatment.

Since dilatation causes mechanical emptying of the glandular sinuses of their infected contents, it becomes apparent how important it is to irrigate the urethra and remove these contents. With this object in view, Kollmann has constructed his dilator in such a manner that irrigation can be done simultaneously with dilatation. When this cannot be carried out, the urethra should be irrigated immediately after each dilatation, using an antiseptic solution such as silver nitrate one in 10,000 to one in 3,000 according to the sensitiveness of the patient, or a solution of oxycyanide of mercury one in 5,000. The irrigations must also be carried out independently of the dilatation treatment, and are best done every second day. Their purpose is to overcome the chronic catarrhal process of the mucous membrane superficially situated, and to stimulate healing of the denuded epithelium here and there. For this purpose our time-honoured drug, silver nitrate, heads the list of all those that are of benefit. It should at the outset be used in weak solutions, one in 10,000 to one in 6,000, and gradually raised in strength.

As the largest number of cases involve the whole canal, it is therefore wise to apply the irrigation to its entire length in the following manner: The patient is instructed to urinate and then, through a soft rubber catheter of moderate size, about 150 c.c. of the solution is injected, either with a Janet syringe or with the irrigator, and then he is told to urinate. When the case is still in the subacute state, we may first use the organic silver salts and then turn to silver nitrate.

When the lesion is confined to the anterior urethra irrigation can be carried out by inserting a soft rubber catheter into the urethra as far as the bulb, but when the posterior urethra is the main offender, good results will be obtained by the instillation method with the Keyes-Ultzmann instillator of 0.5 per cent. silver nitrate. In the extremely obstinate and stubborn cases where silver nitrate does not bring about the desired effect, copper sulphate three to five per cent. instillations will frequently give admirable results, but the patient should be warned of the sharp reaction and extreme discomfort that may last for several hours.

As stated above, the prostate is frequently involved, and unless this gland is attended to the

urethritis will continue indefinitely. Hence a systematic course of massage must be added to our other treatment and should be performed once in about five days. As the prostate may harbour in its glandular sinuses various micro-organisms, it becomes apparent how important it is either partly to fill the bladder with some antiseptic fluid which is to be voided immediately after the massage, or to irrigate the entire urethra soon after massage.

As a general rule, a chronic urethritis case requires treatment at least every second day, each kind of therapy at the following interval: *a*, Massage once in about five days; *b*, dilatation once in about eight to ten days; *c*, irrigations every second or third day. This scheme must, of course, be modified according to the amount of reaction that sets in, or according to indications that may arise. In cases where the smear or prostatic secretion shows secondary infection, the use of oxycyanide of mercury, one in 5,000, is beneficial, but its use is not to be recommended when the patient takes internally the iodides as the two seem to combine to produce mercuric iodide.

Urethroscopic treatment.—Urethroscopy is an unusually valuable aid in the treatment of chronic urethritis, but its use must be combined with all other means at our disposal (14). While in acute cases its use is contraindicated, yet in chronic urethritis it will most frequently clear up persistent cases. For instance, a case that was regularly and persistently treated for many months, still retained the morning drop and shreds. The urethroscope revealed the presence of denudation of the epithelium in the bulbous urethra, which was covered with minute granulations. The area was touched up with silver nitrate, ten per cent., on a swab through the tube on three occasions with the result that the shreds and morning drop disappeared. Another persistent case showed the lacunæ of Morgagni choked with drops of pus. These were touched up in the same manner with a favourable outcome. I recall two cases that were operated on for seminal vesiculitis, the first, three years ago, and the second, five years ago. After the seminal vesiculotomy, the urine was never clear, but was always moderately cloudy and contained heavy *débris* and shreds in spite of long treatment at two different clinics. Posterior urethroscopy with the Wossidlo urethroscope revealed to me in both cases exactly similar findings. There was a distinct pocket-like sinus in the prostatic urethra leading into the prostatic substance. By pressure with the finger in the rectum considerable *débris* was expressed from the sinus, enough to becloud the field of vision. These fistulæ, in connection with other treatments, were cauterised once in eight days with silver nitrate, twenty per cent., through the urethroscope with ultimate recovery in both. Similar therapeutic measures are beneficial in cases where the colliculus is enlarged and contains many vegetations which continually throw off shreds, aside from the fact that such a lesion causes urgency of micturition as well as sexual irritation. Furthermore, polypi and other foreign growths in the urethra can be treated successfully only through the urethroscope.

CORRESPONDENCE.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE MEDICAL PROFESSION AND THE ARMY MEDICAL SERVICE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg to enclose for publication in your next issue copy of correspondence with Sir Alfred Keogh, D.G.A.M.S., and having regard to the urgent and important matter with which it deals I hope you will be able to give it an important place in your JOURNAL.

I am, Yours truly,

MAURICE R. J. HAYES, Hon. Sec.,

Dublin, Irish Medical War Committee.

March 11th, 1916.

Sir Alfred Keogh, D.G.A.M.S.,
War Office,
London.

March 9th, 1916.

DEAR SIR,—I am directed to enclose for your information editorial comments in reference to the Central Medical War Committee appearing in the current issue of THE MEDICAL PRESS. I am particularly to direct your attention to paragraphs five and six, on page 206, in which it is stated:—

"That neither the one nor the other of these responsible and well-informed officials" (Sir Alfred Keogh and Mr. Tennant) "sees any present need for increasing the existing number of officers in the R.A.M.C."

"On the one hand we know on unimpeachable authority, that the Director-General does not want any more medical officers, a fact which, on the face of the numbers enrolled, must be perfectly obvious to any thinking person."

As my Committee is about to send a circular to the Irish doctors somewhat similar to that which has been issued by the Central Medical War Committee to the practitioners in Great Britain, the Committee, before doing so, would like to have information as to the accuracy of the statements above referred to, since, if they be true, the Committee would not feel justified in asking the Irish doctors to make the very great sacrifices which the volunteering of their services would entail.

As you are perhaps aware, the work of my Committee has been fruitful in procuring a very large number of doctors for service with the troops, and at the present time applications are being received in plentiful numbers. The Committee is of the opinion that since THE MEDICAL PRESS enjoys a large circulation in Ireland, the statements now appearing in it will tend seriously to interfere with the further recruitment of Irish medical men, and before taking any further steps to procure more men it is anxious to be reliably informed as to what the existing needs may be.

I am, Yours faithfully,
(Signed) MAURICE R. J. HAYES, Hon. Sec.

War Office,
Whitehall, S.W.

March 10th, 1916.

MY DEAR SIR,—The sentence which you quote from THE MEDICAL PRESS AND CIRCULAR is evidently founded upon some information which has been conveyed to that publication by some persons who do not take the trouble to understand the position. I think it is a great pity that the Editor, who must be a member, I suppose, of our profession, has not done me the courtesy of asking how the matter stands. It is not my custom to withhold information from any member of the medical profession who desires to receive it. The statement is entirely false. It is very far from anything I have ever said. There is no present necessity for increasing the number of doctors with the Armies abroad; but it is not fair to those patriotic men who have given us their services for a year that they should not be relieved by others who have, up to the present, done nothing. I want to get the names of all the medical men upon my list, so as to be able to relieve those who are abroad. You know that the medical profession is the only body of citizens which is only asked to serve for one year with the Armies. All others serve for the duration of the war. It is obvious that after the first year, the monthly additions up-to-date will require, month by month, relief, and when I tell you that the number of medical men returning from France, either sick, wounded, or compelled by the exigencies of their practices not to renew their engagements, amounts to over 150, it is quite clear that I require 150 doctors a month to replace them. The statements which I make to this effect are plain and intelligible to the meanest comprehension, but they are garbled by certain persons to suit their own views and to mislead many members of the profession, as they have obviously misled the Editor of THE MEDICAL PRESS AND CIRCULAR. A public official cannot reply to remarks appearing in the press, but this custom does not prevent him replying to private communications received from other people. In my opinion, the Editor of the paper could have ascertained how the matter stood without depending upon information conveyed to him by third and interested persons.

You are liberty to make any use you like of this letter.

Yours very truly,

(Signed) ALFRED KEOGH.

Maurice R. J. Hayes, Esq., F.R.C.S.I.,
Hon. Sec., Irish Medical War Committee,
c/o The British Medical Association,
16, South Frederick Street, Dublin.

["Sinapis," who is responsible for the paragraph referred to in the above correspondence, deals with this matter in the "Periphery" page.—ED. M.P. and C.]

IS GONORRHEA A BLOOD DISEASE?

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—With reference to Dr. McWalter's letter in your issue of March 15th, may I call his attention to Abel Soupplet's "La Blennorrhagie Maladie Générale" (Paris, 1893), and Marcel Sée's "Le Gonocoque" (Paris, 1896) (with bibliographies), wherein he will find much interesting matter?

As to chancroid, that may at times lead to an extensive serpiginous ulcerating condition of the skin lasting for years and very rebellious to treatment. I agree with Dr. McWalter that one should never make light of the chancroid sore. Chancroids should be treated just as carefully as any other

venereal infection. A sharp look-out should always be kept for the subsequent development of a primary syphilitic sore on chancroids. I have never had to regret a non-committal attitude from this point of view when in the presence of chancroids. It should also be borne in mind that chancroids may occur extra-genitally just as primary chancroids do.

I am, Sir, yours truly,
GEORGE PERNET, M.D.

London, W.
March 18th, 1916.

THE ROYAL COMMISSION ON VENEREAL DISEASES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The investigations of the Royal Commission on Venereal Diseases have thrown a strong light upon the disastrous effects of this scourge on the life of the nation. They have also shown that these diseases can be successfully combated and in time eliminated by the prompt application of the methods of modern medical science. But this achievement, which would put an end to an immense amount of misery and suffering, and would powerfully operate in increasing the efficiency of the population and in relieving its financial burdens, can be accomplished only by the action of the Government in providing the necessary facilities for treatment and by the spread of knowledge among the medical profession and the general public.

The National Council for Combating Venereal Diseases was formed in order to secure the fulfilment of these conditions, and it has already, by inaugurating lectures and in other ways, sought to draw attention to the grave danger which exists, and which will, as all experience proves, be greatly intensified when the war ends.

We desire to secure the co-operation of all bodies which are engaged in work directly or indirectly connected with these diseases, and especially to impress upon county councils and municipal authorities the necessity for helping in the dissemination of sound knowledge and plain warning.

The National Council proposes now to organise a comprehensive educational campaign to combat venereal diseases in all suitable ways, and especially along the lines laid down by the Royal Commission. This will involve the organisation of a number of conferences and courses of lectures, and the immediate issue of an authoritative summary of the principal conclusions of the report. These and other measures will need financial support, and we earnestly hope that all who realise the vital importance of combating diseases which are gravely impairing the national vigour and inflicting heavy loss of potential population, will be willing to assist our efforts.

Communications can be made to the honorary secretaries.

We are, Sir, yours truly,

SYDENHAM, President of the Council.
THOMAS BARLOW, Chairman, Executive Com.
LEONARD DARWIN, Treasurer.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, JANUARY 28TH, 1916.

The President, F. CONWAY DWYER, M.D.,
P.R.C.S.I., in the Chair.

A CASE OF ECTOPIA VESICÆ TREATED BY TRANS-PLANTATION OF THE URETERS.

MR. H. STOKES read a paper on the above.

The patient, aged about 25 years, had been brought up as a male, but a systematic examination proved that she was a female. The case presented the usual bulging patch of inflamed mucous membrane situated between the widely separated pubic bones. The umbilicus was absent. The external genitals were cleft. The vagina was represented by a funnel-shaped passage with a small opening in the normal situation.

Operation.—The ureters were isolated for about three inches, a rosette of bladder mucous membrane being left attached. Through a transverse incision the abdomen was opened and the uterus removed. The ureters were drawn in succession into the rectum, into which the rosettes projected freely. For three weeks the patient did well, and was able to keep herself quite dry. She subsequently developed signs of septic absorption, the end of the right ureter having sloughed, a fistula formed through the vagina. Ascending infection took place. Three months later an attempt was made to anastomose the right ureter into the colon through a flank incision. This proved to be impossible on account of the ureter being inflamed and attached to the vena cava. The right kidney, which was infected, was removed, but the patient died. A *post mortem* examination showed that death was due to ascending infection of the remaining kidney, which was due to an abscess which had formed outside the rectum around the transplanted right ureter. The autopsy further showed that the anatomy of the pelvic organs was normal, with the exceptions of the curious vagina and an internal displacement of the right ureter, which may have been caused by the first operation.

CONVENIENT RADIUM EMANATION TABLE FOR THERAPEUTIC PURPOSES.

Captain WALTER C. STEVENSON, R.A.M.C., read a paper, illustrated by lantern slides, on the above. He showed that the average quantity of emanation employed during a treatment could be directly read off the table instead of resorting to the troublesome expedient of a series of multiplications. The table shows the hourly decline in activity of 1,000 millicuries of emanation till in 12 days 19 hours it reaches 100 millicuries. Since the table contained over 300 numbers, the hourly loss of emanation corresponding to any one of these numbers could be similarly traced. If the amount of radium emanation available does not correspond to a figure on the table, it must correspond with the next lower figure within an hour. The decline of activity of 100 millicuries can be followed by starting again at the beginning of the table and inserting one place of decimals. For clinical work the convenience of the table for recording and estimating the dose was obvious. (This paper will be published in an early issue of THE MEDICAL PRESS AND CIRCULAR.)

CHEILOLOGY FOR THE RELIEF OF CRIPPLING ARTHRITIS OF THE HIP AND OTHER JOINTS.

Mr. W. I. DE C. WHEELER read a paper on the above. He pointed out that reference to these cases under the reading of traumatic was incorrect. The so-called "rheumatoid" arthritis was probably metastatic arthritis like all other non-traumatic inflammations of joints. He recorded a case, and showed X-ray photographs of a young patient operated on in October, 1912, for crippling arthritis of the knee and hip. The patient had been a cripple for seven years, and locomotion was only possible with difficulty and with the aid of crutches. Extension of the left knee-joint was impeded by lipping of the outer margins of the tibia and femur, and no weight could be borne on the right limb owing to the presence of a ring of osteophytes at the junction of the head and neck of the femur. Abduction of the leg was impossible. The operation of cheilotomy was performed on the left knee, and was followed a week later by removal of all the osteophytes from the right femur. There was a line of cleavage between the new and old bone. The relief was immediate, and the result perfect. When the wounds were healed the patient walked without crutches and without pain, and had full movement of both joints. X-ray photographs taken nearly three years afterwards showed no tendency to recurrence of the disease. This, Mr. Wheeler stated, was the first case of cheilotomy on record. He drew attention to similar cases in older people where there was no line of cleavage between the old and the new bone, and expressed the opinion that the operation of cheilotomy in such cases might be followed either by new formation of bone or complete ankylosis of the joint. In certain cases, where pain without the formation of osteophytes was the main feature, relief could be obtained, especially in young people, by removal of the colon. He mentioned a recent case which he had treated by colectomy. It was remarkable that chronic arthritis of the "rheumatoid" variety was associated with auto-intoxication from a static colon, and in such cases the operation of partial colectomy was followed by admirable results.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD MARCH 3RD, 1916.

The President, DR. LEONARD DOBSON, in the Chair.

Mr. J. G. PARDOE read a paper on
PROSTATITIS: ACUTE AND CHRONIC.

Having first described the anatomy of the parts concerned, Mr. Pardoe discussed the causes, symptoms and treatment of acute prostatitis. Heroic treatment, unless an abscess formed, was deprecated, the treatment recommended being hot irrigation of the rectum through two tubes. If abscess formed, and required opening, it should be opened through the perinæum, and never through the rectum, otherwise a troublesome fistula would probably result. Passing on to the subject of chronic prostatitis, Mr. Pardoe said that the key to successful treatment was prostatic massage and posterior irrigation, systematically employed. The treatment was described, and the investigations to be undertaken before a patient suffering from gonococcal infection of the prostate could be pronounced free from disease and allowed to marry. Tubercle and syphilis of the prostate were discussed. The differential diagnosis between adenoma carcinoma and fibrous prostate brought a most interesting and

practical paper to a close. It was discussed by the President and Mr. ASLETT BALDWIN.

Dr. S. D. CHIPPINGDALE showed a spleen, weighing less than two ounces, from a man æt. 73, who died from heart disease and bronchitis. The specimen was sent to the pathological laboratory for examination.

NEW LONDON DERMATOLOGICAL SOCIETY.

MEETING HELD THURSDAY, MARCH 9TH.

DR. ALFRED EDDOWES in the Chair.

CASES:—

DR. VINRACE: *Psoriasis*.—The patient, a man about 40 years of age, noticed a lesion on one foot about nine months ago, and for five months he had what looks like psoriasis. He has not had any itching, smarting or burning. Attention was called to the raised edges of the lesions.

DR. G. W. SEQUEIRA regarded it as a case of lichen planus in the form which often resembled psoriasis. But the border of the patches in this case was characteristic of lichen planus papules. It was interesting to hear that this patient did not suffer irritation.

DR. T. P. BEDDOES and the PRESIDENT expressed agreement with Dr. Sequeira.

DR. VINRACE replied that patches in psoriasis could be so like those of lichen planus that they seemed practically indistinguishable. He could not understand a statement being made in books that lichen planus was never generalised; he had seen several generalised cases.

(1) *Lupus erythematosus* of three years' duration, affecting chiefly the nose. In 1914 the upper half of the nose was treated with CO₂ snow in Scotland by two experienced dermatologists. A London dermatologist advised her to go to bed for three months, holding out great promise of good result. She regrets having taken that advice, as neither nose nor general health was in any way improved thereby. When first seen by Dr. Eddowes there was a scar occupying the upper half of the nose—thin and very white. The unusual whiteness was rendered the more conspicuous by reason of the redness, swelling and crusting of the spreading disease around it. Now, as is seen, the disease has practically disappeared. No fresh spots have formed and the white scar is assuming a flesh colour under the present treatment. Briefly stated, the treatment has been—internally, chloride of quinine; extraction of several teeth which were loose with pyorrhœa and thorough attention to the mouth. Locally: scarification, puncture, cautery, and soothing, antiseptic lotions.

DR. VINRACE remarked that Dr. Eddowes' treatment was efficacious. There could be risk in the snow, but not in scarification. When the snow was applied to persons with a poor circulation, a frost-bite sometimes ensued.

DR. G. W. SEQUEIRA thought the application of CO₂ was capable of doing much harm in acute cases; it was only in the chronic scaly cases that its effect was found to be good.

DR. EDDOWES replied that it was a risky form of treatment to apply CO₂ snow over the bridge of the nose, as the skin there was thin, and easily affected by cold. The skin being tight and thin, there was very little circulation between it and the bone. When he cut into the scar he was anxious to prevent a quick healing; he stretched it with his fingers so as to ensure the formation of new granulation tissue. Already there was a very great

improvement through the formation of new capillaries.

Dr. VINRACE: *Lichen hypertrophicus* in a woman æt. about 60. She presented herself at the polyclinic seven years ago, and Sir Jonathan Hutchinson diagnosed the condition as lichen hypertrophicus. The case was now brought to show the tendency for recurrence to ensue in the same patch of skin. After about 14 months' treatment it disappeared for about seven years. She has some enlarged veins in the leg.

Dr. G. W. SEQUEIRA agreed that this was a case of that form of lichen planus termed lichen hypertrophicus. The patch on the leg appeared to be quite typical. One of the features of lichen planus was its tendency to recur.

Dr. MACK agreed with the previous speakers. He had not seen a case of the kind in private since he had been in practice.

Dr. BEDDOES said these hypertrophic cases were nearly always due to congestion, and were seldom seen unassociated with varicose veins.

The PRESIDENT advised support by bandage. Varicose veins, if bandaged night and day, were capable of recovering the function of their valves, and would thus get well frequently without operation.

Dr. VINRACE replied that he wished to emphasise the fact that in recurrence the same patch of skin took on the same appearance as before, and in the same proportions. He would have her leg bandaged and suitable remedies applied.

Dr. EDDOWES: (2) A case of *lichen spinulosus* which had been shown to the Society four months ago was now brought on account of the appearance of fresh lesions—typical lichen planus. The patient now shows side by side *L. spinulosus* around and lying in a confluent lichenised patch with lichen planus a few inches away. Such a case is convincing proof of Dr. Eddowes' contention, which he has maintained for many years, that they are only different manifestations of one and the same disease. The modifications are chiefly due to the anatomy of the skin in the region affected, and partly to the effect of friction by clothing, etc.

Dr. G. W. SEQUEIRA considered the case one of typical lichen spinulosus with lichen planus. It was well known that the two conditions were often associated. He recently had a case almost exactly similar, affecting the back of the neck; there was a patch of lichen spinulosus surrounded by papules of typical lichen planus.

Dr. EDDOWES replied that in many books lichen spinulosus was separated from lichen, and spoken of as a keratosis. It was not really a separate disease. It was practically important to recognise this fact in treatment, as lichen would not tolerate strong remedies.

Dr. MACK said he could confirm the President's remark, because in one case of lichen planus under his care he treated it with Unna's plaster, of carbolic acid and mercury. The patient had a pain-taking wife, and she cut out pits of plaster and placed them on every papule. By mistake, the dispenser once sent salicylic plaster. There was acute reaction, but happily the whole of the lichen planus disappeared after one application.

THE PRINCESS ROYAL will open, on March 17th, the Active Service Exhibition at Prince's Skating Club and Knightsbridge Hall in aid of the British Red Cross Society.

SIR FRANCIS HENRY LOVELL, F.R.C.S., LL.D., Dean of the London School of Tropical Medicine, and formerly Chief Medical Officer at Mauritius, and Surgeon-General of Trinidad, left £2,140.

SPECIAL REPORTS.

ARMY MEDICAL ADMINISTRATION.

In the course of a debate in the House of Commons on March 15th, Mr. R. McNeill called attention to the administration of the Army Medical Service, and complained that immediately on the outbreak of the present war, the Government scrapped and threw aside the whole organisation which had been most carefully devised after the South African War. The advisory Board, which formed an important part of that organisation, and which was endowed with very considerable powers, was brushed aside and had never met since the war began. Terribly evil results followed. The functions of the Board were usurped by one man, the Director-General, Sir Arthur Sloggett. Indicating the radical unsoundness of the present organisation, the hon. member pointed to the basing of the Army Medical Service on the division as its unit as inconvenient and cumbersome. In mobile warfare the combatant unit might be proper, but in the present warfare the unit should be nothing smaller than the army corps. Dealing with details, the hon. member alleged wrong selection of sites for hospitals at Ypres, and the unnecessary retention of doctors on duty for thirty, forty, and fifty consecutive hours. At Loos thousands of wounded men were left lying in the open for many hours because the hospitals were full and the staffs overworked, although there were hundreds of doctors in another division within a few miles doing nothing. He did not blame the doctors, but the organisation which was utterly unsuited to the conditions. With our present system, rapidity in submitting wounded patients to operations, if operations were necessary, could not be secured, and a very large proportion of the injured soldiers who arrived in this country had wounds in a septic state. There ought to be movable hospitals all along our fighting front. Another point: the medical talent in the country was not used for the benefit of the Army as fully as it might be. A very large body of highly-instructed medical men held the views which he had tried to put before the House.

Major Astor said he was associated with a pretty large hospital, and had seen the landing of wounded men from the front, and he did not think that matters were quite as black as Mr. McNeill would have the House believe. He complained that unfit men, who were passed for the Army by overworked medical men, were kept in the Service after their presence had been disclosed. Hundreds of thousands of these unfit men were kept nominally for home defence, who were, in fact, wholly incapable of undertaking military service of any kind. This led to an unnecessary demand on the public funds.

Captain Amery agreed with Mr. Astor with regard to the enlistment of the unfit. He had been told that during the past year the number of such men, who were a sheer waste, was something like 200,000. The Prime Minister said the annual cost of the soldier was £250. If that was so we had wasted in that way alone fifty millions of public money. This was no new mess with which the Government was confronted. It was a mess which had been a whole year coming about. It was the result of trying to maintain a sham system of voluntary recruiting.

Mr. Long (President of the Local Government Board) said a question had been asked about the wounded in Mesopotamia. Nobody more than the Government deplored that there should have been any avoidable suffering, and nothing would be left undone to provide a remedy. Some weeks ago the Secretary for India (Mr. Chamberlain), who was laid up by indisposition, decided in conjunction with the Viceroy and the Commander-in-Chief in India, to send Sir William Vincent and General Bingley to Mesopotamia to conduct an inquiry into the medical arrangements there and take all possible steps to remedy deficiencies. Moreover, the War Office had supplied the Indian Government, who were responsible for the medical care of the Mesopotamian Force, with two Indian general hospitals and their complete personnel, with the personnel of two other similar hospitals, with one British stationary hospital containing 400 beds.

one British general hospital with 1,000 beds, 100 doctors, and 100 orderlies. In addition the War Office had offered to meet any further demands. The doctors were supplied about a month ago. With regard to the discharge of the unfit from the Army, there was no doubt that men unfit for foreign service had been enlisted and accumulated at home, and the Committee over which he presided had the subject under consideration. By getting rid of the unfit and putting accepted men into the right places, a deal could be done for useful recruiting.

Colonel Arthur Lee said a very strong and unfair attack had been made upon the medical arrangements of our armies in the field by Mr. R. McNeill. He felt bound to repudiate some of the grosser charges levelled against the reputation and record of the Royal Army Medical Corps. It deserved praise and credit from the people of this country. As Lord Kitchener's personal representative, he had reported upon the work of the corps in the field. For nine months he carried on his investigation, and he utterly failed to recognise in the harrowing tale Mr. McNeill gave, the faintest degree of correspondence with the facts as he saw them. Mr. McNeill was large-hearted and sympathetic, and he had been misled. So far from there being any complaint of the way in which the wounded were dealt with from the firing line to the base, there was nothing but gratitude and praise. In fact, the Royal Army Medical Service, like the Commissariat, stood out as a model of efficiency. He protested against the unjustifiable, violent, ill-informed, and baseless attack which had been made upon a body of as highly-skilled and gallant men as ever served the State. They deserved not censure or carping criticism, but the whole-hearted gratitude of the entire community.

OBITUARY.

SIR CHARLES BENT BALL, Bt., F.R.C.S.,
LIEUTENANT-COLONEL, R.A.M.C., REGIUS
PROFESSOR OF SURGERY IN THE UNIVERSITY
OF DUBLIN, HONORARY SURGEON TO H.M.
THE KING IN IRELAND.

THE death of Sir Charles Ball occurred at his residence, 24, Merrion Square, Dublin, on the 17th inst., after several weeks' illness. He was sixty-four years of age. Sir Charles Ball was a native of Dublin, being a younger brother of the late Sir Robert Ball, the astronomer. He was educated at Trinity College, Dublin, where, after a distinguished student course, he graduated B.A. in 1871, and M.B. in 1872. He studied for a time in Vienna. He became a Fellow of the Royal College of Surgeons in Ireland in 1879, and in 1900 he was elected an Honorary Fellow of the Royal College of Surgeons of England.

Except for a short time spent as a young man in general practice in Wales, his entire professional life was spent in his native city. His first public appointment was in the poor law service, and for several years he was dispensary doctor for one of the city districts. While still a young man he was appointed one of the surgeons to Sir Patrick Dun's Hospital, and this position he held to the time of his death. Some twenty years ago, he was appointed University Anatomist, a post of honour but without duties attached. A little later he became Regius Professor of Surgery. For the past ten years he was representative of the University of Dublin on the General Medical Council. In 1902 he was Lane Lecturer at San Francisco, and in the following year Erasmus Wilson Lecturer at the Royal College of Surgeons. He was knighted in 1903, and created a baronet in 1911. Soon after the war broke out, he was appointed consulting surgeon for the troops in Ireland with the rank of Lieutenant-Colonel in the Royal Army Medical Corps. For many years Sir Charles Ball took much interest in the Royal Zoological Society of Ireland, of which society he was president for a term. He was also for many years a member of Council of the Royal College of Surgeons in Ireland, though he was unsuccessful in his candidature for the Vice-Presidency. He was

President of the Royal Academy of Medicine in Ireland from 1909 to 1912. He held many positions as consulting surgeon in Dublin, to the following institutions, among others, Dr. Steevens', the Orthopaedic, the Dental, and Monkstown Hospitals.

Sir Charles Ball's chief surgical interest was in rectal surgery. His little book on "The Rectum and Anus, their Diseases and Treatment," of which the second edition appeared in 1894, had a great vogue in its day. In 1908 he published a work on "The Rectum: its Diseases and Developmental Defects," and he contributed articles to Sir F. Treves' "System of Surgery" and to many journals. He was not, however, a prolific writer, never writing without having something definite to communicate.

For many years Ball may be said to have occupied the leading surgical position in Ireland. None of his contemporaries in Ireland was so well known outside Ireland, and indeed few British surgeons had a wider fame. Of this his selection as Lane Lecturer is sufficient evidence. He was an ingenious and sound operator, and more than most surgeons he was able to take a wide view of a case. His interest in science was not confined to surgical matters. He was well read in all branches of natural science and was a keen field botanist.

He leaves a widow, two sons, and four daughters, to whom we offer sincere sympathy in their bereavement. His elder son, Mr. C. Arthur Ball, who succeeds to the title, is a member of our profession and surgeon to Sir Patrick Dun's Hospital.

DR. THEODORE THOMPSON, C.M.G., M.A.,
M.D., D.P.H. London.

DR. THEODORE THOMPSON, late assistant medical officer of the Local Government Board, died on Monday, at Oxford, at the age of 59. He was educated at Aberdeen and Edinburgh Universities, graduating M.A. at Aberdeen in 1877, and being admitted a licentiate of the Royal Colleges of Physicians and Surgeons, Edinburgh, in 1883. In 1884 he took the M.B. degree at London University. He was called to the Bar at the Middle Temple in 1894. About the year 1886 he was appointed medical officer of health for Aberdeen, and held that important position for about 18 months. On being appointed to a similar post in Sheffield he resigned the medical officership of Aberdeen. While in Sheffield he was called upon to deal with a serious outbreak of smallpox, and the experience he gained in that connection brought him prominently under the notice of the Local Government Board. Dr. Thompson was an inspector of the Board from 1891 till 1911, when he was appointed assistant medical officer. He prepared for the Board a number of reports which are highly prized by the profession, dealing with smallpox and other forms of zymotic disease, and in this branch of medical investigation he was a recognised authority and expert. In 1900 he was a member of the Committee of Inquiry into the Public Health of Dublin, in 1903 British delegate to the International Sanitary Conference of Paris and Plenipotentiary to sign the International Sanitary Convention, and in 1904 delegate to the West Indian Inter-Colonial Sanitary Conference, Barbadoes. He was nominated a C.M.G. in 1905 for services in connection with sanitary matters under the Foreign and Colonial Offices, and the following year visited Rome as a British delegate to the International Sanitary Conference there, and Plenipotentiary to sign the Convention, and was sent on a special mission of inquiry into the sanitary defence of the Persian Gulf.

DR. THOMAS UNDERHILL, M.D., J.P.,
WEST BROMWICH.

By the death on March 10th of Dr. Thomas Underhill, of West Bromwich, there passed away one of the oldest and best known men in the public life of the Black Country.

Dr. Underhill, who two years ago, was made an honorary freeman of West Bromwich, died at his residence at the advanced age of 92.

Alderman Underhill was born at Tipton on February 3rd, 1824, his father being Dr. Thomas Underhill, who practised as surgeon in that town. Educated

privately, and subsequently studying at the Birmingham School of Medicine and at Queen's College, he qualified M.R.C.S., L.S.A. in 1845, L.R.C.P. Edin. in 1859. In 1871 he became M.D. of St. Andrews, and when his father retired from professional work, he, with his brother, Dr. William Underhill, continued his practice in the Tipton and Great Bridge district.

Dr. Underhill was one of the pioneers in the movement for the erection of the Dudley Guest Hospital, and for sixteen years one of its honorary surgeons. In 1873 he removed to West Bromwich, and at once began to interest himself in the public work of the town. He became a member of the Board of Commissioners, and on the incorporation of the borough in 1882, was elected one of the first aldermen, while he became the second occupant of the mayoral chair. He served as a member of the Board of Management of the West Bromwich District Hospital, and was one of the oldest county magistrates in Staffordshire.

Dr. Underhill was a past president of the Birmingham and Midland branch of the British Medical Association, and for some years was a member of the Council of the Medical Institute in Birmingham.

When Alderman Underhill celebrated his golden wedding, the opportunity was taken of showing practical appreciation of his long public service by the presentation of a cheque for £1,000, contributed by his many friends throughout the district.

DR. G. G. PHILLIPS, M.R.C.S., L.S.A., TICKHILL.

DR. GEORGE GRIFFITH PHILLIPS, of Tickhill, near Rotherham, died suddenly on Wednesday, at the age of 76. Qualifying M.R.C.S. and L.S.A. in 1860, he had been in practice in the district for fifty years, and was appointed Medical Officer to the Doncaster Union in 1867.

DR. WILLIAM M. RAE, M.B., Ch.B., GLASGOW.

THE sudden death is announced of Dr. William M. Rae, who practised in the Crosshill and Govanhill districts of Glasgow. He was at work on March 10th, but was taken ill and died at a late hour in the evening. Dr. Rae was a Glasgow man, and a graduate of Glasgow University. He is survived by Mrs. Rae and two daughters.

MEDICAL NEWS IN BRIEF.

Sir Alfred Keogh's Assistant.

THE Secretary of the War Office makes the following announcement:—

Surgeon-General W. Babbie, V.C., has been appointed to assist Surgeon-General Sir A. Keogh, Director-General Army Medical Services, especially in the work of supervision of invaliding and all questions connected with the physical fitness of the troops at home.

The reports circulated in various newspapers to the effect that Surgeon-General Sir A. Keogh has resigned are quite untrue.

Surgeon-General W. Babbie, V.C., was educated at Glasgow University, where he graduated M.B. in 1880. In 1881 he joined the Army Medical Service. He served in Crete in 1897-8 as senior medical officer, and received the C.M.G. for his services. In 1899-1900 he served in South Africa on the Staff of the P.M.O. in Natal. He was mentioned in despatches and promoted to lieutenant-colonel. He received his V.C. for his gallantry at Colenso in attending to the wounded under fire, and also for going out and assisting to bring in Lieut. Roberts, who was lying mortally wounded. He became assistant Director-General, Army Medical Service, and then in 1906 was Administrative Medical Officer, Woolwich District. Later he held the appointment of Inspector of Medical Services.

Indian Medical College for Women.

THE Lady Hardinge Medical College for Women, in which the late wife of the Viceroy took so great an interest, was opened on February 18th.

The Viceroy explained that every possible attention

would be paid to considerations of religion and caste. The hostels have separate blocks for Christian, Hindu, Mahometan, Sikh, and Parsee students, with special dining-rooms and kitchens and everything else required to observe caste distinctions, while there is a general recreation room.

The College contains a central amphitheatre, a hall and library, with excellent laboratories and many lecture rooms. It has accommodation for 100 students, while the hospital has 150 beds and the training school will take 25 fully qualified nurses, with the same number of probationers. The dispensary and hospital for the treatment of out-patients has been built by subscribers in the Punjab. Three bungalows are already built for the women professors. One special feature is the division of the hospital into units, each complete in itself, containing family wards for separate accommodation, two general wards, two small separate wards, and a central building in each unit for purposes of administration. Thus each professor will have her separate and complete clinique with her own clinical laboratory, demonstrations and consulting rooms.

Blood Stopping Extraordinary.

DURING the hearing of cases of assault, drunkenness, etc., at Castlebar Petty Sessions, last week, Sergeant Hawkins told of a new method of blood stopping which was adopted by one of the parties. One Joe Conroy got a good beating and was bleeding profusely, and a man named Madden was trying to stop the flow of the blood. He had a long cloth round Conroy's neck, and then pulled the two ends tight, and then put his boot against Conroy's chest and pulled. He remarked to the sergeant that there was a vein in the back of the man's neck, and that he would stop the bleeding from it. The Chairman (Mr. Larminie) said he wished there had been a medical man there to see that new method. Answering a remark of the Chairman's, District Inspector Hogan said he hadn't Madden up for that as his intentions were good.

Exemption Tribunals.

AT Spring Gardens an appeal was made by Messrs. Hardy and Son, surgical boot-makers, of Wandsworth and Balham, for the exemption of Frederick H. Hardy, twenty-four, manager of one of the businesses. Mr. Hardy explained that the firm did work introduced by half the doctors in the district, as well as military work, there being only one similar firm in the south of London. His son made the patterns and lasts for the boots and outworkers were employed, some as far away as Northampton. He had tried other persons, but had given them up in despair.

The appeal was dismissed, and, on being informed that he could not make further appeal, Mr. Hardy exclaimed: "It is a very great injustice, gentlemen."

Liscard Central Hospital.

IT was stated at the annual meeting of the Liscard Victoria Central Hospital that the year had closed with a deficit of £2,340, as compared with £1,348 the previous year.

According to the report, four more members of the medical staff, including two resident surgeons, had joined the colours, and it had been very difficult to fill their places. War service had also claimed the hon. secretary. A gratifying feature was the increase of payments by patients, which was the best tribute possible to the attention they received. The in-patients numbered 1,108, and the out-patients 3,072, and there had been 667 surgical operations.

Medical Officer Indispensable.

AT a meeting of Hitchin Rural District Council, on March 8th, the chairman stated that with regard to the circular letter from the Local Government Board having reference to the release of medical men of military age, at the present time they must admit that Dr. Macfadyen, their medical officer, was indispensable to them. Dr. Macfadyen had also been appointed medical officer to the isolation hospital, and, as they were aware, the hospital was getting full.

In supporting the chairman, Mr. Ball said over-

crowding at Letchworth was something appalling, and consequently there was a great risk of disease. They knew there were two cases of enteric, and it was only by constant watchfulness on the part of the medical officer that some great outbreak would be prevented. Overcrowding, of course, would be mitigated when the 100 cottages in course of erection were completed, but even then it would not by any means be done away with altogether. He certainly thought it necessary that the services of the medical officer should be retained.

The Council acquiesced.

Medical Exemption from Military Service.

AT Bath Local Tribunal last week, Dr. Andrew Mackay Niven, aged 34, asked for present exemption owing to the fact that his partner, Dr. Heathcote, was on active service and he was doing two men's work to enable him to go. He was responsible for 2,000 panel patients and the same number of private patients. When his partner returned, he was willing to accept, if offered, a temporary commission in the R.A.M.C.

The Recruiting Officer was prepared to mark this as a certified occupation, and the certificate was issued so marked.

Shortage of Doctors.

SIR FRANK FORBES ADAM, presiding at the annual meeting of St. Mary's Hospitals, Manchester last week, spoke of the difficulties caused by the call of the Army for doctors. The shortage of doctors, he said, was becoming a serious matter for the hospitals, and had it not been for the patriotic devotion of the staff, who worked day and night, they would not have been able to carry on the work of the hospitals. Further calls on doctors should not be made unless absolutely necessary.

Grants from King Edward's Hospital Fund.

It is announced that hospitals in the County of London or within nine miles of Charing Cross, desiring to participate in the grants made by King Edward's Hospital Fund for London for the year 1916, must make application before March 31st, to the hon. secretaries, 7, Walbrook, E.C.

Anthrax from Shaving Brush.

A GAS inspector has died in Sheffield from anthrax, contracted from the bristles of a shaving brush while shaving himself. At the inquest a doctor said he knew of several cases of anthrax among soldiers three months ago due to infected shaving brush bristles.

Great Northern Central Hospital.

AT the sixtieth annual meeting of the Great Northern Central Hospital, Holloway Road, on March 16th, Mr. J. L. Smithett, who presided, said that their chairman, the Marquess of Northampton, was at the front, and over 50 members of the staff were now serving with the forces. During the year 626 wounded soldiers had been treated at the hospital and there had only been five deaths, although many cases were of a serious character. In the out-patient department 1,200 soldiers had been treated, many belonging to the Islington Battalion. Meanwhile, civilian patients had not been neglected, and last year there were 2,942 in-patients, 445 more than the previous year, and 23,115 out-patients. The total income of the hospital from all sources was £24,748, and the expenditure £24,300. This was the Diamond Jubilee year of the hospital and in normal times they would have made a festival of it, but in the present circumstances it was impossible to do so. In view of the increased cost of provisions and drugs the hospital was in need of a large income.

Maltese Hospitals' Record.

A MINUTE issued by the Governor of Malta, Field-Marshal Lord Methuen, to the Director of Medical Services, announcing a reduction in the hospitals, states that 60,300 patients have been treated in the Malta hospitals since last May. The number of beds

had been increased from a few hundreds to 20,000, and within one month, accommodation could be provided for 25,000 patients. His Excellency says he thinks that in no English hospitals could the patients have received abler treatment and greater care, and he lays stress on the help rendered by the philanthropic associations, the Ladies' Committee of the Order of St. John, and the British Red Cross, the local concert parties, and the people of Malta, including the Marchese Scicluna and the Casino Maltese. The patients' orderly conduct is attributed to the admirably organised concerts and amusements in the hospitals and camps.

The Late Mr. Stanley Boyd's Will.

MR. STANLEY BOYD, F.R.C.S., Surgeon to Charing Cross Hospital, has left £32,646. He left his estate in trust for his mother and sister, and subject thereto he gives £2,100 to Epsom College, for one foundation scholar, and the ultimate residue to the University of London for a Professorship of Pathology in the Medical School of Charing Cross Hospital. Out of the property belonging to his late wife he gives a number of legacies to her relatives, and £1,000 each to the London School of Medicine for Women, New Hospital for Women, and the Pathological Dept. of the New Hospital for Women, and any residue to the New Hospital for Women.

Royal Hospital for Chest Diseases.

THE Lord Mayor (Colonel Sir Charles Wakefield) presided, on March 15th, at the annual meeting of the Royal Hospital for Diseases of the Chest, City Road. He stated that since July last, the entire hospital had been devoted to the treatment of wounded soldiers. The sum received from the War Office was 28s. a week per occupied bed, but the actual cost worked out at 41s., leaving a deficiency of 13s. to be made up by the charitable public.

City of London Chest Hospital.

SIR GEORGE TRUSCOTT presided, on March 13th, at the annual meeting of the City of London Hospital for Diseases of the Chest. The report stated that the number of beds in daily occupation last year was 156, while 6,850 out-patients were treated. The Chairman said that up to the present time the beds set apart for wounded soldiers had not been used, but many patients had been received after discharge from the Army.

London Cancer Hospital.

PRESIDING, on March 13th, at the annual general meeting of the governors of the Cancer Hospital, the Earl of Northbrook said that at the outbreak of the war they decided to offer the use of their exceptionally well-equipped electrical and X-ray departments and fifty beds to the War Office. That offer was gratefully accepted, and during the past year fifty-seven soldiers had been admitted to the wards, and 135 military patients had received treatment in the electrical and radio-therapeutic department. It was satisfactory to know that a large percentage of the cases treated were restored to health and to active service.

Alleged Bogus Doctor.

AT Lawford's Gate Petty Sessions, on March 9th, Arthur John Partridge, 41, was charged that on December 23rd, at Kingswood, he made a false certificate relating to the death of Samuel Shipley Gane, of 91, Speedwell Road, contrary to the Perjury Act, 1911. Mr. W. S. A. Brown appeared on behalf of the Public Prosecutor, and asked for a remand, as there were at least five or six other charges of a similar nature, and a large number of witnesses had to be called.

Defendant told the Bench that he "practically pleaded guilty."

The information on which the warrant was issued stated that the defendant was formerly assistant to Dr. C. J. Perrott, of Kingswood, and attended a number of persons, and on their deaths gave the usual certificates. He was not a duly qualified practitioner, and it was alleged that there was only one

person named Arthur John Partridge registered as a medical practitioner, and he was at present serving with his Majesty's forces, and was not the Arthur John Partridge engaged by Dr. Perrott who signed the certificate referred to.

As it was necessary to bring Dr. A. J. Partridge from the front and to call other witnesses, the Bench remanded the defendant.

Consumption not Growing.

THE Lord Mayor of Leeds, presiding at the annual meeting of the Leeds Association for the Prevention and Cure of Tuberculosis, held on March 9th, stated that in combating consumption the Association was fighting a great enemy, and he was of the opinion that tuberculosis could be stamped out. This terrible disease was not growing in the country, and although victory was a long way off, it was certain to come if the Association carried on its good work. It was interesting to know that 200 patients were actually fighting, and that the war had done them no harm.

A Dutch Panacea.

At the Mansion House, on March 13th, the master and mate of a Dutch eel sloop pleaded guilty to a charge of selling medicine called "Dutch Drops" without a licence and without affixing a stamp.

Mr. Dart, representing the Customs, said it was claimed for "Dutch Drops" that they cured every ailment under the sun. The master sold them at 7d. a bottle, but the mate undersold him, and charged 2d. For the defence it was stated that the vessel was remaining in the Thames till after the war, and the men sold the medicine to get pocket money. Custom House officers and policemen were among their patients. They admitted bringing over some thousands of bottles.

The master was fined 20s. in respect of two sales, and the mate 40s. in respect of four. The fines were paid by the ship's brokers.

The Only Doctor Left.

ON February 28th, the Swansea Health Committee was called upon to decide whether to release Dr. Evans, borough medical officer of health, for service at the front. Dr. Evans had expressed his anxiety to enlist, but the chairman was strongly opposed to it. Another member said the point was who was going to suffer most, the men at the front or the people of Swansea for want of proper medical attention. He much preferred they should suffer. The chairman replied that they had to consider the future generation and added that if Dr. Evans enrolled, they would be losing not only mothers but children as well. He was the only medical man left for a borough of 94,000. By three votes to two the committee decided against the doctor enlisting.

Wounded Soldiers in Hospitals.

ON February 29th, Mr. Tennant, Under-Secretary for War, said that on February 12th, there were in military hospitals in London 2,437 wounded soldiers, in auxiliary hospitals 1,267, and in civil hospitals 578. In the military hospitals on the same date there were 5,346 vacant beds.

Army Mental Cases.

BARROW Guardians have passed a resolution urging the Government and the War Office to make provision for soldiers suffering from mental derangement, instead of sending them to ordinary lunatic asylums, to be maintained at the expense of the ratepayers and thereby pauperising soldiers.

Fire at Turkish Hospital.

A FIRE has occurred at the Hungarian Red Cross Hospital, Constantinople, where 352 severely wounded soldiers were being nursed. A panic occurred, but all were saved.

University of Durham.

THE following Candidates have passed the Second Examination for the Degree of Bachelor of Medicine during March:—

Anatomy and Physiology.—Honours, Second Class:

John M. Brydson, James R. Hughes, B.A.

Pass List: Sujan Raj Chatterji, Rev. Samuel Foskett, Ibrahim Giris, Samuel E. Goulstine, John P. Higham, David Levinstein, Habib Toma, Hans W. Walther, George R. Woodhead.

Anatomy.—Iris M. Cheeseright, B.Sc.

Royal College of Surgeons of Edinburgh.

At the recent dental examinations just concluded, the following candidates passed the first dental examination:—Edward C. Smith, Erstine L. Kelly, Meindert de Villiers, Oscar U. G. Reinocke, John Sharpe, Nico H. Albertyn and Cayetano Bathencourt, and the following passed in the subject of Chemistry and Physics:—Egbert J. C. Steyn, Gordon S. Richardson, Alexander Phillips, Andrew J. Molyneaux, Alan W. Hart and Mary C. Adam.

At the same diet the following candidates passed the final examination and were granted the diploma, L.D.S., R.C.S.Edin.:—William A. Rankin, Aubrey C. F. Barrow, George W. Young, Hamish M. Cranna, James L. Farnon, John F. Campbell, Douglas M. Mackenzie, William A. Mein, David C. Lamond, Johannes J. de Witt and Henry C. M. Morgan.

MEDICAL WAR ITEMS.

FOREIGN DECORATIONS.

It is announced in the *London Gazette* that the King has granted authority for the wearing of the following decorations:—

Insignia of the Third Class of the Order of the White Eagle (conferred by the King of Serbia): Captain E. N. Bennett, T. F. Reserve, for services as Commissioner in Serbia of the British Red Cross and Order of St. John.

Third Class of the Order of the Nile (conferred by the Sultan of Egypt: Mr. J. B. Christopherson, M.D., Sudan Civil Service.

Fourth Class of the Order of the Nile: Capt. A. G. Cummings, R.A.M.C.; Mr. V. S. Hodson, M.V.O., M.B., member of the Sudan Civil Service.

COMMENDED IN DESPATCHES.

THE undermentioned officers have been commended for service in action in despatches received from the Vice-Admiral Commanding the Eastern Mediterranean Squadron covering operations between the time of the landing on the Gallipoli Peninsula in April, 1915, and the evacuation in December, 1915—January, 1916:—

Deputy Surg.-Gen. Octavius William Andrews, M.B., R.N.; Fleet Surg. John Menary, M.D., R.N.

NOTICES TO CORRESPONDENTS, BREVITIES, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s. post free at home or abroad.

Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs Dawson and Sons are our special agents for Canada. For South Africa, The Record Publishing Co., Cape Town. Messrs. Geo. Robertson and Co., of Sydney and Melbourne, are our special agents for Australia.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Dr. W. J. MIDELTON.—Your communication reached us as we were "at press."

A DIETETIC CLINIC.

A DIETETIC clinic has been started at Buxton for the treatment of ailments of the stomach, intestines, kidneys, heart, and nervous system; and of arthritis, neuritis, gout, rheumatism, obesity, constipation, and high blood-pressure. The dietaries of Combe will be adhered to for colitis; of Dengler for digestive troubles; and of Van Noorden for diabetes. The Buxton Baths and Pump Room are within 3 minutes' walk from the clinic. Tariff and full particulars can be had from the Secretary, Dietetic Clinic, Buxton.

Dr. W. P. B.—Our correspondent's letter is a little dubious and lacking in an essential detail—namely, whether the bond was terminable after a stated number of years.

SLATES IN SCHOOLS.

In reply to a question on the threatened scarcity of paper for schools, Mr. Herbert Lewis says that the Board of Education would regard the reintroduction of slates as open to grave objection on hygienic and on educational grounds.

L.R.C.S.EDIN., M.R.C.S.—Five per cent. of glycerine added to eau de Cologne lessens the rapidity of evaporation.

MINERS' GIFT OF AMBULANCE.

ASHINGTON miners are making a levy upon themselves to provide a motor-ambulance for troops. The colliery owners will supply the necessary £600 in the first instance, and the men will pay it in instalments.

ESCLAPIUS.—Exposure to light and heat causes chloroform to deteriorate; chemical changes ensue under these circumstances, by which free chlorine is liberated, with irritating effects upon the patient. This would probably explain the trouble caused in the case to which our correspondent alludes.

ROAD-SWEEPER AS PLEASURE CAR!

THE Shoreditch Borough Council have purchased a couple of road-sweepers. The Customs officials now seek to mulct the authorities in duty amounting to £220, the ground assigned being that a road-sweeper must be classed as a pleasure car under the Finance Act, 1915.

SMITHFIELD (Honiiton).—It is stated that no fewer than 1,600 men from St. Bartholomew's Hospital and Medical School are serving in the Navy, Army, and Territorial Force.

WAR WORK FOR THE AGED.

AN old age pensioner earning 38s. 6d. at munition work for the year before was held by the Isle of Wight Commissioners as not entitled to a pension.

"AMBULANCE, PLEASE."

THE Post Office has agreed to accept without charge telephone calls for the municipal ambulances. Persons calling must say "Ambulance," and state where it is required.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 22ND.

ROYAL SOCIETY OF MEDICINE (SECTION OF OPHTHALMOLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Paper. Colonel Lister, A.M.S., and Lieutenant-Colonel Gordon Holmes, R.A.M.C.: Disturbances of Vision from Cerebral Lesions with Special Reference to the Cortical Representation of the Macula. Neurology.—Members of this Section are specially invited to attend the meeting of the Section of Ophthalmology (see above).

HUNTERIAN SOCIETY (1 Wimpole Street, W.).—9 p.m.: Annual Discussion.—The Relationship of the Medical Profession to the State and the Community (opened by Dr. F. J. Smith), Sir John Collie, Dr. T. D. Lister, Mr. L. Dodd, and others will take part in the discussion.

FRIDAY, MARCH 24TH.

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISEASE IN CHILDREN) (1 Wimpole Street, W.).—4.30 p.m.: Cases: Dr. E. A. Cockayne: (1) Scleroderma; (2) Paroxysmal Haemoglobinuria. Dr. E. B. Gunson: Gangrene of Leg following Diphtheria. Dr. J. L. Bunch: A Papulo-necrotic Tuberculide. Dr. H. Thursfield: Rickets: Multiple Fractures; and other cases. Specimen: Dr. J. D. Rolleston: Brain of "Mongolian" Imbecile. Short Papers: Dr. R. Hutchinson: Report on a Case of Hemi-hypertrophy with Post-mortem Examination. Dr. H. C. Cameron: Osteogenesis Imperfecta (Illustrated by cases and skiagrams).

TUESDAY, MARCH 28TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF PSYCHIATRY) (1 Wimpole Street, W.).—8.30 p.m.: A paper will be read by Dr. Bernard Hart on "The Psychology of Rumour."

Vacancies.

Putney Hospital (Chester Bequest), Lower Common, Putney, S.W.—Resident Medical Officer. Salary £150 per annum, with rooms, board, and laundry. Applications to the Hon. Secretary, at 198, Upper Richmond Road, Putney, S.W.
Bristol General Hospital.—Casualty House Surgeon. Salary £175 per annum, with board, residence, etc. Applications to Thomas W. Gregg, Secretary.
Nottingham City Asylum.—Senior Assistant Medical Officer. Salary £300 per annum, with apartments, board, and laundry. Applications to the Medical Superintendent.
The Guest Hospital, Dudley.—Senior Resident Medical Officer. Salary £150 per annum, with residence, board, and washing. Applications to the Secretary.
The Royal Surrey County Hospital, Guildford.—House Surgeon. Salary £150 per annum, with board, residence, and laundry. Applications to the Secretary at the Hospital.
Cambleshire Asylum, Fulbourn, near Cambridge.—Junior Assistant Medical Officer. Salary £200 per annum, with

board, lodging, washing, and attendance. Applications to the Medical Superintendent.

Boothle Borough Hospital.—Junior House Surgeon. Salary £170 per annum, with board, lodging, and laundry. Applications to the Secretary, 71 Oriol Road, Boothle, Lancs.

Hulme Dispensary, Dale Street, Stretford Road, Manchester.—House Surgeon. Salary £250 per annum, with apartments, attendance, coal, and gas. Applications to Honorary Medical Secretary.

Leeds Public Dispensary.—Lady Resident Medical Officer. Salary £130 per annum, with board, residence, and laundry. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

Appointments.

GILCHRIST, J., M.D., Ophthalmic Surgeon to the Victoria Eye Infirmary, Paisley.

LYSTER, R. A., M.D.Birm., D.P.H., Lecturer in Forensic Medicine at St. Bartholomew's Hospital

MERRICK, W. J., M.B., B.Ch.Dubl., Certifying Factory Surgeon for the Castleknock District, co. Dublin.

SIMPSON, H., M.B., District Medical Officer of the Tonbridge Union.

THACKRAY, ELIZABETH, M.B., B.S.Lond., Deputy Medical Officer to the St. Pancras Board of Guardians.

WATSON, S. J., M.B., B.S.R.U.I., Certifying Surgeon under the Factory and Workshop Acts for the Abercraze District of the county of Brecon.

Births.

ARMSTRONG.—On March 13th, at Greenbank, Latchford, Warrington, to Dr. and Mrs. E. Frankland Armstrong—a son.

DE ZILWA.—On February 2nd, at Villa Mireille, Ward Place, Cinnamon Gardens, Colombo, Ceylon, the wife of Lucian de Zilwa, M.D., B.Sc.Lond., of a daughter.

DUNCAN.—On March 16th, at 14 North View, Liverpool, the wife of Captain Thomas Duncan, R.A.M.C. (temporary commission), of a son.

FOWELL.—On March 13th, at Woodcroft, Kenley, Surrey, the wife (*née* Violet Hood) of Patrick Harvey Clive Fowell, M.D., of a son.

GUTTERIDGE.—On March 13th, at Northlands Road, Southampton, the wife of Temp. Captain B. G. Gutteridge, R.A.M.C.—a son.

HOLROYDE.—On March 12th, at Selby Lodge, Consett, the wife of Lieut. G. Holroyde, R.A.M.C. (Mlyn Garth, Windermere)—of a son.

MILNE.—On March 12th, at The Chestnuts, 9, High Road, Streatham, the wife of George Milne, M.D., D.P.H., of a daughter.

ORLEBAR.—On March 11th, the wife of Jeffery Alexander Amherst Orlebar, M.B., Pakyns Manor, Hurstpierpoint, near Brighton, Temp. Lieut. R.A.M.C., of a son.

PEARCE.—On March 17th, at Enfield House, Bury Old Road, Manchester, the wife of Dr. P. Leslie Pearce, of a daughter.

PRITCHARD.—On March 13th, at 1 North Road, Highgate, to Dr. and Mrs. Clifford Pritchard, a daughter.

STANISTREET.—On March 16th, at Weymouth, the wife of Fleet-Surgeon R. W. Stanistreet, R.N., H.M.S. "Endymion," of a daughter.

WARNER.—On March 16th, at Croydon, the wife of Thomas Warner, M.D., Temporary Lieutenant, R.A.M.C., of a son.

WILLAN.—On March 14th, at 23 Claremont Place, Newcastle-on-Tyne, the wife of R. J. Willan, M.V.O., F.R.C.S., Staff Surgeon, R.N.V.R., of a son.

YOUNG.—On March 15th, at Holly Bank, King's Heath, Birmingham, Helen, wife of Graham Pallister Young, M.B., B.S., M.R.C.S., L.R.C.P., of a daughter (Faith Biron).

Marriages.

BELL—AUSTIN.—On March 15th, at "Cardon," Mortonhall Road, Edinburgh, Francis Gordon Bell, M.D.Edin., F.R.C.S.Eng., Temporary Captain, R.A.M.C., only son of Mr. and Mrs. Bell, "Flaxmere," Marborough, New Zealand, to Marior Welsh Berry, elder daughter of Mr. and Mrs. Austin, Bank of Scotland House, Kilmarnock.

Deaths.

BALL.—On March 17th, at his residence, 24 Merrion Square, Dublin, Charles Bent Ball, Bart., M.Ch., F.R.C.S.

CHAVASSE.—On March 12th, of broncho-pneumonia, at No. 2 General Hospital, B.E.F., Captain Arthur Ryland Chavasse, M.B.Oxon., R.A.M.C., only son of Lady Chavasse and the late Sir Thomas Chavasse, of The Linthurst Hill, Barnet Green, Worcestershire, in his 29th year.

CAMPBELL.—On March 10th, at 18 Queen's Road, Southport, Colin George Campbell, M.R.C.S., etc., aged 63 years.

FERGUSON.—On March 10th, at a nursing home, Southsea, Colonel Richard Patrick Ferguson, late R.A.M.C., of 13, Spencer Road, Southsea, aged 76.

GAVIN.—On March 12th, in France, accidentally killed by a fall from his horse, Neil Murphy Gavin, F.R.C.S.EDIN., Temporary Lieutenant, R.A.M.C., Medical Missionary of the Irish Presbyterian Church at Anand, India, youngest son of the late Hugh Gavin, Stirling, and husband of Muriel Gavin, Coldara, Gerrards Cross, aged 42.

SHORTBRIDGE.—On March 9th, at his residence, Brookhill, Honiton, Devon, T. W. Shortbridge, M.D., aged 62.

THE MEDICAL PRESS AND CIRCULAR

AT THE PERIPHERY.

"Loué par ceux-ci, blâmé par ceux-là, me moquant des sots, bravant les méchants, je me hâte de rire de tout, de peur d'être obligé d'en pleurer."—BEAUMARCHAIS.

Committee of the Royal Colleges. THE announcement in the *Times* of Friday last that the Royal Colleges have combined to appoint an Advisory Committee to assist in the work of enrolling medical men, will be received not only with satisfaction but with a real sense of relief. I suggested the appointment of such a Committee in the "Periphery" of March 8th, and I am glad to find that the suggestion has met with so prompt and satisfactory a response. I pointed out last week that as soon as the members of the profession have real confidence in the body which is to decide the many delicate and complicated questions which surround the question of enrolment in individual cases, the reluctance which has so far been manifest will disappear. The appointment of this Advisory Committee is excellent. It will act as a Court of Appeal in whose judgments everyone will have confidence.

For Confidence. BUT excellent as the appointment of the Committee is, it must not for a moment be supposed that that is all that is necessary to put the matter of enrolment on a thoroughly satisfactory basis. It is good that there should be a reliable Court of Appeal, but that does not do away with the necessity for so reconstituting the Court of first instance as to make it thoroughly acceptable to the profession. At the risk of being accused of wearisome iteration, I repeat what I said last week on this subject—namely, that the Central Medical War Committee will not be acceptable to a very large section, and that by no means the least important section of the profession, so long as Dr. Cox and Mr. Bishop Harman remain as its secretaries, and so long as the Committee continues to meet at the offices of the British Medical Association in the Strand.

Laymen. I SEE that Sir Philip Magnus, in the House of Commons on Thursday last, suggested that the old Advisory Board, whose function it was to cooperate with the Director-General, should be reconstituted, and that the reconstituted Board should consist of some lay representatives. Sir Philip Magnus was understood to intimate that the proposal of lay representatives had come from

some members of the profession. Now, this is a matter upon which the ideas of the profession should be quite clear. It has been proposed that a layman accustomed to organising on a big scale should be appointed as assessor to the Director-General, to aid the latter in the onerous and difficult tasks which this war has imposed upon him. Such an appointment, if made, would automatically terminate when peace was declared. That is one thing. It might be a good thing or a bad thing; it is, at any rate, a totally different thing from having laymen on the permanent Advisory Board of the Army Medical Service. That the latter would be a thoroughly bad thing both for the profession and for the Service there cannot be the slightest doubt.

The Advisory Board. THE old Advisory Board was created immediately after the Boer War to enable the military authorities to bring themselves and keep themselves up to date on the purely medical side of their organisation. The R.A.M.C. officer, as soon as he attains the rank of major, relinquishes his professional work to become an administrator, and the higher he advances in military rank the further does he recede from "doctoring." Thus it comes about that the colonels and generals in the R.A.M.C. are very far from being practising doctors—they are overseers, organisers and administrators, whose knowledge of matters purely professional is necessarily both rusty and antiquated. To overcome this obvious and inevitable difficulty it was expedient that these functionaries should be kept abreast of modern thought and practice from among those who were still, so to speak, in the thick of professional and scientific work. They were, therefore, given an Advisory Board, whose members were still professionally active.

Its Powers. THE first Board thus appointed was endowed with very extensive powers. But, as the lessons of the Boer War came, gradually through its agency, to penetrate the reluctant receptivity of the War Office, the officials of the latter found that the pushfulness of the Board gave them too much to think, and the Board was soon deprived of

its erstwhile powers. Little by little these powers became whittled down, and at the outbreak of the present war the Board and its activities were frankly and incontinently "scrapped." Much may be forgiven to a department in times of stress, and I make no complaint that the War Office should have lightened its burden of inconvenient advisors in 1914, more especially as it seems to have shown itself eclectic in its methods by keeping the kernel while debarrassing itself of the husk. If anything now remains of the original Advisory Board it is a mere rump, both in power and personnel, which continues its existence at the pleasure of the permanent military authorities. Again, I make no complaint, so long as it is understood that all this is a temporary arrangement which will cease with the cessation of hostilities.

BUT we must look to the future.

The Lay Wedge. That the military authorities, whether combatant or medical, should have something in the nature of a free hand during the present crisis all

reasonable people are agreed. It is necessary, however, to guard ourselves against the thin end of a wedge which might claim that what is conceded in war-time shall be made a precedent for the establishment of restrictive or revolutionary methods in the coming peace-time. The medical department of the Army must, at all hazards, remain medical. It is already too much under the heel of the military. The Director-General himself is between the upper and the nether millstone, as witness his powerlessness in the matter of battalion Territorial medical officers; and if the Advisory Board is permanently deprived of its powers, or if its purely medical complexion is to be altered by the introduction of lay members, then the influence of the professional upon the medical side of the military arm will either disappear altogether, or it will become so impotent as to be entirely useless. So long as Sir Alfred Keogh occupies his present position this difficulty will not arise; but there can be no guarantee that his successor will be as loyal a supporter of the profession as he is.

AND, granted that a purely medical advisory board is to be reconstructed

Mandarins. after the war, there arises the all-important question of how it should be constituted. In working out his scheme for the Insurance Bill Mr. Lloyd George made the mistake of supposing that he would get the best advice from the plutocrats of the profession on a matter which concerned purely the rank and file, with the result that in several important details the Act was ludicrously defective. It is sincerely to be hoped that no such mistake will be made in the present case. Governments and departments are all too apt to suppose that all doctors are just doctors, that there is no line of demarcation between various kinds of doctors, and they imagine that, say, a President of the Royal College of Physicians of London, whose life has been lived between Harley Street and St. Bartholomew's Hospital, has a deep and intimate and sympathetic knowledge of the conditions of practice which obtain in a colliery district. They might as well act on the assumption that the

Lord Chancellor was acquainted with the circumstances surrounding legal practice in the slums of Birmingham. And yet when they are legislating for the many, they call to their councils only the representatives of the few.

THIS is a mistake which is in danger of being repeated, but it is **and Plutocrats.** one which ought not to be repeated.

If laymen are introduced on the Advisory Board at Whitehall, the governance of medical military matters will pass from the hands of the profession altogether. That governance, or influence, or whatever it may be called, in so far as it exists at all, is at present vested in members of a branch of our calling who know little or nothing about the trials and difficulties of the general practitioner—which is bad enough. But with the layman installed, worse is in store; for the medical element will be entirely swamped by the self-satisfied civilian element, which will probably be legal, as all our Government is depressingly and even debasingly legal. The medical profession must arouse itself to a realisation of this danger; it must insist upon being adequately represented on bodies which carry the future of its members in their hands. It must organise itself and become articulate. It must, above all things, make it quite clear that a few opulent and titled denizens of the purlieu of Cavendish Square are not its accredited representatives when such questions as the medical side of State services are under consideration.

WITH the appointment of the Joint **The B.M.A.** Committee of the two Royal Colleges of London and England the present pressing problem of recruiting the profession for military service passes **again.** into a new phase. The men who were justifiably backward in putting their domestic, financial and professional cards on the table for the inspection of Dr. Cox and Mr. Bishop Harman, of the British Medical Association, will feel that there is now an appeal from such tact, taste and insight as these two gentlemen may be capable of bringing to the discharge of their delicate duties. A semi-public enquiry into the conditions which surround every doctor of military age is at best an inquisitorial affair, and as such is highly distasteful to the vast majority. But distaste becomes accentuated into positive repugnance when the inquisition is to be conducted by self-elected persons with no particular reputation, either for judgment or discretion. In spite of the appointment of the Committee, the facts concerning each individual who enrolls will still presumably, in the first instance, have to pass under the eyes of these two gentlemen, so that their continuance at their posts constitutes a barrier to complete enrolment. Why do they remain? Why are they allowed to remain? If the scheme is to succeed, they must go. And the scheme ought to succeed.

THE Director-General has told us that to replace normal wastage he **Enrolment.** requires about 150 doctors a month. The problem of providing this number, with due regard to the interests of the civil population, is a serious but by no means

an insurmountable one. For the selections to be made with something approaching to equity between the various districts, and with fairness between man and man, the selecting body must obviously be in possession of all the available facts. In the hands of the Heaven-born, injustices would occur even with full data. Imagination reels at the thought of what will happen in the hands of a Committee which has the misfortune to be British Medical born, where it has insufficient data to work upon. It is therefore clearly the part of a public-spirited man to "do his bit" in providing data which are as nearly as possible complete. Enrolment does not necessarily mean that the enroller will be called up; but it does mean that the Committee will be in a position to judge so much the more fairly and impartially on the case of every man whose case comes before it.

THE case of the specialist is a very knotty one. On the one hand there

The Specialist.

is the fact that not very many of these, even if they be surgeons, are required at the front; and most of

the purely specialist jobs have a waiting list, which is already full to overflowing. On the other hand, it is clear that a specialist of over forty years of age, as, for example, a physician who has always been a pure physician, is of very little service to the military, whereas he is very important to the civil community. Such men, and specialists of other kinds, especially if they be on the staffs of hospitals, are not in the least likely to be displaced from their present employments, but they would nevertheless do well to send their names and circumstances in to the authorities. If they are not content to do this to the Central War Committee—a decision which would surprise no one while the present secretaries are in office—they can communicate with the newly appointed committee of the Royal Colleges or with the Director-General himself. The latter is the most accessible and least official of officials, and is always ready to give a sympathetic ear to personal difficulties.

SINAPIS.

MR. HENRY HINES LEE, of Kensington, left £250 to the Surgical Aid Society.

FIFTEEN soldiers are now segregated at the Fulham Military Hospital as "carriers" of cerebro-spinal fever infection. Two soldiers segregated as "carriers" have developed the disease in acute form.

HORNSEY TOWN COUNCIL has decided to point out to the Local Government Board that the Medical Officer of Health, Dr. Coates, could not be spared, and that his assistant left to join the Forces in the early days of the war.

A FIRM, on whose behalf it was stated that they were the only firm in the country to fit padded rooms in asylums, obtained from the Southwark Tribunal four months' extension for the only employee able to do that kind of work.

THE salary of Dr. G. Cohen, of Haringay, the Coroner for the Central District of Middlesex, has been increased from £190 to £375 by the Middlesex County Council. It was stated that the yearly average of inquests held during the past five years was 143 as against 112 for the three preceding years. Nine extra parishes were recently added to Dr. Cohen's district.

"THE GOLD CURE": PERENNIAL IF NOT PANACEAL.

WHETHER it was its peculiarly attractive lustre, its (formerly) unrivalled specific gravity, its unique resistance to the rusting powers of the atmosphere, its strangely refractory virtue of self-preservation when exposed to the usually overwhelming action of the higher-grade acid chemical solvents—or the combined influences of "suggestion" presented by the unparalleled aggregate—that conferred upon metallic gold the preternatural reputation which it possessed in past ages as a panacea for the relief of the ills, physical as well as mental, of humanity—singly and combined—remains a query to which no final answer can now be given. But the relapsing fever of its therapeutic investigation ever and anon reappears, and well shows that the primal faith in the wondrous possibilities of this medicament has by no means died out in the twentieth century, or been obscured by the shadowy gloom of the most destructive war known to the annals of the human race. Between alcoholic dipsomania and suppurative adenopathy there has always yawned a widely open gulf, yet the magical therapeutics of the precious metal was held by the collective clinical record of the opening years of this epoch to have bridged over the same with conspicuous success.

Let us take a preliminary backward glance at the opinions—believed in, or at least avowed—by "the highly experienced and famous chemist, John Rudolph Glauber," whose cognominal immortality has been secured by its association with the familiar sodium salt. The energies of that mighty mind were by no means confined to a single salt, or group of such, or even limited by the walls of his laboratory, for we find on inquiry that when he prepared his solution of "Green Lyon, or wonderful Golden Salt," he took his contemporary public into his confidence in the following printed announcement:—

"This Golden Liquor being drank, strengtheneth and confirmeth the whole humor radicale, Stomach, Brain, and all the inward parts of the body beyond all other medicines which I have hitherto known. Also it expelleth Melancholy, and all anxieties of Mind, taketh away Palpitation of the Heart, openeth obstructions of the internal vessels; it healeth the knots of the inward parts, as Liver, Lungs, etc., and cureth all inward exulcerations; it cureth Gravel and Stone, whether in the Penis or Bladder; it keepeth the Body soluble; expelleth Wind with the pains of the Cholick; preserveth the Blood from corruption; cureth the Leprosie, Scabs, and Fears of all sorts; in process of time it taketh away the Gout; to the insulting Apoplexy and Epilepsy it affordeth present cure; it cleanseth the blood infected by the Scurvy, Plague, and other Contagious Diseases; it preserveth and freeth from all internal Ulcers; defendeth the Lungs, Liver and other parts; and removeth Exulcerations already arisen; and takes them away radically. It so tingeth all the parts of a Man with its Balsamic Virtues, that not being easily obnoxious to Diseases, they enjoy a sound and long life. Outwardly used, it healeth all fresh wounds, no less than old and open Ulcers, without any Ointments or Plasters;

for in curing Ulcers of this sort, there is nothing in Animals, Vegetables, or Minerals, which answereth to this in Virtue; as also inwardly it cureth Rupures."

This vastly comprehensive statement of properties and powers would seem, at least at a first careless glance, to have left small room or opportunity for the discovery of new items of virtue in the domain of aural therapeutics by subsequent generations of clinical observers or laboratory experimentalists. Nevertheless, the "gold cure for dipsomania" which loomed rather largely over the medical horizon of the opening years of the present century almost seemed to indicate a still further expansion of the panaceal claims. (Possibly the fact that "it expelleth Melancholy, and all anxieties of Mind" may be utilised as an explanatory *rationale* of its successful antagonism to the dipsomania to which the unhappy so often have recourse for a corresponding purpose?)

Then we had, some dozen years (or thereabouts) ago, an announcement by a distinguished French physician, M. G. Bué, of the discovery that the general antiseptic properties of chloride of gold were fully equal to those of the most potent iodine compounds (then in prominent repute), and that its topical application betrayed a special predilection for attack on every juxtaposed habitat of that deadly enemy of the human race, the microbe of tuberculosis. In the treatment of local tuberculous lesions he used a solution containing one gramme each of chloride of gold and chloride of sodium in 50 grammes of distilled water. Aspiration of suppurating gland and evacuation of tuberculous osseous tissue were respectively followed by injection of 1 cc. of the gold solution, two or three times a week. The opening left by the needle was sealed with cotton dipped in collodion. From four to twelve injections caused, we were assured, local cure in every case, no untoward after-effects occurring in any.

In our present issue we have the clinical use of colloidal gold in rheumatic and allied conditions powerfully advocated by Dr. Grenet, of Paris, who furnishes a remarkable series of curative results in support of his thesis.

CURRENT TOPICS.

Conscientious "Objects."

A MOST amusing feature in the embroglio concerning recruiting is the sorry figure cut by so-called conscientious objectors in all parts of the country. Relatively these do not appear to have been very large in number. The absurdity of the pleas put forward at the Tribunals, in many cases, has properly brought about the discomfiture of the applicants and made them "objects" of ridicule. Cases have been recorded of individuals who would look on complacently while Huns assaulted their mothers or sisters! One man who evidently would not hurt a fly was engaged—at enhanced remuneration—making high-explosive shells, for others to fight with, of course. His conscience would not permit him to do the latter! At another Court an applicant was identified as a man who had sung "Your King and Country Need You" at recruiting meetings last summer. Now that the country

needs this "patriotic" singer his conscience is urged as an excuse for not doing himself what he urges others to do for him! Another of the "objects" supplemented his conscience plea by producing a medical certificate stating that he suffered from "acute attacks of ergophobia." The facetious Sheriff—it was a Scotch Court—translated this as "work-funk!" That the best-laid schemes of mice and men oft gang a-gley finds illustration in the case of a young man who appeared recently before a London Tribunal holding in his hand a large Bible. Said he, "I have received a call for the mission field, and am about to go to the Belgian Congo." He declared he would not render any assistance to a wounded soldier. The Court decreed that he should be trained for another "field" by refusing the appeal. Another unctuous body told the same Tribunal, when pressing his conscience excuse, that his "citizenship was not of his country, but of heaven." He was "here in the body only." To this the military representative is reported to have replied, "We will take your body, and leave the other part alone!" Complaint has been made of scant courtesy afforded to the super-conscientious at the Tribunals, and a letter has been forwarded on the subject from the authorities. In ordinary circumstances discourtesy cannot be defended. Those who clamour for exemption from service cannot complain, however, when the Court and public opinion regards the defences set up—of which the foregoing are only samples—as mere puerile piffle.

Pulse in Scarlet Fever.

OUR French correspondent informs us that Dr. Nobecourt, at the last meeting of the Society of Medicine, Paris, stated that in a series of scarlet fever cases he had observed that a certain time after recovery tachycardia was present. The latter comes on either without any appreciable cause or under the influence of some slight intercurrent infection or of an attack of rheumatism with or without cardiopathy. With the exception of the latter cause, there was no appreciable modification of the heart. The presence of tachycardia may be noted first thing in the morning, when the patient is still in bed, and in this case it is generally of the orthostatic type. There is neither functional or subjective trouble nor arrhythmia.

Army doctors ought to be aware of these cases, for men who present tachycardia need one or two months' convalescent leave, and when they return they ought to be carefully examined before a definite decision is taken concerning them.

Blood Transfusion in the Treatment of Hæmorrhage in the New-Born.

THE treatment of hæmorrhage by subcutaneous administration of serum is well established, as in a case of hæmorrhage in the new-born recorded by Dr. Mabel Crawford in our present issue. Untoward anaphylactic effects need not be feared, and the efficiency of the method is proved if only the dose be given in large quantity and in good time. There are, however, cases in which serum given subcutaneously will not suffice. Such are cases of internal hæmorrhage not recognised until the anemia is extreme; also cases where the loss of blood, though obvious, is so rapid that its arrest by this method will not save the patient from death. In such cases the transfusion of a suitable quantity of whole blood has been found to give encouraging results. In dealing with adults, however, the danger of hæmolytic is so great, and has proved fatal in so large a proportion of cases, that blood transfusion should very rarely be undertaken without a preliminary

investigation of the reaction of the blood of the donor with that of the recipient. This investigation must be carried out in a laboratory; it will take some hours, and may have to be repeated a number of times before a suitable donor is found. In dealing with hæmorrhage of the new-born we are more favourably situated. We have available a donor whose blood has been in intimate relation, has all but mingled, with that of the infant for many months. That the mother's blood may safely be transfused into the new-born child has been repeatedly proved in clinical practice, and has recently been further established by the investigations of Cherry and Langrock, of New York. They tested exhaustively the reactions between the bloods of mother and infant in 34 cases, and in no one of these was there any sign of hæmolytic or agglutination. They therefore claim that in every case of hæmorrhage in the new-born it is permissible to transfuse the mother's blood without any preliminary laboratory tests, thus rendering the procedure feasible under all circumstances where the condition of the mother permits, and with a minimum loss of time. They find it convenient that the blood be withdrawn from a superficial vein of the mother's arm and carried into the external jugular vein of the infant. It is of great importance that the blood should be transferred indirectly in order that the quantity used may be known, and 60—75 c.c. are said to be generally sufficient. The syringe and cannula method would seem to be best, it being a matter of choice whether the vessels are lined with a layer of saline, sodium citrate, or paraffin.

Fees.

FROM the land of the Almighty Dollar comes a strong and insistent recommendation to the profession to stiffen their backs in the matter of remuneration. Each visit is to be charged for at the full fee. In order to obviate any complaint upon the part of the patient, systemation padding is to be employed, such, for example, as recording of blood pressure, enumeration of leucocytes, and it is laid down that at all visits subsequent to the first "instruments of precision should be employed." Any mechanical apparatus for special treatment should be employed if possible. All therapeutics which entail the return of the patient are to be preferred to those which cause him to remain away—contented or not is not stated. The above scheme does not partake of very much exaggeration. We deplore and condemn such professional conduct. To increase one's income at the cost of mental equanimity is bad enough, but affords no comparison to such a sublime mixture of empiricism and dishonesty.

Discipline of the Wounded Soldiers in Hospital.

EVERYONE who has anything to do with the management of civil hospitals which are housing wounded soldiers must have been brought face to face with the difficulty of maintaining discipline. While the men are in bed or seriously ill the difficulty is slight, though even then the injudicious visitor, with his or her accessory supplies, requires careful watching. When the men are convalescent, however, and able to be up and out, the trouble begins. For the most part the men themselves are hardly to blame. Many of them are young and some are thoughtless, but on the whole they are decent, well conducted, and self-respecting men. But they are no sooner outside the hospital gate than temptation is thrown in their way. The average Englishman's idea of kindness is centred round the rite of "standing a drink," and, anti-treating orders

notwithstanding, drinks are somehow available. We do not suggest that more than a small number of wounded men drink enough to injure themselves, but it is impossible to maintain discipline in a ward with one or two half-drunk, or even a few elated men. That more serious events sometimes occur is shown by the report of the death a few days ago from acute alcoholic poisoning of a young soldier in hospital at Cambridge. The regulations necessary to prevent such occurrences as we have spoken of often appear harsh and unreasoning, and in the current number of the *Spectator* the writer who calls himself "A Student in Arms" makes bitter complaints of the inelasticity of hospital discipline. It is certainly foolish that when a soldier is debarred—perhaps rightly—from the visits of his own friends he should have to submit to the petting and impertinence of well-meaning and fussy society ladies. But, as the editor of the *Spectator* points out to his correspondent, there are sound reasons for most of the regulations of which he complains.

Gangrenous Rigidity.

DR. PRAH, at the last meeting of the Paris Academy of Medicine, called attention to a symptom, not mentioned in the textbooks, which he observed in five cases of gangrene among his war patients in Belgium. This symptom consists in the appearance in the affected limb of a muscular rigidity, more or less extensive, which gives to the limb the appearance of rigor mortis. He calls this symptom "gangrenous rigidity." It may be localised in one muscle (contracture of biceps) or affect a whole segment of the limb. Very probably the contracture spreads progressively, but the author was not able actually to observe this, for death or surgical intervention speedily put an end to the phenomenon. The rigidity can be overcome by a few forced movements. It is always a very serious symptom, and may be considered as foretelling fatal massive gangrene.

The Cause of Rheumatoid Arthritis.

FOR a long time rheumatoid arthritis was one of the puzzles of medical etiology. We spoke of it in a grandiloquent way, designed to cover our ignorance, as "a constitutional disease." But, of late years, evidence has been accumulating that rheumatoid arthritis is a disease due to bacterial infection. The frequent association with pyorrhœa alveolaris and with other foci of septic absorption is more than one of coincidence. Again, the marked effect of treatment by autogenous vaccines derived from whatever septic focus is present, seems to prove the dependence of the arthritis on bacteria. In our present issue we print a paper by Dr. Vipond, of Montreal, who has carried the matter a little further. He has succeeded in separating from the lymph-glands in a number of cases an organism, a vaccine of which produced remarkably good results. This organism, a diplococcus, he also found in the urine, and from his description, it appears to be similar to, if not identical with, an organism described in this country as present in the urine of such patients, vaccine treatment with which has given good results.

Cerebro-Spinal Meningitis.

THE report just issued by the Medical Research Committee, under the National Health Insurance Act, on "Cerebro-Spinal Fever during the Epidemic of 1915," brings together, in a clear and concise form, a great mass of very careful and well-planned work, done by many observers. The authors of the report are Prof. F. W. Andrewes, Prof. Bullock,

and Prof. Hewlett. The chief conclusions are important. That the "meningococcus" is indeed the specific germ of the disease, remains the sure foundation of the work. It is a true species, "as species go amongst bacteria." There are subspecies of it; but these ought none the less to be called meningococcus, not para- or pseudo-meningococcus. From this "specificity" of meningococcus it follows that bacteriological examination is the necessary method for a positive diagnosis of the case. The subject of the detection and treatment of "carriers" is carefully considered. It appears that even the most vigorous and varied treatment of the back of the throats of carriers may fail to rid them of the germs; the report is more hopeful of good results from "an open-air life and the provision of as much fresh air as possible." For the treatment of the declared disease, the specific antitoxin did not, in the adverse conditions of last winter, fulfil expectations: it did not achieve so much as it achieved in the Belfast epidemic of 1907, and in some American epidemics. It remains the only "rational" treatment; but cannot be put anywhere near diphtheria antitoxin in the records of the art of healing.

The R.A.M.C.

[*Mr. Tennant, Under-Secretary for War, said that a certain M.P.'s criticism of the R.A.M.C. was wholly unjustifiable, and ought not to have been made.—DAILY PAPERS.*]

Ay, man! Ha'e ye ta'en to the rollin' o' logs,
To sulk wi' the Simons and grunt wi' the Hogges?
Let me tell ye there's never a ginnin' M.P.
Fit to blacken the boots o' the R.A.M.C.

Ye'd fill up your lugs wi' the latest o' lees
'Gainst the lads who are savin' your skin overseas;
'Non-combatants?' Ay, weel, that just as may be!
Come ower, man, an' wark wi' the R.A.M.C.

Tak' haud o' a stretcher an' try it yoursel'
On a road that's been plastered wi' bullet an' shell;
If ye managed to bide there we'd maybe agree,
An' your tongue would be kept aff the R.A.M.C.

"Conscientious objectors" they're givin' us next,
Wi' bees in their bonnets a' bizzin' a text;
To the deil wi' their like! Ye can tak it frae me,
We're seekin' nae skunks in the R.A.M.C.

We're sick o' the gousin' political trade,
We're sick o' the Westminster mouthin' brigade,
We're sick o' the slackers wi' hearts a' a'gley,
But we're proud to belong to the R.A.M.C.

BRASSARD.

—From the *Westminster Gazette*.

The Hygiene of the Bedroom.

A FRENCH correspondent who has had some experience of "sleeping out" in both countries criticises the sleeping accommodation among the working and lower middle classes of society in England. While in French homes of the humbler class spare cash is expended in making the bedroom comfortable, in corresponding English houses it is the little-used parlour that attracts all the surplus. The bedroom furniture is "skimpy," the bedsteads are gaunt iron structures with comfortless wire mattresses that yield in the centre, hammock fashion. The mattresses, which are made of wool when not, indeed, not of coarse vegetable fibre, rarely ever of horsehair, are generally lumpy and uncomfortable—and no wonder, for mattresses in England are only remade when there has been a mishap or a death in the family. This is not only

inimical to comfort, it is also extremely unhygienic—witness the extraordinary amount of miasmatic dust that mattresses collect in the course of a few months' active service. In France, says our correspondent, even in the humblest home, mattresses are carded every year without fail. This process of renovation is usually carried out by an itinerary *mattelassier* in the yard or garden where he can be supervised to prevent his filching any of the horsehair or wool. His fee is five francs, and the operation takes a couple of hours in his deft hands. No such facilities are available in England, not even in London, where the charge for re-making a mattress would be from fifteen to twenty shillings. Moreover, the mattress has to be sent to a big firm where it is retained for a week or a fortnight and returned notably lighter than when it departed. It would indeed be remarkable, in view of the quasi-impossibility of effective control, if unscrupulous employees did not appropriate a few handfuls of valuable horsehair, as and when the opportunity presented itself. These drawbacks may account for the unpopularity of mattress cleansing in England and the consequent discomfort.

PERSONAL.

MR. R. R. LEEPER, F.R.C.S.I., has been appointed Consulting Visitor in Lunacy in Ireland, in the place of the late Sir Charles Ball.

MR. W. I. DE C. WHEELER, F.R.C.S.I., Dublin, has been appointed honorary surgeon to the forces in Ireland with the honorary rank of Major in the R.A.M.C.

DR. STAINTHORPE, the Medical Officer of Cleveland, has set a good example in these days of restricted imports of paper by issuing his annual report type-written on the back of old documents.

MR. EDGAR A. BROWNE and Dr. G. C. Walker have received the cordial congratulations of their professional colleagues on attaining their jubilee as members of the Liverpool Medical Institution.

SURGEON-PROBATIONER J. D. ARTHUR, R.N.V.R., one of the survivors of the wreck of H.M.S. Tara, who were captured by the Senussi, is reported by the Admiralty as having been rescued from captivity.

COLONEL CHARLES STONEHAM, C.M.G., F.R.C.S., senior surgeon at Westminster Hospital, left £24,865. He directed that his body should be burned, and the ashes cast in the sea, or scattered as widely as possible over the land.

DR. WILLIAM MORGAN, Swansea, was presented with an illuminated address testifying to his great popularity and usefulness, on his resigning the post of medical officer to the Great Western Railwaymen's Provident Society, which he has held for 21 years.

MR. GORDON O'NEILL, professor of obstetrics in the Peiyang Medical College, Tientsin, has been given permission by the King to accept and wear the decoration of the Seventh Class of the Order of the Excellent Crop, which has been conferred upon him by the President of the Republic of China in recognition of valuable services rendered.

THE LORD MAYOR has received from the Royal Waterloo Hospital for Children and Women, which reaches its centenary this year, an invitation to preside at a public meeting to be held in the City on April 27th to celebrate the occasion.

FRENCH CLINICAL LECTURE

ON

TREATMENT OF ACUTE ARTICULAR RHEUMATISM WITH
INTRAVENOUS INJECTIONS OF COLLOIDAL GOLD.

By M. H. GRENET,

Medecin des Hopitaux, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE first of the series of cases, of which the summarised record is here presented to the reader, is that of a patient (Obs. I.) who had been suffering from a malignant form of acute rheumatism. The approach of death appeared to be inevitable and rapidly nearing, despite the intensive treatment with salicylate of soda which had been adopted; when I administered an intravenous injection of colloidal gold. After the succeeding stage of rather violent reaction, the temperature subsided; on the following day it was normal, and never rose again. The patient thus entered at once on the stage of convalescence—retaining only the double mitral lesion which had developed under my own observation during the period in which he was undergoing the salicylate treatment. The very remarkable success thus obtained in a case which had almost been *in extremis* incited me to follow out a course of systematic trial of the same therapeutic process in the cases of other rheumatic patients.

The second of this series of cases which I have had under clinical observation was that of an infantryman who had been attacked by a form of rheumatism of medium severity. He was quite cured after a few days. The third case was that of a lieutenant, who had reached the sixth day of a serious attack of rheumatism, presenting hydrarthrosis and continuous pain in both knees, accompanied with pronounced anæmia, pallor, and albuminuria in large amount. On the very evening of the injection he declared himself greatly relieved; on the following day he moved his limbs with facility, and the albuminuria had completely disappeared. After eleven days from his entry into hospital, he walked a distance of three kilometres without difficulty.

I have now accumulated a total record of 84 rheumatic patients who have been treated after this method of procedure. I have been also able to compare the results, individual and collective, obtained in the cases of 54 patients who were treated with salicylate of soda, and I believe that I am in a position to affirm the therapeutic superiority of that with colloidal gold: the latter remedy calms the pain, shortens the duration of an attack of the disease, and prevents the development of complications. And it is above all in the cases of rheumatism occurring among young subjects, and in the markedly acute forms, that it presents its maximum of therapeutic efficacy. We will subsequently recur to a description of its mode of application, and the *rationale* of its curative effects; but at the outset a summary of some of the more significant cases and a description of some thermometric curves should prove more convincingly eloquent than long general commentaries.

Obs. I.—*Rheumatism of Malignant Type*.—F. (Jules), æt. 29, artillery soldier. Had formerly suffered from three critical attacks of acute articular rheumatism: the first at the age of 14 years, the second at the age of 18, and the third when he was 22. He entered hospital on April 30th, 1915, on the fifth day of his illness. The temperature was 39.4° (102.9° F.). Pain and

hydrarthrosis in both knees; pains in shoulders; slight albuminuria. On the following days a series of complications developed in succession: great pericardial friction; double pleuro-pneumonic congestion; mitral endocarditis with enormous cardiac dilatation, ameliorated by administration of digitalin; hypertrophy of liver; albuminuria in great quantity; transitory spinal phenomena (pains in the back and legs; Kernig's sign; cephalo-rachidian fluid normal). From April 31st till May 24th had received 8 grammes of salicylate of soda daily. On May 18th we administered an intravenous injection of 5 c.c. of electrargol: no reaction, no subsequent result.

May 25th.—Intravenous injection of 2 c.c. of colloidal gold. The injection was administered in the morning, and was followed by a rigor, extreme tachycardia, and sweats. On the evening of the same day the patient began to show indications of relief. On the following morning the temperature fell to 37° (98.6° F.). It never rose again. During the succeeding days there was extreme polyuria—amounting to 4 litres. The albumin had disappeared from the urine on May 30th. The patient left hospital on June 17th. He was then suffering from no symptoms whatever, but retained a double mitral lesion, well compensated.

Obs. II.—Br. (Jean), æt. 35, infantry soldier. Had entered on the eighth day of an attack of medium intensity (shoulders, left elbow, articulations of fingers of left hand, hydrarthrosis of left knee). Had not taken any salicylate. Persistence of some pains in the shoulders after the first injection; complete cure after an interval of 48 hours following the second puncture.

Obs. III.—S. (Henri), lieutenant, æt. 39, first crisis. Had entered on the sixth day of his illness. Pains in all the limbs; hydrarthrosis of both knees; œdema of right hand and wrist; intense pallor; copious albuminuria. Injection of 2 c.c. on May 29th. After 24 hours, complete disappearance of all pains and swelling, also of the albuminuria. The patient arose from bed on June 3rd, and took a walk of three kilometres, without any pain whatever, on June 8th.

Obs. IV.—S., æt. 20, infantry soldier. Had entered on the sixth day of his illness. The crisis was one of marked intensity (hydrarthrosis of both knees; œdema of right wrist; pains in shoulders; notable proportion of albuminuria). Injection administered on May 29th; subsidence of temperature and disappearance of albuminuria on the following day. Slight relapse (pain and œdema of right wrist) on June 7th. Complete and lasting cure after second puncture.

Obs. V.—D. (Alphonse), infantry soldier, æt. 24. Had entered on the third day of his illness. The crisis was one of medium intensity (hydrarthrosis of both knees).

Obs. VI.—R. (Louis), infantry soldier, æt. 44. Entered on sixth day of illness. Crisis of medium intensity.

Obs. VII.—D. (Claude), infantry soldier, æt. 21. Had entered on the fourth day of his illness. Crisis

of medium intensity; slight hydrarthrosis of both knees; œdema of ankles.

Obs. VIII.—C. (Ferd.), corporal, æt. 19½. Entered on fourth day of illness, crisis of medium intensity (knees, œdema of ankles).

We do not wish to add unnecessarily to the length of this article by multiplication of recorded observations and descriptions of thermometric curves bearing a general family resemblance. But there are five cases which deserve to be placed in a prominent position on account of the fact of having been each accompanied at the outset with the characteristic signs of endocarditis.

Two of those patients had entered hospital with muffling of the sounds of the heart, and a slight prolongation of the first sound; the third presented a slight systolic bruit at the apex, of organic source, which lasted for two days; in the fourth case, there was also a mitral systolic murmur, which presented a rasping character; in the fifth case, we detected the presence of a pericardial *frottement*, and a systolic murmur located over the apex. Every one of these patients was treated with colloidal gold, and after some days there actually remained no traceable sign whatever of cardiopathy. We will merely sketch the course of two of these cases:—

Obs. IX.—P. (Henri), æt. 20, infantry soldier. First crisis; entered hospital on eighth day of his illness. Had already been treated during four days with salicylate of soda (3 to 4 grammes). Moderate fever (38°=100.4° F.). Pains in knees and shoulders; vertebral rheumatism, with extreme rigidity of vertebral column. Suffering greatly; is completely helpless and incapable of the least voluntary movement. Softening of the cardiac sounds; slight prolongation of first sound. July 16th; injection of 1.5 cc. of colloidal gold; on following day considerable diminution of the pains. But we discovered at the apex a slight systolic blowing murmur. Although the fever had subsided and the pains had disappeared, we administered a second injection on July 18th, hoping thereby to cure the endocarditis which was then in course of evolution. On the 20th, the bruit had great diminished; on the 21st it had ceased to exist; a little of the muffling of the sounds of the heart persisted for some time, but it gradually disappeared. We kept the patient under observation for some time, and his chest was auscultated by several of our colleagues; but not the least further trace of cardiopathy was ever discovered subsequently.

Obs. X.—B., æt. 28. First attack. Entered hospital on the ninth day of his illness. Violent crisis (knees, elbows, shoulders). Muffling of cardiac sounds; pericardial *frottement* in the mesocardiac region; slight murmur at the apex. Injection of 2 cc. of colloidal gold on August 4th; persistence of elevation of temperature; slight subsidence of the cardiac symptoms. August 6th: the cardiac sounds still remained muffled; the *frottement* and murmur have disappeared. Second injection administered on August 6th; rapid fall of fever; complete disappearance of all signs of endocarditis. The patient left his bed on August 8th. Slight relapse from 13th to 16th of August, which was rapidly extinguished by administration of another injection.

The above series of examples demonstrate the clinical fact that by the administration of intravenous injections of colloidal gold we, as a general rule, bring about a rapid fall of temperature, and shorten the duration of the rheumatic crisis—and more especially of the convalescence—while at the same time we avoid cardiac complications. In our

cases we habitually got the patient to leave his bed at an early date—at the close of two or three days of apyrexia.

In some of our cases a copious intra-articular effusion persisted. Accordingly, it was necessary, after the fever had subsided, to puncture with all the precautions of asepsis. Then we found, as a general rule, that there was no further tendency to the collection of the fluid; and we proceeded to raise the patients from bed one or two days after the evacuation. The two following cases present in this connection demonstrative observations of special value.

Obs. XI.—L., (Alexis), æt. 40. First crisis. Entered hospital on June 26th, on the sixth day of his illness. Acute rheumatism, with hydrarthrosis of both knee-joints. The fever subsided in eight days, after four injections of colloidal gold. The patient retained the bilateral hydrarthrosis, although now quite apyretic. Puncture of both knee-joints (35 to 40 grammes of citron-coloured liquid in each) on July 6th. Left bed on July 7th. No recurrence of the articular effusion; no muscular atrophy.

Obs. XII.—R. (René), æt. 30. Second attack. Entered hospital on July 19th, on the twelfth day of his illness. Temperature 39° (102.2° F.); muffling of the cardiac sounds; hydrarthrosis of both knee-joints. Two injections of gold (July 19th and 20th). Disappearance of cardiac signs (apyrexia) on July 22. July 20th we had punctured both knees (125 cc. from right joint; 110 cc. from left). No reproduction of the articular effusion; no muscular atrophy.

In the subacute varieties of rheumatism, in chronic cases of old standing, and in aged patients—also in those cases who have reached the tenth or fifteenth day of the disease, and after insufficient treatment, our methods are still effective; and prove superior to salicylate treatment in all the more unfavourable varieties of cases. The cure is, however, less rapid, and it is often necessary to administer five or six injections; a little of the stiffness and swelling of the joints may also persist for a considerable period. Nevertheless, we have seen many patients who had still continued, after a prolonged course of salicylate treatment, to present a high temperature, and pains which were aggravated by the slightest movement; yet in whose cases a rapid cure was effected by the administration of one or two injections of gold.

As in the case of all medicaments of pronounced activity, colloidal gold may provoke serious accidents, and we have ourselves had to deplore the occurrence of *one fatality*.

Obs. XIII.—P. (Benoit), aged 30. First attack. Entered hospital July 24th, on the fifth day of his illness. Polyarticular rheumatism (knees, tarsal regions, wrists). Great suffering. Rapid heart's action. No albumin in urine. Axillary temperature 39.5° (103.1° F.). Injection of 2½ cc. of colloidal gold on July 25th at six o'clock. Violent reaction; extreme agitation; screaming; delirium. At the end of two hours the patient falls into a state of collapse; wretched pulse, cold extremities, and coma. Death took place at 11 o'clock at night, five hours after the injection.

At the autopsy we discovered a great variety of pathological conditions.

1. *Recent lesions*, associated with the acute terminal stage; meningeal and cerebral congestion; vascularisation of the meninges; punctiform hæmorrhages in both grey and white substances of the brain; punctiform hæmorrhages in both leaflets of the pericardium; slight serous pericardial effusion; renal congestion.

2. *Lesions of older standing*: heart soft, flabby, and fatty; inflammatory thickening of mitral and tricuspid valves. These alterations are undoubtedly referable to rheumatic infection. But over and above them we also discovered *renal lesions of old standing*. Both kidneys were small, lobulated and sclerotic, sclerous bands penetrating from the capsule in the direction of the parenchyma. The cortical substance was atrophied, especially in the left organ. The pyramids were destroyed and replaced by sclerous tissue in the left kidney, down to the level of the inferior pole.

Thus the patient presented old renal lesions of a nature which had made him exceptionally susceptible to the influence of any form of intoxication. Besides, when we commenced to treat him he had already been suffering from high fever; we also administered a large dose of the medicament—more than the 2 cc.—as it had occurred to us that by increasing the dose we should secure a more rapid and complete effect. We have now arrived at the conclusion that, in case of the first injection at least, the quantity should not exceed 1 or 1.5 cc. We feel quite convinced that by acting with prudence and after carefully testing the individual susceptibility of the patient, we will be enabled to avoid the recurrence of a similar accident. But the occurrence of a single unfortunate result, however deplorable, should surely not induce us to abandon the use of a therapeutic agent which has proved itself superior to all others previously known, and which appears capable of successfully warding off all cardiac complications. (a)

By the record of those few observations we have indicated the principal effects of intravenous injections of colloidal gold on the course of articular rheumatism. It now remains for us to describe in their entirety the *technique* and mode of action of our special treatment.

(To be concluded in our next.)

ORIGINAL PAPERS.

TWO CASES OF INTESTINAL HÆMORRHAGE IN THE NEWBORN.*

By MABEL M. CRAWFORD, M.D.,

Late Acting Assistant Master, Rotunda Hospital, Dublin.

In the Rotunda Hospital, during six months of last year, there were two cases of intestinal hæmorrhage occurring in infants during the first week. I think it worth while to report these cases, not only because the condition is not very common, but because one of the infants died and I was able to examine the abdomen *post mortem*.

In the first case the child was a small girl—weight at birth 5lb. 2oz., length 18½ in., apparently healthy. There had been no complications during labour, which had lasted altogether 18 hours. The mother was a primipara of 28 years; she was not in good health, showing œdema of the legs, vulva and face, and passing a quantity of albumin in the urine. For this reason she was given no food, but was kept on water only from the time of her admission until after the child fell sick.

The first hæmorrhage occurred with a motion on the second night—*i.e.*, about 36 hours after birth—and two more occurred before morning. Nursing

(a) We have now administered more than 200 injections of colloidal gold, not only in cases of rheumatism, but also in those of other infections, both medical and surgical, including cases of gaseous gangrene accompanied by deplorable general conditions. The accident above recorded is the only unfavourable one we have hitherto met with.

* A paper read before the Section of Obstetrics and Gynecology, Royal Academy of Medicine in Ireland, February 11th, 1916.

was stopped, and the child was given water alone by the teaspoon. The next morning the child vomited once—brownish material, small in quantity.

It being decided to use horse serum, and in subcutaneous doses of 2 cc. each, one dose was given that morning and two more at intervals of twelve hours. During the day the child had adrenalin, two-hourly and in one minim doses, and frequent sips of cold water. The hæmorrhage recurred repeatedly during the day, and by the evening the infant was very weak. From this time she was given milk with brandy.

On the fourth day there was one slight hæmorrhage. The child had become steadily whiter and feebler. She now had that peculiarly immobile, waxy appearance of extreme anæmia, and without further bleeding she died on the following day.

At the *post mortem* examination an ulcer was found on the duodenum very near the pylorus. Seen from the outside the ulcer showed as a grey circular patch, perhaps 2 mm. in diameter, and around this the blood vessels were deeply injected. A blood clot filled this part of the duodenum, and at the place of ulceration the wall was found to be extremely thin. There was neither air nor free fluid in the abdominal cavity, nor were there any adhesions about the ulcer. No other lesion was found.

On thinking it over, it seemed to me that it would have been better if I had given a larger dose of serum to start with, so in the next case I gave 5 cc. of serum as soon as possible after the first hæmorrhage.

In this case, also, the child was a girl—7½ lbs. weight, length 21 in.—and the mother was a healthy multipara of 39 years. The first hæmorrhage occurred about 52 hours after birth. I was unable to obtain horse serum on this occasion, so used anti-diphtheric serum, giving 5 cc. straight away subcutaneously. This was early in the evening, and during the night there were two more hæmorrhages. The next day there were three slight hæmorrhages and a second dose of serum was given, rather less than 5 cc., and after this there was no more bleeding. Adrenalin was used in this case also.

The child was given nothing but water by the mouth until 16 hours after the last hæmorrhage. By the fifth day she had apparently recovered altogether, and nursing was resumed without further trouble.

It is always difficult to compare two cases, but at the time it did not seem to me that the second child was any better off than the first during the early stages, except that she was a larger and stronger infant. In each case the illness began with three fairly large hæmorrhages within twelve hours, and whether the subsequent developments were due to the difference in the physique of the infants, or whether in the second case the hæmorrhage was really controlled by the larger dose of serum, it is impossible to assert.

With regard to diagnosis, a point of importance is the almost entire absence of vomiting. Diagnosis would seem to rest solely upon the occurrence of massive hæmorrhages per rectum.

Although intestinal hæmorrhage is not so very uncommon in the newborn, yet I cannot find record of any cases of duodenal ulcer in infants under one month old. Veeder, of St. Louis, reported five cases a year ago occurring in infants between one and six months of age. He considered the ulceration as indirectly due to alimentary decomposition, because he found it associated with chronic intestinal disease. In all his cases the hæmorrhage was associated with vomiting.

In an infant whose life is measured in hours it is difficult to conceive of an infective origin of the ulcer. I would suggest that the trouble might be due to a premature gastric secretion, and that probably the acid of the gastric juice is to blame rather than its peptic quality, for if pepsin can digest duodenal mucous membrane, why does trypsin never do so a little lower down? The duodenal mucosa is irritated by the unaccustomed hydrochloric acid, and presently eroded. The erosion proceeds until some vessel is opened and bleeding begins. If conditions be unfavourable, hæmorrhage will now continue until the child is bled to death; but in a favourable case the blood issuing from the small vessel will clot, so that the clot covers the injured area and, protecting it from the gastric secretion, allows it to heal.

A healed duodenal ulcer has been found *post mortem* in an infant five months old.

Of the immediate complications of duodenal ulcer, perforation is rarely met with in infants, while hæmorrhage is the usual sequel. Payr, of Leipsig, attributes this to the fact that the ulcer forms, as a rule, on the posterior wall of the duodenum, due to gravitation of the HCl in the recumbent position of the infant. It is well known that in adults ulceration of the anterior wall of the duodenum leads to perforation, whereas ulceration of the posterior wall leads more commonly to hæmorrhage.

With regard to treatment, we have three objectives:—

- (1) To avoid stimulation of the gastric secretion;
- (2) To induce coagulation;
- (3) To support the infant's strength;

and the points of treatment which appear to me the most important are the immediate administration of serum subcutaneously (I have no experience of its use by the mouth) and in large doses, repeated once or twice if necessary, the giving of nothing but water by the mouth, and the maintenance of absolute quiet and warmth.

The value of adrenalin I do not know; and as to surgical interference, it hardly seems justified until the medical treatment has been given a trial. If that fails it is, as a rule, too late to operate.

I wish to thank Dr. Tweedy for his courtesy in allowing me to report these cases; they occurred during the months of his Mastership at the Rotunda, and were treated under his direction.

RECENT WORK ON THE BACTERIOLOGY OF RHEUMATOID ARTHRITIS AND ITS TREATMENT.

By A. E. VIPOND, M.D.,

Senior Physician to the Montreal Children's Hospital, Montreal.

In the year 1906 I read a paper, in the Section of Pediatrics, at the annual meeting of the British Medical Association held in Toronto, entitled "The Early Diagnosis of Infectious Diseases by the Recognition of the General Involvement of the Lymphatic Glandular System" (*British Medical Journal*, December 15th, 1906). Since that time I have repeated and enlarged upon this theory and presented a paper before the Canadian Medical Association, held at Montreal, June 7th, 1911, entitled "Scarlet Fever, a Preliminary Note on a Specific Micro-organism" (*Canadian Medical Association Journal*, July, 1911). In June, 1914, Dr. J. Hayne, of South Carolina, chairman of the pellagra committee in connection with the 29th annual meeting of the Conference of State and Provincial Boards of Health of North America, held in Washington, D.C., June 19th-20th, 1914, read

a paper for me entitled, "Some Experiments in the Production of Pellagra in Monkeys" (reprinted report of Pellagra Committee, State of Provincial Board of Health of North America, 1914). Recently at a meeting of the Montreal Medico-Chirurgical Society at which Dr. L. J. Rhea read a paper on "Some Recent Findings in Hodgkin's Disease," in the discussion which followed I made the statement that I had recovered a short bacillus from the enlarged nodes of a patient suffering from lymphatic leukaemia. I inoculated a monkey with a broth culture and in 72 hours the glands were enlarged and a large ecchymosis was present over the abdominal wall. The blood changes were marked and the monkey died in less than 80 hours, and from the nodes I recovered the same bacillus. A vaccine was prepared from this bacillus and after the first inoculation the patient's nodes reduced fully 50 per cent, in size and in about one month's time he returned to work. However, I left town and the vaccine was not given regularly and the patient died about four or five months later. (*Canadian Medical Association Journal*, May, 1915.)

In the above papers I maintained that the lymphatic nodes are Nature's incubators where organisms multiply and thrive and send out into the blood stream chemical toxins which accumulate and produce the disease, the symptoms depending upon the chemical characteristics of the toxin or toxins derived from the micro-organisms which are situated in the enlarged nodes. In acute infectious diseases the lymphatic nodes are enlarged and are painful on pressure. This enlargement begins shortly after the organism enters the system by way of the torsils, which I regard as the portal of entry. I have made a diagnosis of incubating measles fully ten days before the rash developed. I have found the nodes to be enlarged in all acute infectious diseases. In the many cases of pellagra which I have examined I have found the nodes enlarged in nearly every instance.

In rheumatoid arthritis many observers have found bacilli, streptococci, etc., in the blood, the joints and in pyorrhœa alveolaris. In the Special Rheumatism Number of *American Medicine* for June, 1915, is an admirable and full description of rheumatoid arthritis. The articles in this number have been written by the pioneers and most advanced research workers on this subject, but in the medical literature I cannot find any reference to any organism being recovered from the nodes of patients suffering from rheumatoid arthritis. I examined the nodes of patients who suffered from this malady and found them to be enlarged in nearly every instance, the largest being the vertical inguinal nodes of the left side, in many cases as large as a small walnut. In one or two instances, however, I could not palpate a node in any part of the body.

The following shows the bacteriological findings in twelve cases. I may state here that I have found two organisms which I am inclined to believe are associated organisms and that both take a part in producing the signs and symptoms of rheumatoid arthritis. I obtained diplococci or small thin bacilli, either alone or combined, in ten cases, the other two cases gave negative results. Altogether I am inclined to think that the diplococcus is the primary organism and that the bacilli play a secondary part. In my next paper, which will appear shortly, I shall give a full description of these two organisms. However, I may state here that the diplococcus which I obtained from the nodes of these patients is unique and stands in a class by itself. The primary culture is of very slow growth, taking three days to appear as a delicate sparse growth on the surface of the blood serum.

The bacillus grows fairly quickly; it is a short, thin, spore-bearing bacillus.
